THE ARCHITECTS' & BUILDERS' JOURNAL.

*A Weekly Journal for Architects Surveyors
Builders and Constructional Engineers.*

It is our aim, our ambition, our aspiration even, to build our Journal worthily and well, not for the hour only, but for future years; for the few men in the forefront of an enduring and a laborious art; for the disciplined ranks of a distinguished profession; for the young men—Architects to be—and for all who love a clustered column or a flying buttress, a traceried window or a Greek frieze; for the man, too, who honestly plumbs a jamb.

CAXTON HOUSE, WESTMINSTER

CONTENTS.

See also Concrete and Steel Section.

ABATEMENT, SMOKE, 341.

Academy, Royal, Church Architecture at the, 519.

Acanthus, The Greek, 269.

Acoustics, Architectural, 547, 550.

Adam Period Fireplace, 179.

Additions to Clifton College Chapel, 420.

London Architecture in Relation to Roads and Bridges.

THE Report of the London 'Traffic Branch of the Board of Trade, recently published, has more relation to architectural subjects than would appear at first sight from its title. For increased accommodation for traffic means new streets or the widening of old ones, which implies the removal and re-erection of the

buildings which line them or, what is equally important, the placing and aligning of buildings so that they shall not form obstacles to future enlargements. And, London lying on two sides of a river, the dimensions and placing of new bridges, or the enlargement of old ones, enter into the problem, and form in an architectural sense a very important element in it. The study of such a Report compels us to regard London as a whole, as in itself a kind of architectural design, got together in the past in a very haphazard and accidental kind of way, but capable of being treated with more comprehension and foresight in the future.

As far as roads are concerned, the necessity for this comprehensive action on a predetermined scheme is the burden of the Report, and it is graphically illustrated in the first of the maps appended to the Report, which shows in dark grey the existing main roads out of London, and in red the proposed new ones. The main object in the new roads is to increase the number of large roads forming direct through routes from north to south and from east to west, or from the centre to the country in these directions. Some of the suggested new roads in the map afford object-lessons as to the importance of exercising foresight in regard to possible future routes. Among the existing roads leading northward out of London are Cambridge Road and the road to Enfield, distant from each other about an average of a mile and a half, but between these is shown in red a "new Cambridge Road" leading northward in the same direction, in fact crossing the existing Cambridge Road at Cheshunt, and meeting it finally about two miles further north. Why this addition of a third road north between two existing ones? We turn to the text of the Report for explanation, and find that the difficulty and delay in rendering the two existing roads adequate, by pulling down houses and setting back the building line, would be so great that it would be preferable to drive a new wide road through the space between them that is not yet built upon. This is only a sample of what is likely to happen in other cases. As is remarked in the introduction of this portion of the Report, "there is no time to be lost, and unless local co-operation can be ensured as town-planning schemes mature, the possibility of constructing some of the proposed roads may vanish, leaving it to the next generation to seek other routes for the growing traffic, and to construct or widen roads at greatly increased cost." Some of the districts through which the proposed new main roads would pass have already sketched out "town-planning schemes," but none have reached a stage at which it is known whether, and to what extent, their roads can be brought into conformity with the general scheme. Surely this is a most extraordinary and

illogical state of things, that isolated road schemes should be under consideration in suburban districts, without any attempt to see how they will work into a general scheme for main lines of traffic. The only remedy for this is to have a central authority who should confer with local authorities, so as to arrive at some understanding as to the precise line to be adopted for main roads, and the manner in which the local scheme may be adapted to form part of a general scheme of suburban planning. In the meantime, to quote again from the Report, "a direction in which assistance from public funds towards the improvement of roads near London might be given with the greatest advantage, would be in arresting the growth of obstructions which, if suffered to increase, would add to the difficulty of widening existing roads. *It is most desirable that building lines should be prescribed without delay on all main radiating roads.*" The italics are ours; the advice cannot be made too prominent. It is then suggested that where local authorities are unable to meet the expense of the claims for compensation which the laying down of building lines may give rise to, assistance from public funds would save a much larger expenditure a few years hence.

For the same reason no doubt as in the last-named case, we find on the suggestion map a new road westward from Paddington to Uxbridge, continuing the line of Euston Road and Marylebone Road, which in themselves look like the beginning of a good east to west main road, but have no adequate continuation; and it seems that some authorities are disposed to destroy even the present advantages which those roads possess for widening, in the existence of fore-courts in front of the building line. The short story of this affair, as given in Mr. W. E. Riley's appendix to the Report, is astounding. In connection with some new building in part of the Euston Road, the L.C.C. superintending architect defined the building line as that of the main line of buildings behind the fore-courts or gardens. The Tribunal of Appeal reversed this decision, and defined it as the line of the one-story shops which project in front of some of the houses up to the back line of the pavement. The High Court confirmed this decision, but the Court of Appeal reversed it, and the House of Lords upheld the Court of Appeal's decision. Thus it appears that, but for the Court of Appeal and the House of Lords, we should have had a precedent set for destroying the whole opportunity of converting Euston and Marylebone Roads into the commencement of a wide route westwards out of London.

Something might perhaps have been said in the Report, which deals mainly with the larger question of main roads through and out of London, about the necessity for minor improvements in the way of direct routes. London is still full of small *cul-de-sac* streets which seem as if they ought to lead from one important thoroughfare to another, but lead nowhere; and one is reduced to roundabout routes from one important street to another, where there ought to be direct communication. It is a kind of improvement which could only be carried out by very slow degrees, but it is a subject that ought to be thought of.

The most interesting part of the Report in an architectural sense is that which refers to proposed new bridges, as these must materially affect the architectural aspect of London, though this side of the question, naturally perhaps, is not touched upon in a Report dealing ostensibly with

questions of traffic. Still, seeing that the President of the Board of Trade is known to take a great interest in the architectural improvement of London, one might have hoped that this consideration would not have been entirely lost sight of. In regard to the proposed St. Paul's Bridge, we learn from the Report that the bridge is to have "five steel arches"; this is referred to as a thing settled, and there is only too much reason to fear that we are to have another engineer's bridge of the same type as Blackfriars. Every effort ought to be made, by those who have any influence with the authorities and the public, to get something better than this done, and to insist on the employment of an architect to design the visible portion of the bridge, as far as appearance and details are concerned. It would be far better to have a granite bridge, to repeat if possible the monumental majesty of London Bridge. If Southwark Bridge is also to be rebuilt as a steel bridge (as to which nothing is said in the Report), there may perhaps be something to be said in favour of making the St. Paul's Bridge a steel one also; we should then have three steel girder bridges in succession, flanked at either end by the monumental structures of Waterloo and London Bridges; that would be a symmetrical kind of arrangement, though we should much prefer to see the new bridges both built of granite, and their effect as additions to London architecture would be much finer. If, however, we must have the inferior effect of a steel girder bridge thrust upon us, let it at least be an artistically designed one. The new Vauxhall Bridge has shown that, with the assistance of an architect, it is possible to make a steel girder bridge artistically interesting and beautiful, but that end will not be attained if the design is left to an engineer. The Report takes cognizance of the dispute as to the line of St. Paul's Bridge, and also refers to the recent decision in regard to it as a point settled, and to the evidence of the three architects called in by the Corporation, who confirmed that body in their intentions. The Report dismisses the subject with the remark that, "Taken in conjunction with the proposed widening of the churchyard, the undertaking will be a metropolitan improvement of the first magnitude." It might have been so; it has been spoiled.

Southwark Bridge has undoubtedly been injured for practical purposes of traffic by the heavy gradients both of the bridge and its approaches. It was built at a time when the subject of gradients was not so carefully considered as it is now. But the bridge itself is a remarkable structure; more so than is generally recognised. It was built in 1814 from the designs of Rennie, the designer of London and Waterloo Bridges, and is remarkable as being a cast-iron structure, the spans of which are actually built as arches, in the usual sense of the word; arches with voussoirs of cast-iron instead of stone or granite. They have covering pieces at the joints, and the arches are connected by lateral cross-bracing; but they are arches and not trussed girders, and it is such an unusual and bold experiment in iron construction that it is a pity to lose it. The treatment of the details—railings, etc.—is simple and good, and the whole structure has a very grand effect when viewed from the steps at the side, below the level of its roadway. There is no doubt, however, that in consequence of its bad gradients it must be removed and rebuilt; and to rebuild it on the same principle would be a rather old-fashioned proceeding. It is to be feared, however, that it will not be replaced by anything so effective and so dignified in appearance.

The suspension bridge at Lambeth has long been under interdict for heavy traffic, and there is no doubt that it ought to be replaced by a more stable structure. In its design, in an architectural sense, there is nothing to complain of, for the large standards over which the chains are carried are frankly treated as iron-work, with no concealment or false ornament, and, simple as it is, it is in far better taste than the gewgaw and pretentious suspension bridge at Chelsea, or the absurd treatment at the Tower Bridge, where the suspension chains are carried apparently across small stone-built offices at the approaches to the bridge, which the chains would pull down at once if their apparent support was the real one. The real reason why Lambeth Bridge has been left so long is because at present

it is not on any main line of street traffic. It is now proposed to apply to Parliament during the present year for powers to erect a new bridge, which it is proposed to make a steel bridge 48 ft. wide. As a reason for urgency it is claimed that this bridge is on the direct line of route from Victoria to the Tower Bridge. This is hardly accurate; on the Surrey side it is the most direct line of route to London Bridge, hardly to the Tower Bridge; and on the Middlesex side there is practically no route at all to it from Victoria, from which it is separated, after Horseferry Road is traversed, by a congeries of small streets at all kinds of angles. To make it really useful in the manner proposed, the straight part of Horseferry Road would have to be widened and then continued in a straight line to Victoria Station. The bridge would then make part of a really important thoroughfare, so important, that we are disposed to think the proposed width of 48 ft. would ultimately be found to be inadequate. But a large new street between the bridge-head and Victoria is an absolute necessity if the bridge is to play this important part in London traffic.

The section of the Report dealing with bridges concludes with a recommendation of the proposals which have been made (not by any authority so far) to remove Charing Cross Station to the other side of the river and substitute a wide bridge for general traffic for the present railway bridge. It is indeed high time that this idea should be seriously taken up by the London County Council, for it would be one of the greatest possible London improvements. Considering the great and increasing importance of Waterloo Station, it is perfectly absurd that there should be no means of vehicular access to it from central London except by going a long way round by the Strand and Waterloo Bridge one way, or by Parliament Street and Westminster Bridge the other way; so absurd that it seems a wonder that we have put up with it for so long. No improvement suggested in the Report is of more importance than this, and it should in fact have been rather more strongly emphasised.

Kingston Bridge.

IT is announced that the work of widening Kingston Bridge, long talked of, is to be put in hand early this year. The present bridge is only 24 ft. wide between the parapets; it is to be increased to 55 ft.; wider than necessary for present purposes, for the traffic over the bridge is not very large; but it is as well, no doubt, to provide for any possible future changes in the neighbourhood. It is satisfactory to reflect that the idea at first entertained of actually destroying this fine stone bridge and substituting a steel one, under the usual plea of economy, has been abandoned in deference to the strong representations that were made by various artistic and architectural societies and individuals, and it is now stated that "one of the conditions insisted on is that the present architectural features of the bridge shall be retained." This is rather a vague sentence; we are not told who "insists," nor exactly what is meant by "retaining the architectural features of the present bridge." The suggestion which was made by those who wished to save the situation was that the actual facing stones of the present bridge could be taken down, and re-erected as the facing of the widened structure. There is no difficulty in doing this, and by this means the architectural appearance of the present bridge, as a part of the Thames scenery at this point, would be maintained. It must be remembered that no little of the beauty of the lower Thames is derived from the fine character of its eighteenth-century stone bridges, and a new bridge, even of stone or granite, has not the same effect or the same associations as the old one. It is important therefore that we should have the actual masonry of the existing bridge replaced, and we do not feel any assurance that this will be done. The phrase about the "present architectural features" may only mean that we are to have a modern restoration; and the statement that the work is to be carried out under the direction of Mr Mott, "the architect for the widening of Blackfriars Bridge," prompts the

observation that Kingston Bridge is a very different matter from Blackfriars Bridge. The latter is essentially an engineering structure, and its widening could interest no one except in a structural sense. Kingston Bridge is an erection of architectural beauty and interest, and an architect ought to be employed to see that these qualities are preserved.

A Hampshire Statue.

VISITORS to Petersfield, in Hampshire, may remember the curious drab-coloured statue which occupies a position in the centre of the Market Place, opposite the church. This statue, says the "Morning Post," formerly belonged to Lord Hylton, but a few months ago, when his Petersfield property was disposed of, it was purchased by the Urban District Council at what was regarded as "a bargain price." The statue is cast entirely of lead in from 15 to 20 pieces, and its subject is William III. of England, mounted on horseback. The statue has an interesting history. In 1731 a movement was started in London for the erection of a statue to William, but though funds were forthcoming the scheme was vetoed by the Common Council for political reasons. This caused much comment throughout the country at the time, and as a protest equestrian statues to the King were erected in several parts, among the most important being Rysbrack's equestrian figure at Bristol and Scheemakers' at Hull. The Petersfield statue, the sculptor of which is unknown, was erected by Sir William Jolliffe, then member for the town, and it was gilded and placed in front of his house in the New Way. The figure is attired as a victorious Roman general, with a wreath of bays about his forehead, seated on a rearing horse, which is kept in position by an iron prop. In 1815 it was moved from the New Way to its present position, and on that occasion it was given a coat of drab paint, which has been renewed from time to time. Soon after its recent purchase it was closely examined by Mr. H. Inigo Triggs, A.R.I.B.A., of Liphook, who found that it was in such a state of disrepair that it might collapse at any time. Many people interested in this survival of leaden statuary were alarmed at the prospect, and it has now been decided to appeal for £350 in order to restore the statue in accordance with an expert's specifications. The appeal is signed by Captain P. W. Seward (Chairman of the Urban District Council) and Mr. Inigo Triggs (who is acting as hon. secretary). An effort is to be made to remove the drab paint, but no decision has been arrived at as to whether the statue shall be gilded again or bronzed.

A Real London University.

FOR some years past, we have lost no opportunity of urging the necessity for providing London University with a worthy building. It has always seemed to us to be no less than scandalous that a university with so fine a reputation should be homeless, and that London, lacking worthy and dignified university buildings, is to that extent lamentably and disgracefully incomplete. It is most humiliating to be compelled to tell the enquiring foreign visitor that the University of London is a lodger on sufferance in the Imperial Institute. At length London, probably shamed into activity by the examples of provincial cities, is about to take action, or so at least it may be supposed from the tenour of the fourth report of the Royal Commission on University Education in London, of which the substance is printed in another part of the present issue. That report seems to leave no option. "We think," say the reporters, "that whatever its future constitution may be, it is a matter of national importance that the University of London should be recognised as a great public institution." The discovery, though somewhat belated, is none the less welcome, and the same may be said with equal emphasis of the deduction from it: "We think it is fitting and right, and will be universally accepted,

that such an institution should have for its headquarters permanent buildings, appropriate in design to its dignity and importance, adequate in extent and specially constructed for its purposes, situated conveniently for the work it has to do." Further—as if in confirmation of what we have said as to the stimulus of provincial example—it is added that "a great hall will be required for university ceremonies and for the many important occasions—such as the meetings of International Congresses and other great educational gatherings—when it is fitting that the university should act as host. The McEwan Hall in Edinburgh and the Whitworth Hall in Manchester are worthy of the universities to which they belong, and even in so comparatively small a town as Reading a spacious hall for academic assemblies was built in 1906. But for the University of London, founded in 1836, the only accommodation of the kind at present available is a temporary wooden structure erected in 1887 for the opening of the Imperial Institute by her Majesty Queen Victoria. It appears to us totally unfit for the uses it has to serve." The addition of that last sentence is rather perplexing. One is at a loss to conceive whether it betrays an absence of all sense of the ludicrous, or whether, on the other hand, it should be regarded as a master-stroke of sardonic humour. On presentation-day, when hundreds, in cap and gown, assemble in a wooden shed to receive their degrees, it is difficult to tell whether the predominating feeling is disgust or amusement at the incongruity of environment. A proper development of the sense of humour should years ago have saved London from the shame of having no settled abode for its university; but, by way of compensation, we should now get a bigger and a better building that would formerly have been probable. The reporters very naturally refer to the question of site. They think that "as large a site as possible should be obtained in a central position and buildings erected for a reconstituted university, which would be the visible sign of its recognition and acceptance as a great public institution." The site question is pretty certain to give rise to controversy. As our contribution towards a solution of this important problem, we would suggest, off-hand, that the site of the old General Post Office Buildings would be in most respects eminently suitable, and would be quite as truly central and accessible as, say, Kingsway, which also suggests itself as an appropriate situation.

Our Edition de Luxe.

THE annual special issue of this Journal is now on sale, price one shilling nett. The leading feature is a series of examples of Garden Suburb Houses, selected from Hampstead and Gidea Park. Of these representative designs, forty plates are given, each plate showing specially prepared plans, and special photographs of the elevations. The Garden Suburb movement represents the first definite and practical expression of the town-planning movement, and, *a fortiori*, an earnest endeavour to give architectural character to comparatively small dwellings. To what extent this attempt has been successful our special issue affords, for the first time, adequate means of forming an opinion; the examples having been selected quite independently, and purely on their merits. Students of town planning, and of the æsthetic and other problems involved, will therefore find this comprehensive set of plates invaluable. The issue contains also a rapid review of the architectural events of the year; an important special section in which the most notable buildings of the year are described and illustrated; and another section in which are shown some of the most important examples of reinforced concrete construction in 1911. This sumptuously printed volume, with its wealth of fine half-tone photo-engravings, printed on art paper, should be in the hands of every architect, builder, and town-planner. Orders should be forwarded without delay, as the volume cannot be reprinted. Former special issues have been rapidly exhausted, and have consequently changed hands at greatly increased prices. Hence the wisdom of securing copies while they are to be had at the original charge.

New Year Honours.

THE New Year Honours List does not, so far as we are aware, contain a single name that is of special interest from our particular point of view, except that of Mr. Courtauld Thomson, who is a director of Holloway Brothers, Ltd., and of the Limmer Asphalte Paving Company, Ltd., who receives a knighthood. There seem to be three main reasons for conferring these distinctions. There is the purely personal reason, as when a man attains to distinction in some particular line, whether it be of industry, talent, or philanthropy; the political expediency reason, as when a man is rewarded upon partisan considerations, whether of personal service or of money contributions; and what may be termed the institutional reason, as when the recipient is a leading representative of his profession. There are, of course, other motives, some of them more or less casual or accidental. In the present instance, learning has been recognised in the persons of a few more or less eminent men of science, and (very doubtfully) literature in the bestowal of knighthoods on one or two writers; and Art is honoured by the knighthood bestowed on Mr. Frederick Wedmore, the art-critic and authority on etchings. Architecture, however, seems to have been for the nonce ignored.

The Loan Exhibition at Burlington House.

THE Royal Academy contrive to keep up the interest of these winter loan exhibitions in a surprising manner.

After all that we have seen there already, the present exhibition has still a new interest, divided mainly between Reynolds and the late Mr. Abbey. The first room is devoted entirely to Reynolds, and shows him in a new, or at least unusual light, as eight of the pictures are ideal or emblematic figures designed for the west window of New College Chapel at Oxford. At that time nothing was known in England as to the special character required for stained glass design; the window was treated just as if it were a large easel picture, and as a stained glass window it is a failure; but the subjects for it, seen as pictures on canvas, are admirable; the figures of "Faith," "Justice," "Hope," etc., have great dignity and nobility of style and design. The two finest things in the room, nevertheless, are portraits in Reynolds's usual style; his well-known portrait of himself, belonging to the Royal Academy, and the group portrait of the Brummel children, one of whom afterwards became celebrated or notorious as "Beau Brummel"; an open-air picture which seems to combine the best qualities of Gainsborough and Reynolds. To the works of Abbey three galleries are devoted, one containing oil paintings, including "O Mistress Mine," which contains one of the most beautiful and expressive female heads ever put upon canvas; the two others are devoted to Abbey's immense series of studies of Shakespeare characters in black and white, mostly pen drawings. These were done for a series of Shakespeare articles in one of the American illustrated magazines. We do not by any means always agree with his conception of the characters, but the drawings show a great power of expression and composition in pen and ink, and argue a wonderful power of rapid work, to have been the production of one man, as an offshoot to his more serious work in oil-painting.

The second room, as usual, contains a good many works of the Dutch school, among others a fine Gerard Dow, two or three examples of Rembrandt's lesser works, and an interesting work by the little-known sixteenth-century painter Henri de Bles, called "Civetta" (under which name he appears in the catalogue), an "Adoration of the Magi," remarkable for its curious and carefully painted detail of costumes and architecture. The third room contains one or two doubtful Titians, a beautiful half-length portrait of a lady by Hoppner, one or two very interesting Isle of Wight landscapes by Turner, and a Richard Wilson landscape not quite in his best way. In the fourth room we have three Morlands, Kneller's charming portrait of Nell Gwynne (in which Kneller shows as a much better painter than his rival Lely, whose portrait of another frail lady hangs next to it); Rubens's large work "The Tribute Money," well known

from engravings; and two landscapes by the French eighteenth-century painter Joseph Vernet, remarkable for their fine effects of sunlight; Vernet is a landscape painter who ought to be better known than he is. Among the miscellaneous contents of the room known as "the water-colour room" is a first-rate Ostade—"Boors Drinking," a composition of many figures, remarkably effective. There are plenty of other pictures of historic or artistic interest. But we rather wish the Academy would follow up the excellent precedent they set some years ago, of devoting one room of the loan exhibition to ancient work of applied art—silverwork, jewellery, ironwork, etc.

New Buildings at Cambridge.

SEVERAL additions to the colleges of the University of Cambridge are now being completed. They include the new buildings for the Museum of Archaeology and Ethnology, in continuation of the Law School, the Squire Law Library and Sedgwick Memorial Museum in Downing Street (Mr. T. G. Jackson, R.A., architect); new literary lecture rooms between the Cavendish Laboratory and the new examination rooms (Messrs. Hubbard and Moore, F.F.R.I.B.A., architects); a new students' block at Ridley Hall (Mr. William Wallace, architect); students' chambers on the western side of Queen's College; and a new court at Emmanuel College on a site to the north-east of Emmanuel Street. In the Museum of Archaeology and Ethnology, on the second floor, has been placed the central part of the old Classic choir screen from Winchester Cathedral designed by Inigo Jones. The fragments were found stored away in the triforium, whence they had to be removed during the repair which is now in progress at the cathedral. Though many parts were missing, enough remained to enable Mr. Jackson to recover the design. There was no place in Winchester for reconstructing the entire screen, even had it been perfect; and the Dean and Chapter have given the central part, for which alone there was room, to be built into this new museum, where it forms a doorway between the part now being built and the future extension backwards.

Southwark Cathedral.

A CORRESPONDENT of the "Times," Mr. Henderson-Livesey, makes a proposal which ought to excite some public interest, in regard to the opening out of the site of what he justly describes as being at present "a hidden cathedral" at Southwark. There is now a line of warehouses between the cathedral and the river; the proposal is that these should be cleared away and a wide space thrown open between the cathedral and the river, leaving the cathedral standing in an open area, bounded by London Bridge, the railway, and the river. This would not only bring the cathedral into sight as a fine object from the river, but would provide an open space in a neighbourhood where it is much wanted. The proposal is one well worth consideration, and should not be lost sight of. The writer goes further in suggesting that this might be regarded as the commencement of a scheme for building an embankment on the south side of the river, similar to that on the north. The erection of the London County Hall necessitates an embankment or quay there; the Southwark scheme would involve making one adjoining London bridge; the work would be crowned by embanking the whole margin of the river between those two points, thus making the river side accessible on both banks, and substituting a quay and a roadway along the bank for the present motley array of warehouses and other buildings, and doing away with the unsightly mud banks seen at low water. What the south bank of the Thames is, between Westminster and Blackfriars Bridges, the north bank of the Thames once was. If the change has had such a splendid result on one bank of the river, it is surely worth while to endeavour to realise the same effect on the opposite bank. One practical result would probably be that the river, with convenient landing-places on both banks, would again become a high way for passenger traffic in steamers.

"CRUNDLE COURT," DORSET. WALTER H. BRIERLEY, F.S.A., F.R.I.B.A., ARCHITECT.
From "Recent English Domestic Architecture."

"RECENT ENGLISH DOMESTIC ARCHITECTURE."

The proprietors of the "Architectural Review" have just published another Special Issue devoted to recent English domestic architecture, price 5s. nett. Like its predecessors of 1908, 1909, and 1910, it embraces a great variety of designs, but perhaps the present issue is particularly noteworthy for including work by lesser-known men, as well as the familiar names of the profession; it is noticeable, too, that there are a large number of houses of moderate size, such as the average man might wish to build. Without exception, the houses are illustrated by means of photographs and plans; which is unquestionably the best manner of presenting such a collection, more especially as the facile artist, with pen, pencil, or brush, is able to give (as we know from the equivocal perspective) an appearance to a house which is quite different from the actual building.

The new volume should be in the hands of all who wish to keep in touch with the latest work of English domestic architects. Though some well-known names are unavoidably absent, there is an abundance of good work included. Mr. Ernest Newton, Mr. Brierley, Mr. Macartney, Mr. Guy Dawber, Messrs. Detmar Blow and Billerey, Professor Reginald Blomfield, Mr. Geoffrey Lucas—to mention a few—are represented by houses never illustrated before by means of photographs. As examples, we give on this page a delightful house by Mr. Brierley, "Crundle Court," Dorset, and on page 1 a sundial on a house at Baldock by Mr. Geoffrey Lucas, this latter illustration being one of many similar details included in the volume.

The issue is excellently produced, and we are glad to draw the attention of readers to a volume so attractive and useful as this one is. English domestic architecture, as carried out by the more capable architects of to-day, is a constant pleasure to study. It stands apart from the domestic architecture of all other

countries by reason of its inherent qualities, its homeliness, and its conspicuous charm; so that a new volume wherein the most recent examples are attractively shown is assured of a wide and cordial welcome at the hands of all lovers, amateur as well as professional, of delightful architecture.

"CRUNDLE COURT," DORSET: GROUND-FLOOR PLAN.

THE HOUSING OF LONDON
UNIVERSITY.

The fourth report of the Royal Commission on University Education in London, which has just been issued [Cd. 6015], deals with the question of the housing of London University. The Commission was appointed on May 26th, 1910, and consists of Lord Haldane (chairman), Lord Milner, Sir Robert Romer, Sir R. L. Morant, Mr. Laurence Currie, Dr. W. S. McCormick, Mr. E. B. Sargant, and Mrs. Creighton. The substance of the report appears below, the cross-headings being unofficial:—

Scope of the Enquiry.

The Commissioners were appointed to enquire into the working of the present organisation of the University of London, and into other facilities for advanced education (general, professional, and technical) existing in London for persons of either sex above secondary school age; to consider what provision should exist in the Metropolis for University teaching and research; to make recommendations as to the relations which should in consequence subsist between the University of London, its incorporated Colleges, the Imperial College of Science and Technology, the other Schools of the University, and the various public institutions and bodies concerned; and, further, to recommend as to any changes of constitution and organisation which appear desirable; regard being had to the facilities for education and research which the Metropolis should afford for specialist and advanced students in connexion with the provision existing in other parts of the United Kingdom and of his Majesty's Dominions beyond the Seas. The Commissioners having been empowered to report their proceedings from time to time, submit the conclusion they have arrived at with regard to a matter which they have carefully considered, and upon which evidence has been taken.

Permanent Building Necessary.

The report proceeds:

(1) The matter to which we refer is the housing of the University of London.

(2) It has become clear to us as our enquiry has proceeded that the inception of any scheme for the reorganisation of the University which we may be able to recommend to your Majesty, and which Parliament may sanction, will be seriously delayed after that sanction is obtained unless steps have previously been taken to provide for the University as reconstituted a site and buildings more convenient and adequate than those it now occupies.

(3) We think that, whatever its future constitution may be, it is a matter of national importance that the University of London should be recognised and accepted as a great public institution. In our opinion the extent and value of its work already entitle it to that position; and we are sure that the work which will rightly fall to it, as it increasingly fulfils its purposes in the future, will more and more entitle it to public recognition and support.

(4) We think it is fitting and right, and will be universally accepted, that such an institution should have for its headquarters permanent buildings, appropriate in design to its dignity and importance, adequate in extent and specially constructed for its purposes, situated conveniently for the work it has to do,

bearing its name and under its own control.

Inadequacy of Present Buildings.

(5) The evidence before us shows that the premises now occupied by the University in the Imperial Institute Buildings at South Kensington do not fulfil all these conditions, and could not be made to do so. The site of the Imperial Institute is not sufficiently central for the University. It lies on the western side of the circumference of a circle which embraces most of the University Institutions of importance, and we have had evidence that its remoteness has occasioned much inconvenience and loss of time to those who are concerned with the working of the University, and has exercised a harmful effect on its development. The buildings are shared with the Imperial Institute and are known by that name, and they have never become associated with the University in the minds of the public. The care of the fabric is in the hands of your Majesty's Office of Works, so that the University is not master in its own house.

(6) With regard to the accommodation provided, we have taken evidence, and have visited and inspected the buildings. We are satisfied that the accommodation is insufficient in extent and in many respects unsuitable for the purposes for which it is used. We are not prepared, at present, to make recommendations with regard to all the purposes for which accommodation should be provided in the central buildings of a reconstituted University. Some University purposes would be better provided for elsewhere. Such provision, for instance, as will be required for central examinations—examination halls, laboratories, waiting-rooms, and other accommodation—would be much more economically made by selecting an accessible site in a less costly position than that which will be necessary for the headquarters of the University.

A Great Hall Required.

(7) But about some things there can be no doubt. A great hall will be required for University ceremonies and for the many important occasions—such as the meetings of International Congresses and other great educational gatherings—when it is fitting that the University should act as host. The McEwan Hall in Edinburgh and the Whitworth Hall in Manchester are worthy of the Universities to which they belong, and even in so comparatively small a town as Reading a spacious hall for the academic assemblies was built in 1906. But for the University of London, founded in 1836, the only accommodation of the kind at present available is a temporary wooden structure erected in 1887 for the opening of the Imperial Institute by her Majesty Queen Victoria. It appears to us totally unfit for the uses it has to serve.

(8) Proper accommodation must clearly be provided for the Senate, for committees, for the principal, and for the headquarters staff.

(9) It is also, in our opinion, of great importance that suitable accommodation should be provided for the meetings of Convocation and for its officers. The University ought to be able to rely confidently on the sympathetic interest of its graduates in all that concerns its well-being, but, in a city as great as London is, this interest is apt to be dissipated and lost unless it is given a centre in which it can be focussed and find ex-

pression. We therefore consider that the graduates of the University should have a place of their own within the University walls.

(10) Further, we think it is a matter of great importance that accommodation—which is entirely wanting at present—should be available for developing the social and corporate life of the University. A club-house for the Union Societies, headquarters for the Officers' Training Corps, rooms for professors, graduates, and students are required in the central buildings of a University whose colleges and schools are widely dispersed.

(11) We are not yet prepared to make final recommendations with regard to the scope and purposes of the library of the University, as distinct from those in its constituent institutions and from the large public libraries of London, but we think it is clear that the University should house within its central buildings certain collections of books, and that convenient reading-rooms will be required for those who are engaged in particular researches. We therefore recommend that provision should be made at headquarters for library accommodation.

Laboratories and Lecture Halls.

(12) It has been urged upon us that provision should also be made at or near the headquarters of the University for laboratories for advanced work in a number of departments of science, which are either beyond the scope of the teaching institutions connected with the University, or for which it is thought supplementary provision ought to be made by the University itself; and, further, that lecture halls should be available for central University lectures. We are of opinion that several, though not a large number, of commodious lecture halls should be provided in the central buildings to be first erected, but the other question referred to in this paragraph is so intimately connected with the whole scheme of the reorganisation of the University that it is impossible for us to say anything about it without entering upon subjects which would carry us beyond the limits of this report. We think, however, that the purposes for which central accommodation would be useful and desirable, if it can be provided, are so extensive and varied that it would be greatly to the advantage of the University if a site could be secured of sufficient size to allow a large measure of freedom in determining the nature of the buildings to be erected, including such scientific institutes as have been referred to, if they should be found to be necessary or desirable. Indeed, the early acquisition of a site is particularly urgent, because the amount of available land in the central parts of London is always limited, and if any opportunity of obtaining a suitable site which may happen to arise should be missed, many years might elapse before such an opportunity occurred again. It is this consideration which has led us to the conclusion that we should report immediately upon this matter.

The Question of Site.

(13) Generally, and in conclusion, we think it is in the public interest, as well as in the interest of the University of London, that as large a site as possible should be obtained in a central position, and buildings erected for a reconstituted University which would be the visible sign of its recognition and acceptance as a great public institution. A great University is not self-supporting, and can

ORGAN IN ST. ANDREW'S HALL, GLASGOW. A. B. MACDONALD, ARCHITECT.

never be so. As an institution for learning in which liberal education, instruction in the methods of advancing knowledge in a wide range of subjects, and the highest professional training are combined with large scope for the free exercise of thought and with full opportunity and encouragement for the systematic prosecution of research, it can never exist financially on the fees of its students. The University of London is entitled to, and already receives, public contributions from Imperial and local funds, and your Majesty's Government has also been responsible for the housing of it throughout its history. But far more is needed than the minimum accommodation and maintenance required by the University for carrying on its routine work, and the University of London, like other Universities in this country, must depend to a large extent for the liberal support necessary for its full development upon the endowments of private benefactors. We think such benefactors are to be found if a purpose is presented to them which approves itself to their minds as honourable and useful in a high degree, and our enquiry has impressed us so forcibly with the almost unlimited possibilities of the University of London in the future, that we cannot easily conceive a more splendid opportunity than its endowment and the provision of a noble and suitable building for its home afford for the liberality of the citizen.

The report is signed as follows:—
Haldane of Cloan (chairman), Milner, Robert Romer, Robert L. Morant, L. Currie, W. S. McCormick, E. B. Sargent, Louise Creighton, and John Kemp and H. Frank Heath, joint secretaries.

NEW COUNCIL OFFICES, NEWBURN-ON-TYNE. EDWARD CRATNEY, ARCHITECT.

NEW COUNCIL OFFICE, NEWBURN.

In this issue we publish exterior and interior views of this building, which has been executed under the supervision of Mr. Edward Cratney, architect, 88, Station Road, Wallsend-on-Tyne, whose designs were placed first in an open competition, and illustrated in this paper on October 6th, 1909. The whole of the external facings are in 2½ in. hand-made red sand stocks, from Messrs. Wray and Sons, of York. The roofs are covered with Til-

berthwaite green slates, second quality of rough texture; and the stonework throughout is entirely from the Denwick quarries, Northumberland.

The general contractor was Mr. Thos. Clements, Jesmond, Newcastle; stone carving by Mr. T. Hughes, Newcastle; plumbing and sanitary work, lead rain-water pipes and heads by Messrs. R. Allison and Sons, Gateshead; heating, wrought iron balustrading and gates, by Messrs. Emley and Sons, Ltd., Newcastle;

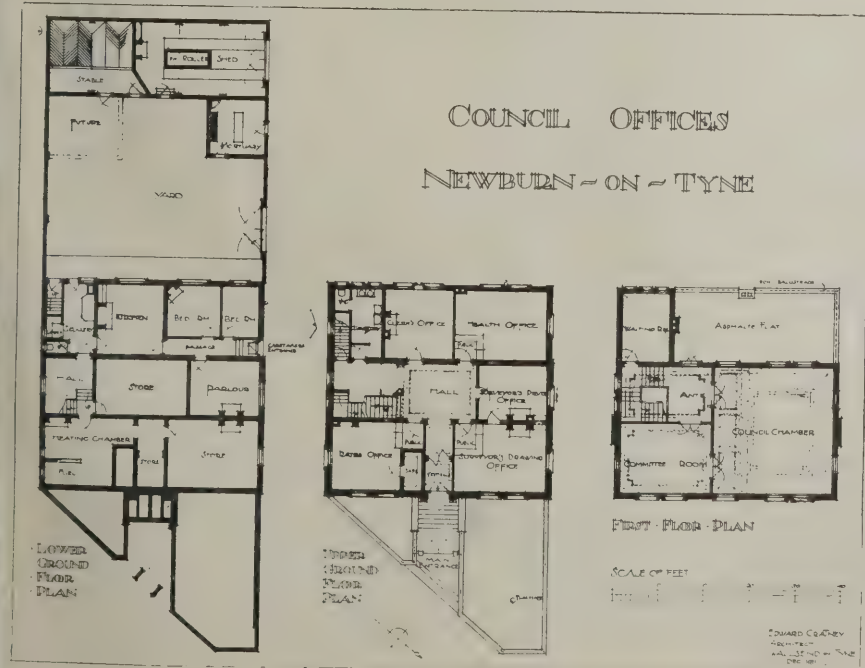

electric lighting by Messrs. Robson and Coleman, Newcastle. The plaster decorations were modelled and executed by Mr. John Ferguson, Newcastle-on-Tyne. The terrazzo flooring is by Messrs. Emley and Sons, Newcastle; and all the interior oak woodwork to the council chamber and committee-room, and the furnishings throughout, are by Messrs. Robson and Sons, Ltd., Newcastle. The whole of the interior walls and ceilings were treated with Hall's distemper.

OUR PLATE.

Organ in St. Andrew's Hall, Glasgow.

The subject of our Centre Plate this week is the organ in St. Andrew's Hall, Glasgow. The case is a noble and eminently satisfactory conception based on Classic lines. It was erected by Messrs. James Morrison and Sons, of Polmadie, Glasgow, to the design of Mr. A. B. Macdonald, City Engineer. The wood used in its construction is oak, and the approximate dimensions are: Width 75 ft., height 40 ft., depth 20 ft. There are no speaking pipes in front, an omission to be deplored from the standpoint of the purist in design. Unfortunately, it is not always possible or convenient to dispose satisfactorily of speaking pipes in the front of an organ.

Organ-case design is a subject worthy of far more attention than it usually receives. There is no reason why an organ should not form part of a decorative scheme in buildings which call for such treatment. If architects in particular would give more consideration to the requirements and limitations of organ

construction, they would soon realise how very necessary it is to leave ample head-room and space for planting the pipes.

The instrument in St. Andrew's Hall, Glasgow, is a four-manual and pedal organ, having 106 draw knobs, inclusive of couplers, which are distributed over the various departments. It has three-balanced *crescendo* pedals, one each to swell and solo organs and one over the entire organ. Tonally magnificent, it represents a remarkable achievement in organ building. It was built by Messrs. Lewis and Co., Ltd., of Ferndale Road, Brixton, who have been responsible for the design and erection of many large organs all over the country.

COMPETITIONS.

The Manchester Infirmary Site Problem.

The discussion on the utilisation of the Infirmary site was resumed at the meeting of the Manchester Junior City Council last week. Councillor Derwent Simpson, a member of the Infirmary Site Committee of the Corporation, took part in the debate. Arguing that there is no divorce between the æsthetic and the utilitarian, he stated that the Infirmary Site Committee of the City Council had kept that ideal before them, and proceeded to demonstrate how, in his opinion, they had succeeded so far as the matter now stood. After six years' study of the question he was still of opinion that the only solution was that which the com-

mittee aforesaid had recommended. He then gave figures which showed that only about thirty per cent. of the pictures comprising the permanent collection can be exhibited at the Mosley Street Gallery, while large numbers of objects of art, all well chosen and most of them gifts to the citizens of Manchester—examples of sculpture, embroidery, textiles, and reproductions by various methods of pictures—are either stowed away (often in most unsuitable places) or scattered about in most haphazard fashion. As for the Reference Library, his advice was for those who cared to be convinced of its unsatisfactory state to go and see, not merely the large reading room, but the smaller rooms, where accommodation is at present exceedingly deficient for special classes of books applicable to sections of industry in the district.

Councillor Alexander Porter said that the disposal of the present Exchange was a factor altogether ignored, and as regarded the proposed new one, hardly a member in the senior body had dared to speak of the scheme from the commercial point of view, but rather as the lesser of two evils. Some speakers that evening had talked very lightly of the transfer of the Exchange to Piccadilly, but he thought it no consolation to owners and traders in the vicinity of the present building that rateable values, rentals, etc., in the new centre would be equally profitable to other persons at that new centre.

Several other members took part in the discussion, which was again adjourned, and apparently we are not much nearer

to a decision on the dependent question of what is to be done with regard to the Libraries and Art Gallery for which the recent competition was held.

New Parliament Buildings, Winnipeg.

The High Commissioner for Canada (17, Victoria Street, London, S.W.) has received from the Minister of Public Works for Manitoba seventy-five copies of the conditions of the competition for the above new buildings. Architects can obtain copies on application.

The Halifax Town Planning Competition.

Eight sets of plans have been submitted for the town planning competition at Halifax, in which Mr. J. H. Whitley, M.P., offered awards amounting to £150. Professor Adshead, of the Department of Civic Design, Liverpool University will visit Halifax shortly to go over the areas concerned, and afterwards will consider the merits of the various plans.

King Edward Memorial at Holyrood.

The Executive Committee appointed in connection with the King Edward Memorial at Holyrood met on December 26th in the Council Chamber, Edinburgh. Lord Provost Brown presiding over a fairly large attendance of members. It was resolved to invite competitive design for the memorial at a cost of £15,000. Subscriptions have already been received amounting to more than £12,000, and it is expected that a sum of £15,000 will be realised. Should that sum be exceeded it will be possible to enlarge the scope

NEW COUNCIL OFFICES, NEWBURN-ON-TYNE: THE COUNCIL CHAMBER. EDWARD CRATNEY, ARCHITECT

NEW COUNCIL OFFICES, NEWBURN-ON-TYNE: DETAIL OF CEILING DECORATION
IN COUNCIL CHAMBER.

of the memorial, but meantime the aim of the Executive Committee is £15,000. It was further decided to invite seven architects to submit designs—three in Edinburgh, two in Glasgow, one in Aberdeen, and one in Inverness—but as it was not definitely known whether all would agree to act, the names were meanwhile withheld. It was considered that a fair representation of Scottish architects would be thus able to submit designs, and a sum of £50 is to be awarded to each sending in plans. A period of about three months will be allowed for the preparation of the plans, and on their receipt the committee will, with the help of an assessor who is yet to be appointed, go over the list and make a selection, which would be subject to the approval of the King.

LIST OF COMPETITIONS OPEN.

JANUARY 6TH, 1912. PUBLIC LIBRARY, STAFFORD.—The actual building is not to cost more than £4,000. Enquiries were to be sent to the Town Clerk, Stafford, not later than November 25th, and designs must be sent in by January 6th. The Borough Engineer states that applicants for particulars should have enclosed £1 deposit. Mr. Henry T. Hare, F.R.I.B.A., is assessor.

JANUARY 6TH, 1912. CENTRAL HALL, OFFICES, AND CARETAKER'S HOUSE, BOLTON.—The Lancashire and Cheshire Miners' Federation invite architects in practice on their own account within a radius of 25 miles of the Town Hall, Bolton, to submit designs in competition for the above. The Committee of the Federation have appointed as assessor Mr. Jonathan Simpson, F.R.I.B.A., of Bolton. The premiums offered are £50 and £25 for the two best designs in order of merit as adjudged by the assessor. Conditions and instructions will be sent to architects on application to Messrs. Fielding and Fernihough, Solicitors, 7, Fold Street, Bolton, accompanied by a deposit of one guinea (which is returnable on fulfilment of conditions).

JANUARY 8TH, 1912. WORKMEN'S DWELLINGS, BANBURY.—The Town Council of Banbury invite designs for workmen's dwellings. Applications for particulars (to be accompanied by a deposit of 10s., returnable on usual terms) to be sent not later than January 8th to Arthur Stockton, Town Clerk, Town Hall, Banbury.

JANUARY 8TH—MARCH 15TH. TOWN PLANNING, PRESTATYN.—Designs for laying-out the Prestatyn Estate are invited. Premiums of £50, £30, and £20. Application (with 10s. 6d. deposit, returnable) to be sent by January 8th to Lord

Aberconway and the Trustees of the Prestatyn Estate, 33, Henrietta Street, Strand, W.C. Designs by March 15th. Judge, Mr. H. V. Lanchester, F.R.I.B.A.

JANUARY 9TH, 1912. PUBLIC HALL, SPENNYMOOR.—Competitive designs are invited by the Spennymoor U.D.C. for a public hall, market, and offices. Premiums, £50, £25, and £10, first premium to merge in commission. Particulars (deposit £2 2s., returnable on usual conditions) from F. Badcock, Clerk to the Council, 3, James Street, Spennymoor.

JANUARY 9TH. TECHNICAL SCHOOL, MAGHERAFELT.—The Magherafelt Technical Instruction Committee invite competitive designs for a technical school proposed to be erected in Magherafelt, the total expenditure, including provision of sewerage and water supply, not to exceed £1,200. The successful competitor will supervise work and be paid a commission of 5 per cent. on the building contract sum. Designs, bearing only a nom de plume, and accompanied by a sealed envelope containing competitor's name and address, to be delivered on or before 9th January, 1912, to William D. Cousins, County Technical Office, Courthouse, Coleraine.

JANUARY 20TH, 1912. STATUE AT HAVANA.—Competition instituted by the Cuban Government for the erection at Havana of an equestrian statue of the Cuban General Maceo. Plaster models should be sent by sculptors desirous of competing to the "Comisión Ejecutiva, Monumento al General Antonio Maceo, Secretaria (de Instrucción) Pública y Bellas Artes," Havana, before January 20th. The sum of 100,000 pesos (about £20,600) has been voted for the work. British sculptors proposing to compete should first put themselves into communication with the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, E.C., where also further particulars (in Spanish) may be seen.

JANUARY 29TH, 1912. GOVERNMENT PALACE, MONTEVIDEO.—Designs are invited for a Government Palace and a town

NEW COUNCIL OFFICES, NEWBURN-ON-TYNE: ENTRANCE HALL AND
STAIRCASE. EDWARD CRATNEY, ARCHITECT.

improvement scheme. Premiums: For the former, £2,125 and £850; for the latter, £1,060, £640, and £425. Conditions, etc., at the Board of Trade, 73, Basinghall Street, E.C.

JANUARY 31ST, 1912. FEDERAL CAPITAL CITY, AUSTRALIA.—Competitive designs are invited by the Commonwealth of Australia for the laying-out of the Federal Capital City. Premiums are offered as follows: 1st, £1,750; 2nd, £750; 3rd, £500. Conditions, together with particulars, plans, and instructions, may be obtained at the office of the High Commissioner for Australia, London. Designs must be delivered by January 31st, 1912, to King O'Malley, Minister of State for Home Affairs, Commonwealth of Australia.

[The Institute of Architects of New South Wales and the R.I.B.A. have asked members and Licentiates not to take part in this competition unless the conditions are made more satisfactory. See our issue for November 8th, p. 485, and article printed in the issue of November 22nd, p. 537.]

FEBRUARY 17TH, 1912. NEW OFFICES FOR THE PORT OF LONDON.—The Port of London Authority invite preliminary sketch designs for new head offices in Trinity Square, and for lay-out of a building site. Sir Aston Webb, R.A., is the assessor.

MARCH 16TH. PUBLIC OFFICES, HARROW.—Harrow-on-the-Hill Urban District Council invite designs for enlargement and alterations of their public offices, at a cost not to exceed £4,500. Premiums, thirty, twenty, and fifteen guineas. Plan and instructions (£1, returnable) from Mr. J. Percy Bennetts, Engineer and Surveyor to the Council, Council Offices, Harrow-on-the-Hill. R.I.B.A. will be asked to appoint an assessor.

OBITUARY.

Mr. Gilbert Wood.

We regret to announce the death of Mr. Gilbert Wood, which occurred on December 22nd. Mr. Wood, who was born on April 20th, 1833, was the proprietor of "The Architect," from the active management of which journal he was compelled to retire ten years ago in consequence of a severe heart attack. From his earliest youth the late Mr. Wood was intimately connected with printing, publishing, and journalism, and he was associated during his life with a number of successful newspaper enterprises. In politics he was an ardent Conservative, his services to that party having been so distinguished that the late Lord Beaconsfield offered him a knighthood and a safe seat in Parliament, both of which, however, were declined. He was an elder of the English Presbyterian Church, and performed much useful work for the Sunday School Union.

Dr. Walter Copland Perry.

Dr. Perry, who died on Thursday last at the advanced age of ninety-seven, had made substantial contributions towards the study of classical archaeology, and had written a great deal on Greek and Roman art. He supplied the South Kensington Museum with a large collection of casts from antique statues, which, to his annoyance, were afterwards removed to Bloomsbury.

Mr. Joseph Bell.

Mr. Joseph Bell, who died at Saffron Walden last Saturday, was senior partner in the firm of Messrs. William Bell and Sons, builders, contractors, and timber merchants, of Saffron Walden and Cambridge. He was founder and a director

of Messrs. Stanton and Co., Ltd., contractors and timber merchants, King's Lynn, and one of the founders of the Meldreth Cement Company, Cambridge. He was president of the Cambridge and District Master Builders' Association, and J.P. for the County of Essex and the Borough of Saffron Walden.

Sir George Pringle.

Sir George Pringle, who died at 38, Holmbush Road, Putney Hill, on Christmas Day, at the age of 86, was called to the Bar by the Middle Temple in 1853, and was appointed assistant secretary to the Ecclesiastical Commissioners three years later. In 1872 he became secretary and steward of manors to the same board, a position which he held until 1888, when he was succeeded by the late Sir Alfred de Bock Porter. He was knighted in 1882.

Mr. Albert Edward King.

The death occurred last week of Mr. Albert Edward King, for some years an architect and surveyor, in Banter Gate, Loughborough. Mr. King, who was about 41 years of age, was a native of Yorkshire. He was articled with Mr. T. Thorpe, of Goole, and after gaining experience in other towns was for a time at Long Eaton, whence he went to Loughborough in 1897. He lived of late at his London offices, Victoria Street, Westminster, and had secured an extensive practice, principally in factory work, and in recent years with electric theatres. Mr. King had been in indifferent health for a few weeks past, and had an attack of ptomaine poisoning with pneumonia. He became seriously ill about December 15th, and in spite of the best medical skill and attention passed away on December 26th.

AUTOMATIC FIRE EXTINCTION.

Another example of the efficiency and utility of the Grinnell Sprinkler and Fire Alarm has been afforded by the fire which occurred on December 6th at Gilcomston Mills, Aberdeen. A fire originated in the exhaust house of Husk Mill. There was an installation of sprinklers throughout the mills, and ten of them were immediately put in operation by the outbreak. The alarm gong was also automatically set ringing. The protection given by the sprinkler installation was such that very trifling damage was caused by the outbreak, and the owners of the mill, Messrs. John Strachan and Sons, have written to Messrs. Mather and Platt stating that their "high opinion of the Grinnell system has been further strengthened by this practical demonstration of its reliability and efficiency." The record of the Grinnell Sprinkler at the present time is over 13,000 fires extinguished, with an average damage (including both fire and water) of only about £60 per fire. There are installations in almost every class of building where the risk of fire is more or less pronounced—textile, wood-working, boot and shoe factories, corn mills, oil mills, theatres, retail shops and stores, etc. The system is well adapted for the protection of every class of manufacturing and warehouse property.

The Infectious Hospital, Newark, is being supplied with Shorland's warm-air ventilating patent Manchester grates, patent exhaust roof ventilators and inlet ventilators, by Messrs. E. H. Shorland and Brother, Ltd., of Failsforth, Manchester.

NEW COUNCIL OFFICES, NEWBURN-ON-TYNE: FIRST-FLOOR LANDING, LEADING TO COUNCIL CHAMBER. EDWARD CRATNEY, ARCHITECT.

R.I.B.A. AUTUMN EXAMINATIONS.

Preliminary.

The Preliminary Examination, qualifying for registration as *Probationer R.I.B.A.*, was held in London and the provincial centres mentioned below on November 20th and 21st last. The Board of Architectural Education, reporting the results to the Council, state that of the 95 candidates admitted, 37 were exempted from sitting, and the remaining 58 were examined, with the following results:—

Centre.	Total Examined.	Passed.	Rele- gated.
London ..	40	27	13
Bristol ..	7	6	1
Leeds ..	3	2	1
Manchester ..	6	5	1
Newcastle ..	2	2	0
	58	42	16

The passed candidates, with those exempted, making a total altogether of 79, have been registered as Probationers, and are as follows:—

ALLUM, S. C., Paddington, W.
ANDREW, H., Hull.
ATKIN-BERRY, H. G., London, E.C.
BARLEY, F., Westcliff-on-Sea.
BARLOW, S., Stockport.
BISIKER, A. M., Crouch End, N.
BLACKPOOL, J., Kidderminster.
BOWMAN, A. W., London, S.W.
BRADSHAW, G., Failssworth, Manchester.
BRADSHAW, H. C., Wavertree, Liverpool.
BRINKWORTH, E. A., Corsham, Wilts.
BROOKS, C. J., London, S.W.
BRUETON, B. F., Bridgwater.
BURGORD, J., Holt, Norfolk.
CALDWELL, W., Penzance.
CAMERON, A. G., Inverness.
CARRERAS, L. E., St. John's Wood, N.W.
COOPER, C. M., Regent's Park, N.W.
COOPER, J. G., Willesden Green.
CROSSLEY, G., Bradford.
CROWTHER, J. H., Elland.
CURTIS, H. L., Tufnell Park, N.
DANGERFIELD, St. Albans.
DREW, S. T., Grove Park, Kent.
EVANS, F. H., Moseley, Birmingham.
FEIRN, J. L., Windermere.
FORBES, W. A. S., Newlyn.
FOSTER, K. G., Buckfastleigh.
FRAME, R., Larkhall.
GOSSLING, H. F., South Croydon.
GRAY, A., Hertford.
GUTTERIDGE, R. H., Russell Square, W.C.
HARRIS, W. H., Stoke Newington, N.
HARRISON, H. St. J., Jesmond.
HITCH, J. O. B., Vauxhall, S.W.
HUNT, R., Oxford.
HUSTLER, Colonel B., Castleford.
JACKSON, R. D., Oxtou.
JACOB, J. H., Salisbury.
JEFFREYS, H. M., Maldon, Essex.
JEYNES, H. J., Birmingham.
JOHNSON, C. MacA., C. Gloucester.
JOHNSON, H. A., Heaton Moore.
KEY, W. D., Upminster.
LANGDELL, G. A., London, S.W.
MACBEAN, I. B., Ealing Common, W.
MACPHERSON, H., Langside, Glasgow.
MARNER, G. L. S., London, E.C.
MARTYN, E. A. L., Redruth.
MERCER, J. F. L., Blackburn.
MILNES, F., Huddersfield.
MOERDIJK, G., Battersea Park, S.W.
MOSLEY, A. R., Eastbourne.
OMAR, J., Hampstead, N.W.
PALMER, A. J., London, N.W.
PAUL, H., Junr., Ealing, W.
PITE, R. W., Ealing, W.
POWELL, F. H., Bournemouth.
PYE, J. F., Grimsby.
REMEDIOS, R. M., dos, Maida Vale, W.

RIX, A. D., Norwich.
ROBINSON, J. J., Kentish Town, N.W.
ROGERS, J. R., Leamington Spa.
ROUTLEY, L. J., Taunton.
RUDMAN, W., Chippenham.
SHACKLETON, F. H., Luton.
SHIBLEY, A. R., Merton Park, Surrey.
SMITH, C. H. N., Norfolk.
SPURWAY, G. V., Milverton.
STANLEY, L. S., Cambridge.
TANNER, E. A. D., Fulham, S.W.
THOMAS, D. R., Llangadock.
THOMAS, H. M., Maidstone.
THOMSON, J. S., Wimbledon, S.W.
TUNNARD, H. B., Denmark Hill, S.E.
WAGER, F., Aston Cross, Birmingham.
WALKER, S. E., Halifax.
WILLIAMS, L. E., Stockwell, S.W.
WILLIAMS, P. J., Carmarthen.

Intermediate.

The Intermediate Examination, qualifying for registration as *Student R.I.B.A.*, was held in London and the undermentioned provincial centres on November 20th, 21st, 23rd, and 24th. The Board of Architectural Education report to the Council that 100 candidates were admitted and examined, with the following results:—

Centre.	Total Examined.	Passed.	Rele- gated.
London ..	59	36	23
Bristol ..	8	5	3
Leeds ..	5	2	3
Manchester ..	23	14	9
Newcastle ..	5	3	2
	100	60	40

The successful candidates, who have been registered as Students, are as follows, their names being given in order of merit as placed by the Examiners:—

BENNETT, T. P., Kilburn, N.W.
THOMAS, W. N., Crewe.
NEWTON, W. G., London, W.
LORNE, F., London, W.C.
HOFER, M. R., Eastcote, Middlesex.
ROBERTSON, M. D., London, W.C.
MACKENZIE, K. B., London, W.C.
DUBINS, L. G. A., London, S.W.
WOODROFFE, N. F., Purley Downs, Surrey.
ROWNTREE, C., Hammersmith, W.
LAIT, L. H., Ravenscourt Park, W.
EBBS, E. H. M., Harlesden, N.W.
HINTON, J. G., Winchester.
WALTER, R. A., Harringay, N.
ELGAR, W. H., Folkestone.
FRISCOTT, H. S., Plymouth.
MOERDIJK, G., Battersea Park, S.W.
TAYLOR, R. V., Southport.
WILLIAMSON, F., Levenshulme.
GOLD, H. A., Beckenham, Kent.
HARLAND, N. G., Stamford Hill, N.
HILL, C. E., Sheffield.
CHEADLE, J. O., Kensington, W.
HART, E. J., Salford.
PIDSLEY, W. G., Pinhoe, Devon.
RUDHALL, P. W. G., London, N.W.
HEMM, G., Heaton Chapel, near Stockport.
ROBERTSON, G. A. K., Belfast.
CLARK, C. J. K., Newcastle-on-Tyne.
BOTHWELL, E. F., Forest Gate, Essex.
BROADHEAD, F. A., Nottingham.
CLARK, S., Carlisle.
EDWARDS, A. T., Liverpool.
GARRETT, S. C., Brighton.
GRICE, W. S., Ealing, W.
HARWOOD, A. W., Pall Mall East, S.W.
JACKSON, B. de C., Beckenham.
LEWIS, W. J., Pontypridd.
MADDOCK, R. H., Sutton, Surrey.
MATTHEWS, R. E., Coventry.
MCLEAN, G., Portmadoc.
MOUNTFORD, E. W., Guildford.
NICHOLS, C. E., Eckington, Sheffield.

NORRIS, E. B., Didsbury.
PALMER, J., Islington, N.
PARKIN, W. G., Hampstead, N.W.
RILEY, R. H., Lower Darwen.
SILCOCK, A., Bath.
SMITH, T. H., Bolton.
SUNTER, M. C., C-on-M. Manchester.
TOONE, A. A. G., Chorlton-cum-Hardy, Manchester.
WEST, A. J., Nottingham.
WHITE, P. G., Bickley, Kent.
WIGGINS, J. S., Brighton.
WILLIAMS, J. G., St. John's Wood, N.W.
WILLIAMS, W. J. V., Llansamlet, Swansea.
WILSDON, P. T., West Kensington, S.W.
WINDER, A. M., Oldham.
WOODHOUSE, B. W., Carlisle.
YETTS, L. M., B.A., Finsbury Pavement, E.C.

The following table shows the number of failures in each subject of the Intermediate Examination:—

I. Classic Architecture ..	18
II. Mediæval Architecture ..	27
III. Renaissance Architecture ..	34
IV. General Questions ..	20
V. Theoretical Construction ..	18
VI. Descriptive Geometry ..	20
VII. Applied Construction ..	17

Intermediate Exemptions.

The following candidates, having produced, in accordance with the regulations, satisfactory evidence of previous training, were exempted from sitting for the Intermediate Examination, and have been registered as Students R.I.B.A.—namely:—

BARRY, F. R., jun., Kew Road, Richmond, Surrey [Architectural Association School].
CARRERAS, L. E., St. John's Wood, N.W. [Division of Architecture, King's College].
HUGHES, V. H., Sandgate, Kent [School of Architecture, Liverpool University].
OMAR, I., Hampstead, N.W. [School of Architecture, University College].
WEBB, P. E., Ladbroke Square, W. [Architectural Assoc. School].
WILLIAMS, L. E., Stockwell, S.W. [Division of Architecture, King's College].

Final and Special.

The Final and Special Examinations qualifying for candidature as Associate R.I.B.A. were held in London from November 30th to December 8th. The Board of Architectural Education report to the Council that of the 99 candidates admitted and examined, 56 passed and the remaining 43 were relegated to their studies. The passed candidates, who, subject to Clause 8 of the Charter, have become qualified for candidature, are as follows, the * prefixed to a name indicating that the candidate sat for the Special Examination, which is designed for architects in practice and chief assistants exempted by the Council from the Preliminary and Intermediate Examinations and from submitting Testimonies of Study:—

ARCHER, H. H., Windsor.
BAREFOOT, H. J. L., Wandsworth Common, S.W.
BARGMAN, R. F., Dorking.
*BAXTER, J. A. M., Edinburgh.
BENNETT, T., Gravesend.
BESANT, H. S., Lee, Kent.
BRITTAN, H. W., Croydon.
*CASTLOW, C., Roundhay, Leeds.
CLARKE, J. M., Fulwood, Preston.
COWDELL, C. J. M., Leicester.
CROUCH, F. A., Hove, Brighton.
*CULLEN, D. S., South Norwood.

DOVASTON, J., Ealing, W.
DOWDESWELL, F., Palmer's Green, N.
DUNN, G. M., Cheapside, E.C.
DURRANT, A. M., Hemel Hempstead.
EDWARDS, S. J., Bayswater, W.
GROUND, J. K., Bloomsbury, W.C.
HEALING, J. B., Leicester.
HEPWORTH, P. D., Hampstead Heath,
N.W.

JOHNSTON, B., South Ealing, W.
*KNEWSTUBB, J. J., Penrith.
*LARSEN, A. W., Grove Park, W.
LAY, C. H., Hampstead, N.W.
LENTON, F. J., Stamford.
LING, R. B., Clapham Common, S.W.
*LOVELL, R. G., Eastbourne.
MARTIN, H. R., Lee, S.E.
MEIKLEHAM, D. L., Golder's Green, N.W.
MORLEY, F. H., Liverpool.
MOSS, H. E., Kingston-on-Thames.
NICHOLSON, F. W., Anfield, Liverpool.
*NICOL, R. D., Calcutta, India.
ORDISH, R., Derby.
OWEN, G., London, W.C.
*OXLEY, W. B., Leicester.
PAGE, J., Barnet.

PHILLIPS, A. T., Harpenden.
ROBINSON, H. G. F., Hampstead, N.W.
RUSSELL, A. L. N., London, W.
SELWAY, E. R. D., Clapham, S.W.
SHEARS, R., Westcliff-on-Sea.
SINCLAIR, W. B., Bexley, Kent.
SOUSTER, C. L., Lee, S.E.
STEDMAN, W. B., Harlington, Middlesex.
*STEWART, H. S., Bloomsbury Square,
W.C.
STOCKTON, R., Stockport.
*SWASH, F. S., Llandrindod Wells.
VOYSEY, C., Junr., Baker Street, W.
*WELFORD, A., Bloomsbury Square, W.C.
WHITE, C. H., Bishopston, Bristol.
WHITEHEAD, T. G., Croydon, S.W.
WHYMPER, W., Gray's Inn Square, W.C.
WILLCOCKS, C. B., Caversham Heights,
Oxon.
WORTHINGTON, J. H., Alderley Edge.
*WYLD, R. S. B., Bedford Row, W.C.

The following table shows the number of failures in each subject of the Final and Special Examination:—

I. Design	31
II. The Principles of Architecture	24
III. Building Materials	11
IV. Principles of Hygiene	25
V. Specifications	18
VI. Construction—Foundations,	31
etc.	31
VII. Construction—Iron and	30
Steel, etc.	30

Ashpitel Prize, 1911.

The Board of Architectural Education recommend the Council to award the Ashpitel Prize for 1911 to Mr. Philip Dalton Hepworth [P. 1907, S. 1910] of "Cahirdown," Holford Road, Hampstead Heath, who passed the Final Examination above referred to, he being the candidate who has most highly distinguished himself in the Examinations held during the past year.

NEW ASSOCIATION OF CONSULTING ENGINEERS.

On January 15 next, at 4 p.m., in the lecture theatre of the Institution of Electrical Engineers, the inaugural meeting will be held of the Association of Consulting Engineers, the formation of which was decided upon at a meeting of engineers held last autumn under the presidency of Sir William Preece. On that occasion a committee was appointed to draw up rules, and a copy of these has

been sent to us by Mr. A. H. Dykes, the honorary secretary.

It is provided that there shall be one class of member only, who must fulfil the following conditions: (a) He shall be in practice as a consulting engineer, either individually or as a partner of a firm of consulting engineers; (b) shall be of such standing as, in the opinion of the committee of the association, entitles him to admission to the association; (c) shall be a full member of the institution representing the particular branch of the profession in which he practises; (d) shall not be a member of, or a partner in, or an agent for, any contracting or manufacturing firm or company or business with which he may have occasion to deal on behalf of his clients; (e) shall not be a director or employee of, or be an agent for, any company doing engineering insurance work; and (f) shall not be connected with any company or business who advertise or canvass for consulting work.

The rules which relate to the conduct of members are as follows: (1) A member shall act in all professional matters strictly in a fiduciary capacity with regard to any clients whom he may advise, and his charges to such clients shall constitute his only remuneration in connection with such work. (2) He shall not accept any trade commissions, discounts, allowances, or any indirect profit in connection with any professional work on which he is engaged. (3) He shall not, without disclosing the fact in writing to his clients, be a director of, or shareholder in, or have a financial interest in, any contracting or manufacturing firm or company or business with which he may have occasion to deal on behalf of his clients. (4) He shall not receive directly or indirectly any royalty, gratuity, or commission on any patented or protected article or process and on work which he is carrying out for his clients unless and until such royalty, gratuity, or commission has been authorised in writing by those clients. (5) He shall not act for a new client to the prejudice of an existing client. (6) He shall place orders explicitly on behalf of his client and not on his own behalf. (7) Except at the request of the client he shall not be the medium of payments to any contractor or business firm, but shall only issue certificates for payment by his client. (8) He shall not knowingly accept professional work in connection with which another member has been appointed, unless either formally notified by the client of the termination of the previous appointment or else in collaboration with the other member. (9) He shall not advertise directly or indirectly for professional employment, nor shall he answer any advertisement for a consulting engineer. (10) He shall not solicit professional work either directly or indirectly or by an agent, nor shall he pay by commission or otherwise any person who may introduce clients to him. (11) He shall not conduct himself in a manner, nor act in any capacity, nor hold any appointment, which, in the opinion of the committee of the association, prejudices his position as a consulting engineer.

The remainder of the rules are concerned with the election and expulsion of members and with the committee and its functions.

It will be seen from the foregoing that the conditions of membership are, very properly, of a stringent character, and likely to gain for the association a high status. We wish the association success.

CORRESPONDENCE.

Architects of the Office of Works.

To the Editor of the "ARCHITECTS' AND BUILDERS' JOURNAL."

SIR,—Mr. Dudley Ward, as representing the First Commissioner, in his answer on December 15 to Mr. Noel Buxton in the House of Commons, when asked to "state the classes and the total number of architects employed in his department," and "what number of them are associates or licentiates of the Royal Institute of British Architects," makes no mention of the class, numbering forty, termed "architectural assistants," of whom nineteen are associates or licentiates.

This omission is all the more curious seeing that Mr. Dudley Ward had his attention drawn to this class very distinctly by Mr. Philip Snowden in the House of Commons as recently as November 24th, and he then stated he would consider establishments for "a number of professional men engaged in the Office of Works termed architectural assistants, who possess their Board's certificate of technical efficiency, some of them being members of the Royal Institute of British Architects, Surveyors' Institute, and allied societies." And more recent still (on December 7th), he replied to Mr. Philip Snowden in the House that "the desires of each member of the architectural assistants' class should have the opportunity of being placed upon the established list."

This list being incomplete, may we not therefore assume the cost of the staff in salaries therein stated to be 3.34 per cent. to be equally incomplete, to the extent of another 3 per cent. [bringing it into accordance with the figure mentioned by the President of the R.I.B.A.]?

"THE WHOLE TRUTH."

Wren and Hampton Court.

To the Editor of the "ARCHITECTS' AND BUILDERS' JOURNAL."

SIR,—Commenting on my paper, you wrote in your issue of the 20th ult.: "Has the former blind worship of Wren brought about at length the inevitable reaction? When, in its turn, dispraise of him has run its course, we may get the reasoned view of him." This is a further consideration to my subject, and it touches a well-established human characteristic. But my point with regard to Wren at Hampton Court was: "What the devil was he doing in that galaxy?"

The east and south fronts of Hampton Court in Tudor times were the Queen's and King's lodgings respectively, as they continued to be after Wren's rebuilding. The drawings of Wynegaerde show that these were the principal and not the least picturesque parts of the building. For the sake of rebuilding in the new fashion Wren was instructed to destroy the best of that which was old; and, as we know, the intention was to have replaced much more of the building. What remains of the Tudor work one values, and what Wren built one also admires; but it would have been better to have left the old and built a new palace elsewhere. In short, it is folly to pull down one good thing to replace it with another; and this is as true of buildings as you have pointed out it is of the reputations of their builders.

CLOUDESLEY S. WILLIS.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

The Concrete Institute.

The third volume of "Transactions and Notes" of the Concrete Institute, consisting of

328 pages, and containing many illustrations and several folding plates, affords substantial proof of the value and success of the Institute, which having been in existence for more than two years, may now be assumed to have become firmly established. It was of course quite impossible that the Institute should have sprung from the head of Minerva fully armed and finally equipped for all contingencies, and therefore it is not surprising to find in this volume a record of progressive change. The most important modification is that which may be said to affect the constitution of the Institute. At first there were a Council and an Executive. The general nature of their respective functions is sufficiently indicated in their titles; and, theoretically, it no doubt seemed, at the outset, to be right and proper to have a deliberative body, and an administrative committee to which its powers could be delegated. Where possible, however, the simplification of any sort of machinery is always desirable; and there can be little doubt of the wisdom of deciding to consolidate the management of the Institute's affairs by passing new rules to the effect that the council shall not only have the responsibility, but also the actual management, to its credit—an arrangement that, with other institutions, has been found sufficiently satisfactory, as minimising the obvious risks of delay, misunderstanding, and possible friction.

Educational Facilities.

At the same time that this new rule was passed another was introduced, and also passed, having

for its object the admission of students. Some surprise has been expressed that this provision was not made at the very beginning, but probably the Institute followed quite the normal course in getting itself thoroughly established, and in ascertaining in practice whether it could reasonably undertake the responsibility of entertaining students. It can, at all events, now show that it has something definite to teach, and that it is in a position to lead students into the right paths, if for the moment there is lacking the full educational equipment and organisation which later may possibly come into being. In the meantime, it may be justly said that the Institute itself is a very effective educational instrument. The Institute, however, has still very much to do by way of gathering information before it can very confidently adventure on the complementary and perhaps more responsible process of imparting it. Nevertheless, in its conferences, its lectures, its visits, and above all in the publications in which its transactions are recorded, the Institute affords very special facilities for students, among whom may be counted many others besides those who are in "the first flush of youth." With regard to the lectures, it has been complained that they are not so well attended as they should be—probably because they are necessarily somewhat narrow in scope, and of restricted interest.

Educationally, this is rather an advantage; repetition, indeed, being one of the essential conditions of the acquirement of knowledge. Repetition, however, hardly tends to popularity or attractiveness, and the lectures and discussions having apparently gone the full round of the subject—which is a very different thing from exhausting it in detail—the attendance is neither so numerous nor so representative as it should be. Not, perhaps, are the lecturers and their subjects so various as they might be, and probably will be, seeing that, in the future, engineering interests are to be included.

A Common Meeting Ground.

Some means of stimulating the interest of architects should be devised. We have repeatedly urged upon architects the desirability of availing themselves to the full of such facilities for acquiring information with regard to reinforced concrete construction as the Institute affords; but apparently the only occasions on which architects are noticeably present at the meetings are those when an architect is announced to deliver a lecture, as, for instance, when Professor Beresford Pite, F.R.I.B.A., read his paper on "The Artistic Treatment of Concrete," which is duly printed in the volume of the Institute's Transactions under notice. It will be remembered that several architects took part in the discussion of Professor Pite's paper—namely, Mr. H. Heathcote Statham, F.R.I.B.A., Mr. A. Alban H. Scott, M.S.A., Mr. A. E. Corbett, F.R.I.B.A., Mr. Percival Fraser, A.R.I.B.A., and, of course, the chairman, Sir Henry Tanner, F.R.I.B.A. A few architects of distinction are members of the Institute, but we should like to see the architectural element greatly and immediately strengthened, lest peradventure it may in course of time become swamped by engineering interests. The Institute seems to offer an excellent, and almost a unique, opportunity for architects, engineers, and concrete and cement experts, to meet on common ground, to mutual advantage.

The Architect and the Engineer.

The discussion of Professor Pite's paper afforded one slight but significant example of the benefits of face-to-face conference between various denominations of builders. The incident served at once to show how easily a misunderstanding may arise, and how easily it may be explained away when opportunity allows. An architect had said, in the course of the discussion: "I think the greatest trouble we shall have in the future in connection with the æsthetic treatment of concrete buildings will be with the so-called specialists and engineers. The engineers are designing too many buildings, and that is, I think, where we shall have the greatest trouble. Concrete building work is gradually leaving the architect's hands and getting into the purely constructional men's hands." This observation was on some hands regarded as a slight on engineers—a sense which was far from the intention of the author, as he promptly explained when one or two speakers who followed him mentioned how it had struck

them. One gentleman understood the reference to imply "that concrete will be in a bad way if it is left in the hands of the engineers," and he forthwith launched into a glorification of the Forth Bridge and the Assouan Dam. Another said: "I am afraid, Sir, I am an engineer, and I am not supposed to know much about beauty. At least, I rather gather that is the idea." An architect at once corrected this impression by remarking that the observations on engineers had been, he thought, rather misunderstood: "Nobody can say for a moment that purely engineering works are usually ill-designed—as, for instance, such works as the Forth Bridge and the Assouan Dam, which are, I think, most beautiful—but with regard to the facade of a building, I think it is somewhat outside an engineer's scope, and it is, I think, with regard to such architectural treatment that the remarks applied." That this was so was confirmed by the author of the misunderstood passage: "My reference to engineers was purely from an architectural point of view, applying to the facings of buildings and not to the magnificent engineering works which they have done." It is to be hoped that the explanation was satisfactory to the engineers. Whether or not it cleared up this particular misunderstanding quite conclusively is a matter of less importance than the illustration the incident affords of the advantages of conference: which is a point that should need no reinforcement.

The Case for Fraternity.

It was reinforced, however, and very ably, by Professor Pite in replying to the discussion on his paper: "I dispute," he said, "the right of engineers to deal æsthetically with any subject without training. They have no more right to talk about how they design masses having vertical and horizontal forms than I have any right, as an architect, to discuss with them how I am to design an enormous concrete work. If I know, I should expect them to listen to me; if they know, I should listen to them with pleasure. Why, Sir, did not the Council of this Institute invite a distinguished engineer to read a paper on 'The Æsthetic Treatment of Concrete buildings'?" The advantages of conference could hardly have been more forcibly put. Clearly, if the architect, the engineer, and the expert will only listen to each other, they will hear some useful home truths that may ultimately fructify into applications of immense practical value; and if the various denominations of builders will only fraternise more freely, there must ensue an enormous gain in understanding, confidence, and esteem.

Texture and Facing.

The subject of texture being among the topics of the moment, it may be interesting to draw attention to some observations on this subject that were made by Sir Henry Tanner in the course of the discussion on Professor Pite's paper. Sir Henry said: "It seems to me that reinforced concrete has to be considered from different standpoints. If you have it in a building in a town, it has to be treated in a different

at the centre being $\frac{2r}{3}$

The following additional values will be useful in calculations:—

a	$\frac{y_A}{r}$	$\frac{y_c}{r}$
0
0.1
0.2
0.3
0.4
0.5

For values above $a=.5$, work from the other end for $(1-a)$ and reverse y_A and y_c .

If, therefore an isolated load P be placed at the point G on the arch, project G vertically upwards to meet the intersection locus XX at J and from J draw tangents JK, JL to the reaction envelope MNO to meet the vertical through A and C at K and L .

To get the horizontal thrust H and vertical reactions V_A, V_c set down $ab = P$, Fig. 9, and draw ac parallel to JK and bc parallel to JL ; then, if cd is drawn perpendicular to ab , $cd = H$, $ad = V_A$ and $db = V_c$.

If we require the bending moment at any point Q of the arch, this is given by $B = H \times Q'S$.

Proof of Formulæ.

Take first equation—40:

From A to N , Fig. 7, $B = V_A x - H(y - y_A)$

From N to C , $B = V_A x - H(y - y_A)$

$$\therefore \int_0^1 B dx = \int_0^1 V_A x dx - \int_0^1 H(y - y_A) dx$$

$$= \int_0^1 P(x - al) dx$$

As before $y = \frac{4r}{12}(lx - x^2)$

$$\text{Now } \int_0^1 V_A x dx = \frac{V_A l^2}{2}$$

$$\int_0^1 H(y - y_A) dx = -Hy_A l + \frac{4rH}{12} \left(\frac{l^3}{2} - \frac{l^3}{3} \right)$$

$$\int_{a1}^1 P(x - al) dx = \left[P \left(\frac{x^2}{2} - alx \right) \right]_{a1}^1$$

$$= P \left(\frac{l^2}{2} - al^2 - \frac{a^2 l^2}{2} + a^2 l^2 \right)$$

$$= \frac{Pl^2}{2} (1 - 2a + a^2) = \frac{Pl^2}{2} (1 - a)^2$$

$$\therefore \int_0^1 B dx = \frac{V_A l^2}{2} - Hl \left(\frac{4r}{6} - y_A \right) - \frac{Pl^2}{2} (1 - a)^2$$

\therefore Dividing through by $\frac{1}{2}$ equation (40) becomes

$$V_A l - 2H \left(\frac{2r}{3} - y_A \right) - Pl(1 - a)^2 = 0 \quad (46)$$

These integrations and proof are given in full, because the writer does not know of a book where they are set out without the omission of most of the steps, so that many students are unable to follow the steps at all. The inclusion of the steps gives, however, an appearance of length which can hardly be avoided under the circumstances.

Next take equation (39): The values of B are as before \therefore we have

$$\int_0^1 B x dx = \int_0^1 V_A x^2 dx - \int_0^1 H(y - y_A) x dx$$

$$= \int_{a1}^1 P(x - al) x dx$$

$$\int_0^1 V_A x^2 dx = \frac{V_A l^3}{3}$$

$$\int_0^1 H(y - y_A) x dx = \frac{4rH}{12} \left(\frac{l^4}{3} - \frac{l^4}{4} \right) - Hy_A \frac{l^2}{2}$$

$$\int_{a1}^1 P(x - al) x dx = \left[P \left(\frac{x^3}{3} - alx^2 \right) \right]_{a1}^1$$

$$= P \left(\frac{l^3}{3} - \frac{al^3}{2} - \frac{a^3 l^3}{3} + \frac{a^4 l^3}{2} \right)$$

$$= \frac{Pl^3}{6} (2 - 3a + a^3) = \frac{Pl^3}{6} (1 - a)^2 (2 + a)$$

$$\therefore \int_0^1 B x dx = \frac{V_A l^3}{3} - H \left(\frac{rl^2}{3} - \frac{y_A l^2}{2} \right) - \frac{Pl^3}{6} (1 - a)^2 (2 + a)$$

\therefore Equation (39) becomes, dividing through by $\frac{l^2}{3}$

$$V_A l - H \left(r - \frac{3y_A}{2} \right) - \frac{Pl}{2} (1 - a)^2 (2 + a) = 0 \quad (47)$$

Finally take equation (38), using the same values of B :

$$\int_0^1 B y dx = \int_0^1 V_A x y dx - \int_0^1 H(y - y_A) y dx$$

$$= \int_{a1}^1 P(x - al) y dx$$

$$\int_0^1 V_A x y dx = \int_0^1 V_A \frac{4r}{12} (lx - x^2) x dx$$

$$= \frac{V_A 4r}{12} \left(\frac{l^4}{3} - \frac{l^4}{4} \right) = \frac{4V_A r l^2}{12} = \frac{V_A r l^3}{3}$$

$$\int_0^1 H(y - y_A) y dx = \int_0^1 H y^2 dx - \int_0^1 H y_A y dx$$

$$\text{1st term} = H \int_0^1 \frac{16r^2}{14} (l^2 x^2 - 2lx^3 + x^4) dx$$

$$= \frac{16r^2 H}{14} \left(\frac{l^5}{2} - \frac{2l^5}{4} + \frac{l^5}{5} \right) = \frac{8r^2 H l}{15}$$

$$\text{2nd term} = \int_0^1 H y_A \frac{4r}{12} (lx - x^2) dx$$

$$= \frac{H y_A 4r}{12} \left(\frac{l^3}{2} - \frac{l^3}{3} \right) = \frac{2r H y_A l}{3}$$

$$\int_{a1}^1 P(x - al) y dx = \int_{a1}^1 P x y dx - \int_{a1}^1 P a l y dx$$

$$= P \int_{a1}^1 \frac{4r}{12} (lx - x^2) x dx$$

$$= P a l \int_{a1}^1 \frac{4r}{12} (lx - x^2) dx$$

$$= \frac{4Pr}{12} \left[\frac{l^3}{3} - \frac{x^4}{4} \right]_{a1}^1 - \frac{P a 4r l}{12} \left[\frac{l^2}{2} - \frac{x^3}{3} \right]_{a1}^1$$

$$= \frac{4Pr}{12} \left\{ \frac{l^4}{3} - \frac{l^4}{4} - \frac{a^4 l^4}{3} + \frac{a^4 l^4}{4} \right\}$$

$$- \frac{4Pr a l}{12} \left\{ \frac{l^3}{2} - \frac{l^3}{3} - \frac{a^3 l^3}{2} + \frac{a^3 l^3}{3} \right\}$$

$$= 4Pr l^2 \left\{ \frac{1}{12} - \frac{a^3}{3} + \frac{a^4}{4} - \frac{a^3}{6} + \frac{a^3}{3} - \frac{a^4}{3} \right\}$$

$$= \frac{4Pr l^2}{12} \{ 1 - 2a + 2a^3 - a^4 \}$$

$$= \frac{Pr l^2}{3} (1 - a)^3 (1 + a)$$

\therefore Collecting together, we get:

$$\int_0^1 B y dx = \frac{V_A r l^2}{3} - \frac{8r^2 H l}{15} + \frac{2r H y_A l}{3}$$

$$- \frac{Pr l^2}{3} (1 - a)^3 (1 + a)$$

Dividing through by $\frac{rl}{3}$, equation (8) becomes:

$$V_A l - H \left(\frac{8r}{5} - 2y_A \right) - Pl(1 - a)^3 (1 + a) = 0 \quad (48)$$

FIG. 9.

Subtract equation (47) from (46) and we get:

$$H \left(\frac{r}{3} - \frac{y_A}{2} \right) = + \frac{a}{2} Pl(1 - a)^2 \quad (49)$$

Subtract equation (48) from (47), thus getting:

$$H \left(\frac{3r}{5} - \frac{y_A}{2} \right) = \frac{a}{2} (1 + 2a) Pl^2 (1 - a)^2 \quad (50)$$

Divide (49) by (50), then:

$$\frac{\frac{r}{3} - \frac{y_A}{2}}{\frac{3r}{5} - \frac{y_A}{2}} = \frac{1}{2a + 1}$$

$$\therefore - \frac{y_A}{2} (2a + 1 - 1) = \frac{3r}{5} - \frac{r}{3} (2a + 1)$$

$$- a y_A = \frac{9r - 10ar - 5r}{15}$$

$$y_A = \frac{(10a - 4)r}{15a} \text{ as in equation (44)}$$

Now put this value in equation (49), then

$$H \left\{ \frac{r}{3} - \frac{(5a - 2)r}{15a} \right\} = \frac{a}{2} Pl(1 - a)^2$$

$$\therefore Hr \left\{ \frac{5a - 5a + 2}{15a} \right\}$$

$$= \frac{2Hr}{15a} = \frac{a}{2} Pl(1 - a)^2$$

$$\therefore H = \frac{15(1 - a)^2 a^2 Pl}{4r} \text{ as in equation (43)}$$

Put these results in equation (46) and we get:

$$V_A l = \frac{15(1 - a)^2 a^2 Pl}{2r} \left(\frac{2r}{3} - \frac{(10a - 4)r}{15a} \right)$$

$$+ Pl(1 - a)^2$$

$$= Pl(1 - a)^2 \left\{ \frac{15a^2}{2r} \left(\frac{4r}{15a} \right) + 1 \right\}$$

$$= Pl(1 - a)^2 (1 + 2a) \quad (41)$$

$$V_A = P(1 - a)^2 (1 + 2a) \quad (42)$$

$\therefore V_c = P - V_A = P(3 - 2a)a^2$

Finally, a substitution in equation (37) gives:

$$y_c = \frac{(6 - 10a)r}{15(1 - a)}$$

Temperature Thrust.

For fixed or hingeless arches the temperature thrust is found in a manner similar to that used for two-hinged arches by making the horizontal movement equal to the expansion of the span.

For the parabolic girder that we have been considering if e is the coefficient of expansion the temperature thrust H_T for an increase t of temperature is given by the equation:

$$H_T = \frac{45EJ_{et}}{4r^2}$$

this acts at a height $\frac{2h}{3}$ from the base line AC .

THE CENTRAL Y.M.C.A. BUILDING.

THE NEW CENTRAL Y.M.C.A. BUILDING, TOTTENHAM COURT ROAD, LONDON. ROWLAND PLUMBE, F.R.I.B.A., ARCHITECT.

THE new central Y.M.C.A. building in Tottenham Court Road, W.C., provides one of the most recent examples of the successful and economical application of reinforced concrete as a constructional medium.

The work, which is of a somewhat monumental character, presents several very interesting features, interesting alike to architects and engineers, and an endeavour will be made to describe some of the most important features in connection with the work.

The building stands on an island site having an area of 3,175 yards super. the main entrance being in Great Russell Street, facing south-east. There are four floors, in addition to the basement and flat roof, which extends over the whole site, the fifth floor only covering a portion of the whole area. The main tower at the corner of Tottenham Court Road and Great Russell Street contains a sixth, seventh, and eighth floor, the latter being at the base of the ferro-concrete dome.

The height of the main roof above ground is about 58 ft., and the base of the dome about 106 ft.

The staircases and landings throughout the building are constructed completely in reinforced concrete.

At the Caroline Street end of the building there is a ferro-concrete retaining wall, extending along the whole length of the frontage about 148 ft., the wall being 12 ft. high from top of slab. A typical section is shown in Fig. 1. The slab under the wall is 5 in. thick only and 5 ft. wide over all; the buttresses, which are the same width as the slab at the bottom, are spaced at about 10 ft. 6 in. centres, the horizontal beam at the top of the wall being 12 in. wide by 5 in. deep. The wall itself is only 5 in. thick, and is reinforced with $\frac{1}{8}$ in. and $\frac{3}{8}$ in. diameter bars suitably spaced, the pressure from the earth being transmitted by the $\frac{3}{8}$ in. diameter bars in the wall slab to the horizontal beams U and V, which in turn transmit it to the buttresses, which act as cantilever beams from the bottom slab. In the arrangement shown in Fig. 1 a portion of the load is transferred by means of the stays X to the main ferro-concrete columns, and is consequently spread over a considerable area of ferro-concrete floor at that level. The buttresses are 7 in. thick, and are reinforced with two bars $d=1\frac{1}{2}$ in., the shear members being the usual Hennebique stirrups made out of $1\frac{1}{4}$ in. by $\frac{5}{8}$ in. steel hoop, and spaced as shown. The horizontal beams U and V have two bars, $d=1$ in. and $d=\frac{3}{4}$ in. respectively, with

$\frac{1}{8}$ in. diameter links as binders spaced at 6 in. centres, the links used being similar to those used in the columns. The stays X are reinforced with one bar $d=\frac{1}{2}$ in. top and bottom, the beams being 2 ft. 3 in. deep at the springing and 12 in. deep at the crown, the shear members at top and bottom being stirrups of $1\frac{1}{4}$ in. by $\frac{5}{8}$ in. hoop steel. The method of transferring and spreading the pressure from retaining walls over as large an area as possible is one which is easily and economically adopted where reinforced concrete is the constructional medium, owing to its exceptional monolithic nature.

The gymnasium, which is 48 ft. wide by 84 ft. long, is immediately underneath the large hall, the floor of which is supported by six large arched beams having an effective span of 50 ft. (see Fig. 2). The beams are generally 6 ft. deep at the springing and 2 ft. 2 in. deep at the crown, including the floor, and are spaced at 10 ft. 6 in. centres; the flooring is 5 in. thick, and the secondary beams are 12 ft. by 6 in. wide, spaced at 8 ft. centres.

The floor is designed to carry a load of 1 cwt. per ft. super (exclusive of weight of floor), and is reinforced in the 10 ft. 6 in. by 8 ft. panels, with carrying bars $d=\frac{5}{8}$ in. at $6\frac{1}{2}$ in. centres, straight and curved alternately, and straight top bars

$\frac{1}{4}$ in. diameter running at right angles to the carrying bar, 6 in. apart. The secondary beams, which transfer the load from the floor slabs, direct to the main arch beams, have generally four tension bars (the area depending on the span of floor carried), with $1\frac{1}{4}$ in. by $\frac{1}{8}$ in. hoop steel stirrups to take up the shear. In all cases the two lower bars are straight and the two upper bars are bent up and carried over the main beam supports at each end to enable the effect of continuity to be taken into account in designing.

The main arched beams, which for the sake of appearance as well as lightness have open webs (see Fig. 3), vary in reinforcement according to the loads carried, the typical beam shown having nine main tension bars $d=1\frac{1}{2}$ in. at the centre of its span, as shown in section, the two outer bars marked A in the lower layer being continued right down into the supporting columns at either side, the centre bar B being bent up at an angle of 45° . Just before reaching the springing of the beam, the bars in the middle layer at the bottom (C and D) are treated in a similar manner, bar C not going quite so far into the columns as A, however, and bar D being bent up parallel to B; but at an earlier stage the top tension bars E and F are all bent up parallel to bars D and B, the two outer bars E being nearest to bars D, and bars F being still further from the springing of the beam.

The bars inserted near the top of the beam to assist the concrete flange to resist the compression stresses are $1\frac{1}{4}$ in. diameter, being nine in number in three layers, as at the bottom of the beam, the bars in the top layers being bent up into the columns at right angles a distance of 2 ft. 6 in. for fixing purposes, the three lower bars running straight into the column and getting a bearing only.

The spacing of the shear members of the beam is clearly shown in Fig. 3. In addition to the stirrups of $1\frac{1}{2}$ in. by $\frac{3}{8}$ in. hoop steel the bars marked L, J, G, H, $d=1\frac{1}{2}$ in., are provided to resist the shearing forces, whilst bars M, N, and O, $d=1\frac{1}{2}$ in., and P and R, $d=1\frac{1}{2}$ in., which frame the panels in the beam, also help to resist the shear stresses, and effectively bind the concrete together. Where the arched beams were supported by columns, extra bars were put in the columns (in this case 2 bars $d=1\frac{1}{2}$ in., $l=15$ ft. 6 in.) to resist the bending moment produced by the beams, and also to achieve fixation. The bars are marked S, and can be plainly seen in Section D.D., and also in the elevation of the column, being securely bound to the compression column bars, top and bottom, by 13 B.W.G. black wire.

The swimming bath, which is in reinforced concrete throughout, is adjacent to the gymnasium in the basement, and is also directly underneath the main hall. The bath proper is 66 ft. long by 21 ft. wide, with a varying depth from 4 ft. 6 in. to 7 ft. at the Caroline Street end. The bottom of the bath, which, of course, is on the slope, is 5 in. thick throughout, and is reinforced with $\frac{3}{8}$ in. diameter bars at 6 in. centres running both ways at top and bottom, the bars being carried up into the walls at the sides for a distance of 2 ft. 6 in. The walls of the bath are 5 in. thick at the bottom and 4 in. thick at the top, and in this particular instance they support one edge of the reinforced concrete platform, which runs round the bath at the top of the walls, and which is supported on the outer edge by brickwork. The reinforcement in the walls is so arranged that no outward

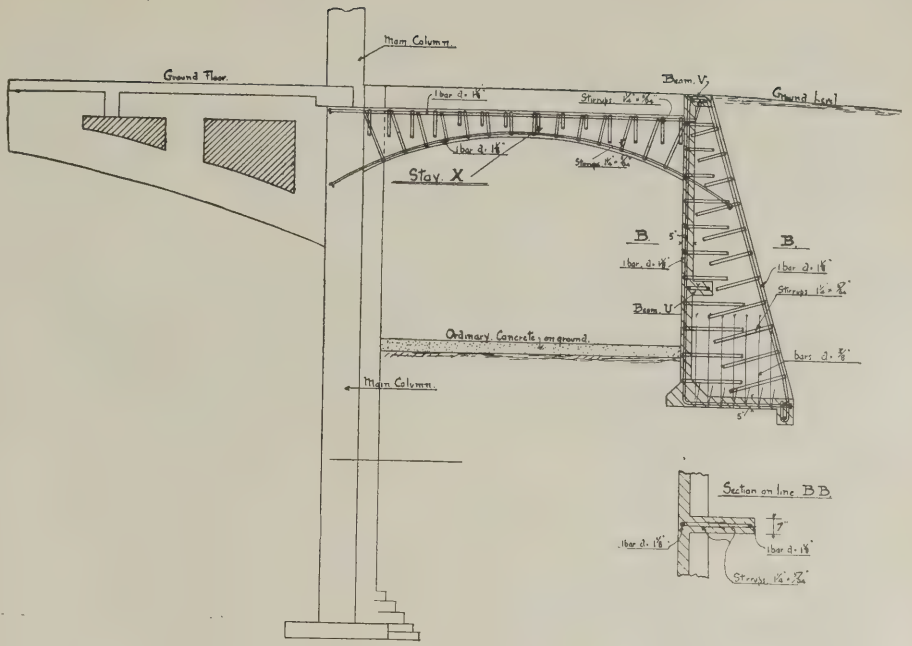

FIG. 1.—TYPICAL SECTION OF RETAINING WALL.

pressure is given to this platform, and therefore no lateral pressure reaches the brickwork. This is effected by treating the walls of the bath as acting in cantilever from the bottom, making the inner face of the concrete in tension, and therefore the reinforcement is placed nearest the inner face. The bars are $\frac{7}{16}$ in. diameter at 6 in. centres, placed vertically near the inner face, and $\frac{5}{16}$ in. diameter bars at 6 in. centres near the outer face, the bars being effectively anchored by being continued well into the bottom slab; $\frac{5}{16}$ in. diameter bars are placed horizontally at 6 in. centres for binding purposes, the shear members being made of $\frac{7}{8}$ in. by 19 B.W.G.. The counterforts, which are at about 6 ft. centres, are reinforced with two bars $d=\frac{5}{8}$ in., their chief duty, since the walls take practically all the pressure from the

water in the bath, being to form an ample bearing for the beams in the flooring round the tank. The bath has recently been tested with its full complement of water, and though the surface of the walls had nothing done to them, the result was remarkable, no actual leakage occurring at any spot. Apart from the slightly richer mixture for the concrete, the waterproofing medium used was good and the workmanship careful. The remainder of the basement does not call for special mention.

The main entrance hall at ground floor level in Great Russell Street, which is about 42 ft. in diameter, is an illustration of reinforced concrete as an architectural asset, shown by the winder staircase leading up to the lounge on the first floor and the circular columns, which are carried up past the first floor level to support the second floor over, their length

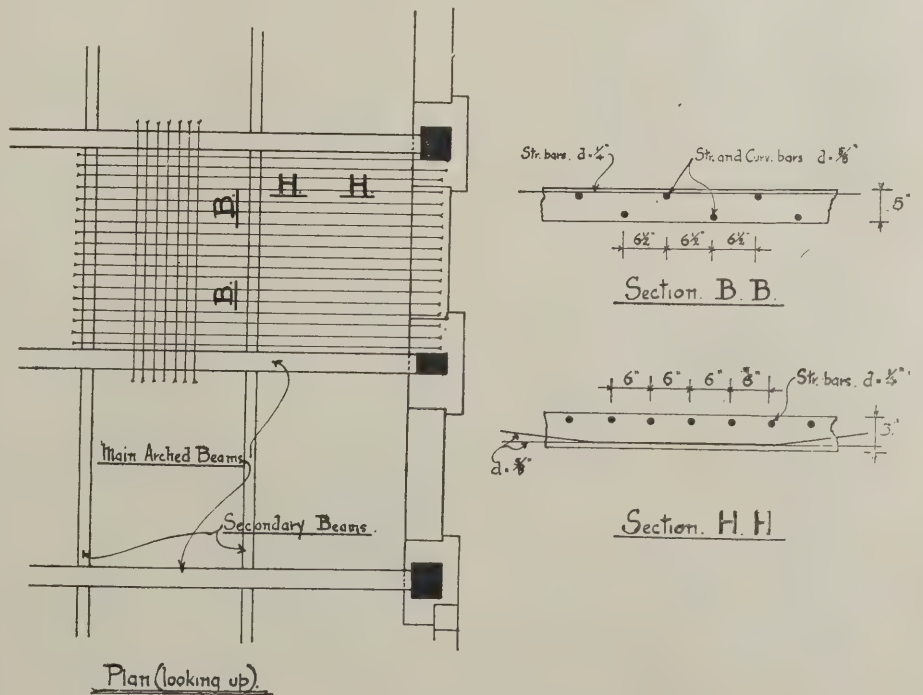

FIG. 2.—MAIN HALL FLOOR.

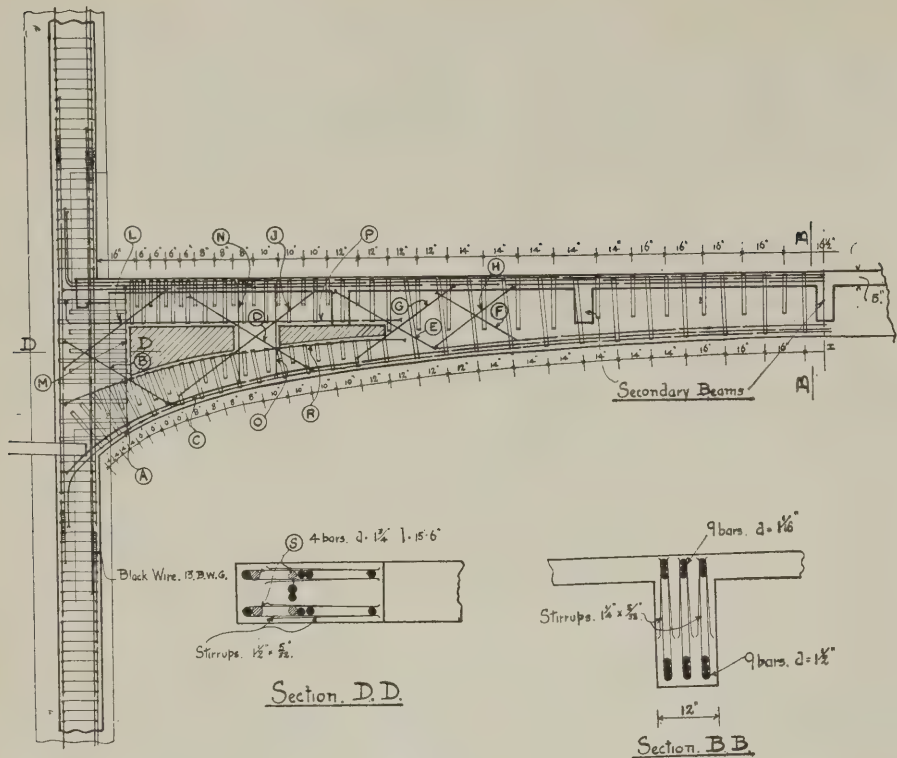

FIG. 3.—TYPICAL DETAIL OF ARCHED BEAMS, GROUND FLOOR.

being about 27 ft. The columns, which also support the staircase where necessary, are eight in number, being 21 in. square for a height of 7 ft. from the hall floor, the next 5 ft. 10 in. being 21 in. diameter, and the remaining length up to the second floor tapering up to 1 ft. 5 1/2 in. diameter at the top. The beams in the second floor over are arranged as cantilevers over these columns, to pick up a circular beam 7 ft. diameter, which, together with the radiating cantilever beams, form the foundation for the decorative plaster work which is now arranged in position. The special centering for the upper portion of these columns was made out of 2 in. by 1 1/2 in. battens, tapered as required and held together vertically at 2 ft. intervals by timber collars, which were calculated to the correct diameter. Although this arrangement necessitated the concrete being filled in from the top of the column, no difficulty was experienced on this account, the columns when struck presenting quite a finished appearance.

The gallery in the main hall is another example of the ease and economy with which reinforced concrete lends itself to cantilever construction. In the section shown (Fig. 4), the arrangement is particularly clear; the overhanging portion is about 6 ft. from the fulcrum beam, which is not excessively reinforced when one considers that it is only 3 ft. deep over all, and is on a clear span of 48 ft. The ends of the cantilever beam bars are securely embedded in a large ferro-concrete beam partition extending between the ground and first floors. The reinforcements generally of the cantilever beams are clearly shown in the section. The side galleries in the main hall overhang a distance of 10 ft. 4 in., the cantilever beams being 3 ft. deep, and the bars anchored back directly to the ferro-concrete columns supporting them. The test which was made on this portion of the gallery about eight weeks after it was concreted was extremely satisfactory, the maximum deflection being only 1/10 in., equivalent to 1/40 of the span, when the

FIG. 4.—SECTION THROUGH END GALLERY, MAIN HALL.

load was equal to 50 per cent. more than the load for which the gallery was designed.

The floor over the main hall is carried by arched beams very similar in construction to the arched beams at the floor level below over the gymnasium, while, in addition to these, in four cases there is a method of construction with regard to carrying the load encountered which is practically confined to ferro-concrete. It must be borne in mind that, having a span of 50 ft. to contend with, since the height from second to third floor levels is only 11 ft. 6 in., any beams in the third floor projecting 2 ft. or more below the ceiling would be most objectionable. The difficulty was got over by constructing beam partitions to carry the two floors, a part elevation being shown in Fig. 5. The beam illustrated, in addition to carrying a considerable portion of the second and third floors, also carries a part of the brick wall next the internal area, including the loads which come on to this wall from the third floor and the roof. The beam, which reminds one somewhat of a trussed steel girder in construction, has three door openings in it, 6 ft. by 7 ft. 3 in., 4 ft. 9 in. by 8 ft. 3 in., and 4 ft. by 8 ft. 9 in. respectively, as well as a window opening 3 ft. by 4 ft. 3 in.; and although the amount of concrete in the beam is only 507 cu. ft., from the mere fact that the weight of the reinforcing steel is nearly 7 tons, some idea of the enormous amount of work in dressing such a beam—that is, arranging all the steel in position—is quickly apparent. The beam at the top and bottom is 12 in. thick, whilst the panelling is only 6 in. thick, the main tension bars at the centre of the beam being eight in number, $d=1\frac{1}{4}$ in. The bars to take up the shear stresses and to rigidly connect the bars forming top and bottom booms of the beam are clearly shown. The bars in the compressive flange are $1\frac{1}{8}$ in. diameter, and at the centre are six in number, the bars in the 6 in. panels being $\frac{1}{2}$ in. diameter at 6 in. centres, both ways. The main connection of the bars in the top and bottom booms consists of four bars $d=1$ in. at intervals in the beam, which are hooked right round the respective bars, the concrete being increased to 12 in. thick for a distance of 9 in. These connecting bars are linked together by $\frac{1}{4}$ in. diameter links at 6 in. centres, and, as shown on plan, are practically 12 in. by 9 in. columns, acting as ties between the two booms of the main beam. These partition beams are unique, there being no other example in London of beams of this type and magnitude.

There are three other such beams between the second and third floors over the main hall, all being designed and constructed on similar principles, constituting an arrangement whereby the main hall floor, second and third floors are securely framed together, forming one huge monolith, somewhat similar to the cellular construction of the Britannia Bridge, which must necessarily tend to make the resisting powers of the various members when working together greater than when working individually, and also to add to the stability of the building generally.

At the third floor level, on the north-west side of the building, the internal area is increased in width; the main 14 in. area wall, in its new position, together with the loads coming on it from the fourth and fifth floors and mansard slopes, is carried by another partition beam,

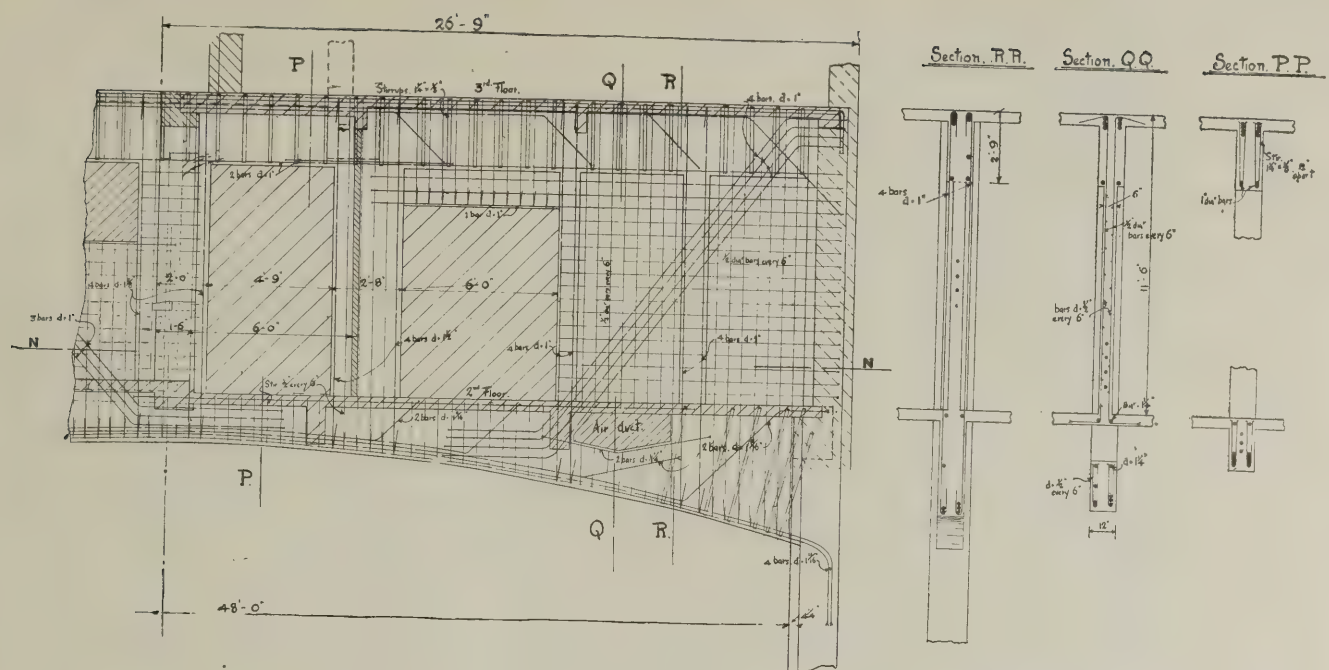

FIG. 5.—PART ELEVATION AND SECTIONS OF BEAM PARTITION.

THE NEW CENTRAL Y.M.C.A., BUILDING, TOTTENHAM COURT ROAD, LONDON.

which extends between the second and third floors, and forms the division wall between the photographic section and the corridor. This beam, which is 13 ft. 2 in. deep, is similar in construction to the other partition beams described, being somewhat lighter in reinforcement, since, although it is 67 ft. long over all, it is supported in two places by a ferro-concrete beam and brick wall respectively, running at right angles to it, thereby

reducing the effective span to about 29 ft. The beam is 6 in. thick between the floors, and where the bars occur for connecting the top and bottom booms of the beam, the concrete is increased to 12 in. thick for a length of 9 in., forming columns, as in the other partition beam described, at about 5 ft. 6 in. centres. Compared with the partition beam over the main hall, this beam only contains 487 cu. ft. of concrete and about two tons of reinforcing steel.

BEAM PARTITION IN COURSE OF CONSTRUCTION.

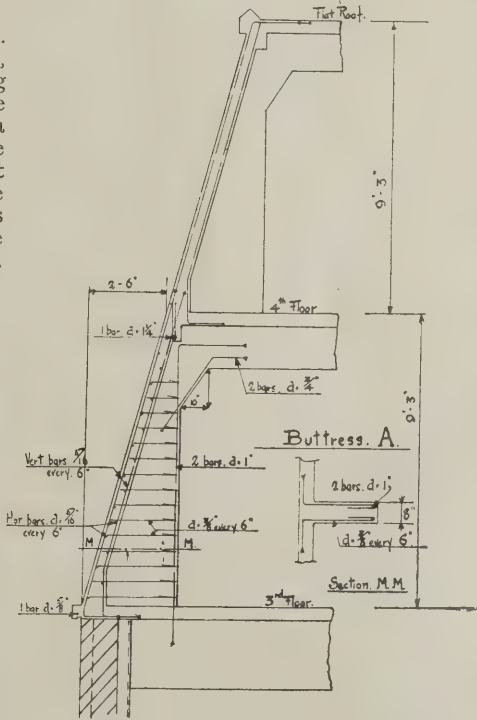

FIG. 6.—TYPICAL SECTION, MANSARD ROOF.

The mansard slopes, which commence on all sides of the building at the fourth floor level (those facing the area of the Great Russell Street continuing down to the third floor), as well as the dormer cheeks and heads, are all in ferro-concrete throughout. The slopes, a typical section of which is shown in Fig. 6, follow the usual practice, being arranged as flooring slabs 5 in. thick, sup-

GENERAL VIEW OF WORKS IN PROGRESS.

ported at the floor levels, buttresses being formed to stiffen the walls and pick up the beams of the floors, in sloping part of roof, where required. The reinforcement generally in the walls consists of $\frac{1}{4}$ in. diameter bars at 6 in. centres running both ways at each side of the wall, while in the section shown the buttresses have two bars $d=1$ in. on the tension side, the bars being continued well into the horizontal floor beams at top and bottom; the shear members consist of $\frac{3}{8}$ in. diameter bars at 6 in. centres hooked round the tension bars of the buttresses, bent at right angles and embedded into the slopes.

The dormer heads, which occur all round the building at roof level, some of which are circular and some square, were the subject of a special study, the concrete on being freed from the mould presenting a good finished surface, thus doing away with the cement rendering usually adopted in such cases. The timber moulds were made in the joiner's shop, the material being wrought, and photographs taken on the removal of the moulds by Mr. Lake, the clerk of works, plainly show the remarkable degree of finish obtained.

The main roof at fifth floor level is 5 in. thick generally, the beams and flooring slabs being arranged on the usual Hennebique principle; they call for no special comment, the carrying bars in the flooring slabs being $\frac{1}{4}$ in. or $\frac{3}{8}$ in. diameter, arranged at about 6 in. centres, alternately straight and curved, whilst the bars near the top of the slabs are $\frac{1}{4}$ in. diameter, running at right angles to the carrying bars every 6 in. These bars serve to lessen the effects of expansion and contraction on the concrete, due to the exposure to varying temperatures.

The falls necessary on the roof are made with a weak mixture of cement and coke breeze covered with a cement screed. This method of protecting ferro-concrete work exposed to the changes of weather has proved to be entirely satisfactory, especially where the spans of the beams have been large and the effect

of any expansion or contraction on the supporting brick walls or columns is a serious matter.

The water-supply tanks for the building are stored on the sixth floor, which is in the tower at the corner of Tottenham Court Road and Great Russell Street. This floor, which in addition carries the eighth floor and the dome, is carried at this level by two main beams 38 in. by 15 in. and 35 in. by 15 in. respectively, supported by ferro-concrete columns (two of which come from the basement and two of which are carried at the fifth floor level), the beams each having eight bars $1\frac{7}{8}$ in. diameter in tension and compression, and to resist the heavy shearing forces $1\frac{1}{4}$ in. by $\frac{5}{16}$ in. hoop steel stirrups. The flooring is 5 in. thick, being heavily rein-

forced with $\frac{1}{2}$ in. diameter bars at bottom both ways and $\frac{3}{8}$ in. diameter bars at top both ways, all bars at 6 in. centres. This floor, the area of which is about 77 sq. yds., is, owing to the heavy nature of the loads carried, easily the most heavily reinforced portion of the whole building, the total amount of steel used being about 9 tons, which works out at about 260 lb. of steel per yard super. of flooring.

The seventh floor, which is in the tower, assumes a circular shape, and is carried by four columns 9 in. by 9 in. and four columns 10 in. by 10 in., all of which start from the sixth floor below, the four larger columns continuing up to carry the eighth floor, which is also circular and which supports the ferro-concrete shell to the dome. A section through the

COLUMNS AND HALL STAIRCASE IN COURSE OF CONSTRUCTION.

shell of the dome in shown in Fig. 7; the covering stonework is supported by the eighth floor as shown, whilst the top stones are carried directly by the annular ferro-concrete ring 5 ft. 5 in. in diameter. The reinforcement of the ring consists of one bar $d=\frac{7}{8}$ in. at top and bottom, bent circular and lapped for a distance of 18 in., the bars in the slab being $\frac{3}{8}$ in. diameter every 6 in. both ways at top, and $\frac{1}{2}$ in. diameter every 6 in. apart, both ways, at the bottom. The bars in the shell are $\frac{1}{2}$ in. diameter 4 in. apart, the vertical and horizontal reinforcement being the same, all the horizontal bars being well lapped, while the vertical bars are continued down into the eighth floor slab at the bottom, and bent at right angles for a distance of 18 in. on each side for anchorage, the top ends being hooked round the $\frac{3}{8}$ in. bars in the annular ring at top, thus securely binding together the top slab and the walls. The walls are 5 in. thick, thickened out at base to 15 in. for a height of 2 ft. 6 in., the slab at the top being 10½ in. thick at the centre. There are eight open panels in the lower part of the wall, two bars $d=\frac{3}{4}$ in. being put in horizontally to take the ends of the vertical wall bars at the top of the opening, these bars also being well lapped.

Actual loading tests, in addition to the one on the gallery already mentioned, have been made on several selected portions of the building, and all with very satisfactory results; in no case was there any semblance of permanent set after the load was removed. A typical test might be mentioned on one of the second-floor beams over the library, the span being 28 ft., the beam being 12 in. below the 5 in. floor by 7 in. wide, reinforced with four bars $1\frac{1}{8}$ in. diameter, the shear members being stirrups made of $1\frac{1}{4}$ by $\frac{5}{16}$ in. hoop steel. A section was loaded to 50 per cent. above the normal working load as usual, deflectors being placed at points marked 1, 2, and 3, the calculated maximum deflection at the centre of the beam being 1.6 millimetres, or $1/5,330$ of the span, the figure embodied in the contract being $1/600$ of the span.

In conclusion, it is interesting to note that the total amount of concrete in the job used in connection with the reinforced concrete work is, roughly, 3,600 yds. cube, representing about 3,150 yds. cube of $\frac{3}{4}$ in. Thames ballast, 1,560 yds. cube of Thames sand, and 1,025 tons of Portland cement, while the amount of steel for reinforcing purposes is 510 tons.

The building, which is now completed, was designed by Mr. Rowland Plumbe, F.R.I.B.A., the ferro-concrete work being carried out by Messrs. Holloway Brothers (London), Ltd., Messrs. L. G. Mouchel and Partners acting as consulting engineers for the Hennebique ferro-concrete construction, and Mr. W. Lake as clerk of works.

THE PROPOSED CEMENT COMBINATION.

With reference to the particulars which were published in last week's issue regarding the formation of the British Portland Cement Manufacturers, Ltd., to take over and amalgamate a number of cement works outside the Associated Company, the Press Association states that the shareholders in the Saxon and Norman Portland Cement Companies, which have extensive works on the Newmarket side of Cambridge, received information on December 22nd that,

subject to ratification, arrangements have been made to sell the local factories to the new company.

It is stated that Lord St. Davids will be the chairman of the company, which will have an issued capital of £3,500,000, guaranteed by a number of leading London banking and financial houses. No public issue of stocks or shares or circulation of prospectuses will be made.

It is stated that the new concern will control an output of about 1,500,000 tons of cement annually. The price to be paid for the local companies, it is said, exceeds £185,000. The new company will have a working agreement with the Associated Cement Company, of which Lord St. Davids is also chairman, and the capital of both companies will amount to about £12,000,000. The two companies will control five-sixths of the cement production in the country. Mr. A. C. Davis, managing director of the Saxon and Norman Companies, will be managing director of the new company.

FIG. 7.—REINFORCED CONCRETE DOME. NEW CENTRAL Y.M.C.A. BUILDING, TOTTENHAM COURT ROAD, LONDON.

THE LIÉGE IRON AND STEEL INDUSTRY.

In reviewing the iron and steel industry for 1910 the American Consul for the Liège district of Belgium states that the output from 17 blast-furnaces, the number in operation during that year, was 784,890 tons of pig iron, valued at 50,320,000 francs, or 95,160 tons in excess of the figures for the previous year. The total consumption of ore was 2,009,250 tons. Of this amount 1,395,390 tons were imported from France, 369,590 tons from Luxembourg, 79,370 tons from Spain, 62,520 tons from Norway and Sweden, 49,010 tons from Germany, 25,620 tons from India, 7,400 tons from the United States of America, and 2,267 tons from other countries. The quantity obtained from domestic sources amounted to less than 1 per cent. There were six steel works in operation, with an increased output.

THE LOCK-WOVEN MESH SYSTEM OF REINFORCEMENT.

Fig. 1 of the accompanying diagrams shows a detail cross-section of the large Mansard roof that was erected to St. Anne's Vestry Hall, Soho. The "Lock-Woven Mesh System," which was employed here, as well as in the steel truss roof illustrated by Fig. 2, consists of a mesh formed of main or tension wires and secondary or transverse wires; the former being spaced from 3 in. to 6 in. apart, the latter about twice the distance apart of the tension wires. A lock or knot is mechanically placed over the tension and transverse wires at their intersection in the formation of the mesh, so that under ordinary conditions the wires cannot be displaced after fixing of the lock knot, which thus establishes a mechanical bond.

Lock-Woven Mesh, which is manufactured in an electrically driven loom of the most perfect type, is only limited in dimensions as to the width of the sheet or roll, the length being of any extent desired; although, as in practice it has been found that a single roll of mesh weighing more than 5 cwt. would be inconvenient to handle, the length may be said to be virtually governed by the weight. The average length of a 5 cwt. roll, however, being about 150 ft., and this being sufficient for the average building, no inconvenience arises.

The mechanical bond created by the knots forming the locks prevents the possibility of any slipping of the reinforcement within the concrete; and as, in the average building, a single continuous sheet of Lock-Woven Mesh reinforce-

FIG. 3.

FIG. 4.

or roof-panel, so that the system is particularly serviceable for foundations, floors, roofs, and walls of great length, especially for factory and warehouse floors where uneven loading may occur. Drawn steel wire, having an elastic limit of 64,000 lbs. per sq. in., with an ultimate strength of 89,000 lbs. per sq. in., is employed in the manufacture of Lock-Woven Mesh; the high elastic limit of the wire being very noticeable.

Lock-Woven Mesh is made with two styles of knots—namely, a lock knot (Fig. 3) and a spiral knot (Fig. 4). With the lock knot the tension wires are limited up to No. 7 s.w.g., but with the spiral knot, the tension wires may be of any size up to No. 3 s.w.g. The standard widths of fabric are 4 ft. and 5 ft., and the material is stocked in these widths in rolls of 200 ft. for the lighter weights, and 150 ft. for the heavier weights; but, as noticed above, there is no limit as to

length. A handbook illustrating and explaining the system in various applications—to floors, roofs, staircases, bridges, sewers, culverts, water-mains, reservoirs, swimming baths, shallow tanks, etc.—has been issued by Messrs. George F. West and Co., Caxton House, Westminster, who have taken over the Lock-Woven Mesh system from Messrs. J. H. Tozer and Son, Ltd., and this book is further valuable as containing useful diagrams, folding plates, and formulæ, as well as a unique history of reinforced concrete; and there are several views of important buildings in which the Lock-Woven Mesh system has been employed.

Reinforced Concrete in Yokohama.

A new building constructed of reinforced concrete, and provided with an automatic electric lift, has been completed in Yokohama for the Mitsui Bussan Kaisha. This instance of the utilisation of reinforced concrete is attracting much attention among builders and contractors there, and will probably lead to further developments.

Postponement of Meeting.

The presidential address on "Engineering Considerations in Wireless Telegraphy," which Commendatore Marconi was to deliver before the Junior Institution of Engineers on January 5th, has been postponed.

FIG. 1.—DETAIL OF MANSARD ROOF, ST. ANNE'S VESTRY HALL, SOHO, LONDON.

ment may be employed in the foundations, floors, and roof, it follows that a continuous bond is established in the concrete throughout; and if the mesh is anchored into the beams or walls at both ends, a considerable amount of rigidity is given to the structure. The continuity of the reinforcement also tends to economy in the amount of reinforcement to resist loading stresses, since slabs so reinforced may be considered as having fixed ends; while laps in the direction of the length of the sheets being seldom required, a less area of mesh will suffice than would be the case if the ends had to be lapped at comparatively short intervals; and the consequent economy in labour is obvious. What is even more important, the continuity of the reinforcement is a guarantee against the collapse of any floor, deck,

FIG. 2.—APPLICATION OF REINFORCED CONCRETE ROOF TO ORDINARY STEEL ROOF TRUSS.

SOME RECENT WORKS IN
REINFORCED CONCRETE.*

BY 'G. C. WORKMAN, M.S.E., M.C.I.

The object of this paper is to describe a few of the numerous works recently executed in reinforced concrete, and to bring out some of the more interesting features of each particular case and to show how various difficulties have been overcome.

One of the first large buildings with which I had to deal was the second tobacco warehouse, for the Bristol Docks. This work was carried out under the Docks engineer, and the contractors were Messrs. W. Cowlin and Son, of Bristol.

The general dimensions of the structure are: 200 ft. in length by 102 ft. in width and about 96 ft. in height, and there are altogether nine floors calculated for a superload of $1\frac{1}{2}$ cwt. per square foot.

This building is identical in appearance to the first tobacco warehouse, but the inside is in reinforced concrete instead of being in steelwork with concrete floors.

Besides the advantages of fire resistance and economy which this building offers over the first one, the internal accommodation is larger on account of the walls being only about 14 in. in thickness throughout the height of the building, instead of the considerable thickness of brick walls required in the first building. These thin brick walls or panels were supported at each floor by lintels, and the building has been divided in two by a partition in reinforced concrete 6 in. thick.

The various floors were arranged in such a manner as to minimise the risk of fire by cutting off any particular floor from the others. The level of the floors is slightly raised at all lift openings and doors, so that it would be possible to flood any particular floor with a couple of inches of water if required.

This warehouse has been erected on reinforced concrete piles varying in length between 40 and 50 ft. 650 piles were required for the foundations.

The load coming on each of the internal pillars amounted to 300 tons, and it was necessary, in order to transmit this load on to the ground, to group six piles together, uniting the heads by means of a cap.

Each pile was calculated to stand a safe load of 56 tons, and the diameters of the piles varied between 14 in. and 15 in.

The piles were driven into the ground by means of a steam monkey weighing two tons. The particular pile shown on the screen took about three-quarters of an hour to drive to its final set at a depth of about 45 ft.

In showing a photograph of one of several buildings erected at Rainham, Essex, for Messrs. J. C. and J. Field, Ltd., the architects being Messrs. Scott and Fraser, and the contractors, Messrs. William King and Son, of London, the author explained that the site is situated on the riverside and is extremely marshy, so that the buildings had to be constructed on spread foundations or rafts in reinforced concrete.

It is noticeable that although this building contains very heavy machinery and tanks for the manufacture of soap, it has been possible to spread these loads on to the ground evenly at a rate of only about a quarter of a ton to half a ton per square foot.

Reinforced concrete buildings, being monolithic and lighter than brick or masonry work, are very well adapted to cases where unequal settlement is likely to occur, especially when such buildings are erected upon a reinforced concrete raft.

Of extensive premises erected in the city for Messrs. J. Grossmith, Son and Co., perfumers, the architect was Mr. H. A. Saul, and the contractors were Messrs. Peacock Bros., of Brixton, for the first portion of the building, and Messrs. Stuart's Granolithic Co., Ltd., of London, for the second portion. The building has altogether eight floors, the interior and roof being entirely in reinforced concrete. An interesting feature of the building is that the heavy front and side lintels are supporting the whole of the brickwork above. A considerable amount of difficulty was experienced in the design of the roof, owing to the fact that one of the slopes is much longer than the others, producing unequal thrusts. All the steel units for the various beams and pillars were prepared at Brixton in the contractors' workshops, and carted on to the site ready to be placed in position. It was necessary to proceed in this manner owing to the lack of room on the actual site of the building. Of the hostel for women students at the Birmingham University, the architects were Messrs. Buckland and Farmer, of Birmingham, and the entire building was carried out by Messrs. Richard Fenwick, Ltd., contractors, also of Birmingham. The total area of flooring was approximately 13,000 square feet. The floors were tested with a load 50 per cent. in excess of the specified superload, and the deflection did not exceed a thousandth part of the span.

There seems to be a considerable difference of opinion between the various methods of stopping the concreting in floor slabs, in beams, and in pillars. Personally, I am of opinion that the best method of stopping the concrete of the floor slabs is to stop the work over the beams, also that the concreting of beams should be stopped over the points of support. Concerning the pillars, the footings should be made first and the body of the pillar carried up to the level of the soffit of the beams, the remaining portion being concreted at the same time as the beams.

One of the most interesting buildings with which I have been associated is the new Western District Post Office, which was erected about two years ago under the supervision of the Office of Works, the contractors being Messrs. William King and Son, of London. This building, which is situated between Cavendish Square and Wimpole Street, comprises a block of 200 ft. frontage and 160 ft. in depth, with basement, ground floor, first and second floors, and flat roof. Owing to the fact that only four large pillars were allowed in the centre of this floor space, the spans between these pillars and the outer walls varied between 45 ft. and 39 ft., so that the four pillars in question support loads of over 200 tons each. One of the chief features of the building is that the ends of the principal beams carrying respectively the first floor, second floor, and roof are suspended bodily by means of strong steel stirrups to upper beams 6 ft. high, forming the internal walls surrounding the inner court above the various floor levels. By this means it was possible to obtain a maximum height for the windows, which was a condition stipulated by the Office of Works. This condition, however, brought about a question as to whether

this method of suspension could be used without danger, the two beams having a span of 39 ft., and supporting the first floor with a superload of 1 cwt. per square foot, the upper supporting beam having a span of 45 ft. There was no evidence that this particular arrangement had ever been adopted before, at least for spans of such large dimensions. The problem was solved in a satisfactory manner, with the result that the two suspended beams 39 ft. long each, and the beams across the inner court supporting the skylight, appear to have been made in one single span of about 118 ft.

Another noticeable feature is found in the extensive beams over 12 ft. in height, which carry the other end of the suspended beams. These 12-ft. beams have a span of 45 ft., and it was necessary to provide in the portion of these beams underneath the first floor a series of large windows situated below the neutral axis of the beam, which occurs approximately at the level of the first floor. Large areas of flooring were tested, the specification being one and a half times the superload, and the deflection not to be greater than 1-600th of the span. The deflection recorded in the beams did not, however, exceed 1-1500th to 1-5000th of the span, and no permanent deflection was noticed.

I would take this opportunity to state that in my opinion it is essential to place underneath the beams which are to be tested a few strong emergency props not touching the soffit of the beam by about $\frac{1}{2}$ in. This has the effect of reassuring the men who are carrying on the loading operation, and it also has the effect of preventing any sudden collapse which might be due to unforeseen circumstances. In showing a view of the front elevation of the Western District Post Office in Portland stone, executed by Messrs. Galbraith and Son, the author remarked that all the other walls were made in reinforced concrete 5 in. thick. The London County Council By-laws which were shortly to be revised would, he hoped, encourage architects to study the question of reinforced concrete applied to the front elevation of buildings.

Among the views shown was one of a large factory erected about eighteen months ago at Bailiffe Bridge, near Leeds, for Messrs. T. F. Firth and Sons, Ltd., carpet manufacturers. The architects were Messrs. Walsh and Nicholas, of Halifax, and the contractors Messrs. Henry Atkinson and Sons, Ltd., of Leeds. The main building is four storeys high and 176 ft. long, with a width at one end of 70 ft. and at the other end of 111 ft., the building being in the shape of an L. The total floor area is approximately 52,000 square feet. The factory is built on a very steep incline, and to overcome difficulties of levels on the site from the ground to first floor a retaining wall 16 ft. high was constructed in reinforced concrete. The staircases throughout the building are also in this material. The work being situated in the very midst of the York stone district, local prejudice prevented treating the external walls as a distinctly concrete building. A compromise was effected by facing the main reinforced concrete pillars and the lintels of the various floors with local self-dressed wall stones 5 in. on bed. The recessed wall spaces under the salt-glazed brick arches are finished with rough-cast. The author was informed that this large factory does not exceed in price per super-yard of floor area a similar factory which was built twelve years ago in the same neighbourhood with steel girders and stanchions, wooden floors

*Extracts from a paper read at the twenty-first ordinary general meeting of the Concrete Institute on December 14th, 1911, at Denison House, 1296, Vauxhall Bridge Road, Westminster, S.W.

and stone walls. Fires are very frequent in this district, causing tremendous loss and inconvenience. The value of the carpets stored in this warehouse being very considerable, it was decided to adopt reinforced concrete for this building. In this particular instance a very large saving was effected in the yearly premiums owing to the low rate which the insurance companies are prepared to grant to buildings in reinforced concrete.

Other works described were the new Government buildings erected at Kingston, Jamaica, for the Government (architects, Messrs. Nicholson and Corlette, of London; the contractors, Messrs. William Cowlin and Son, of Bristol); the new King's House at Kingston, Jamaica, which contract was carried out simultaneously with the one previously described, under the same architects and by the same contractors; the new Holloway Money Order Department, which is the latest of a series of large buildings for the extension of post-office facilities in London, under the instructions of H.M. Office of Works (the work was executed by Messrs. William King and Son, of London; the completed elevation in brickwork and masonry having been carried out on a separate contract by Messrs. Leslie and Co., Ltd.); and several other works.

Dealing with the question of superloads, the author said he would like to mention that it had been his experience that architects and engineers are inclined to specify superloads which are obviously far more considerable than what is really necessary. This is probably due to the fact that in many cases reinforced concrete is a novelty to them, and by specifying a comparatively high superload they hope to guard themselves against failure of the work. It is well established, however, that any failures which have occurred have been due either to the premature removal of props and centering, or, in a few isolated cases, to faulty design, so that in reality nothing is gained in security by specifying a higher superload than is required. In the case of the Holloway building, the Office of Works, who are thoroughly acquainted with the use of reinforced concrete, have not hesitated to specify a superload of $\frac{3}{4}$ cwt. per square foot, which is quite ample for their requirements, and which has the advantage, of course, of being economical.

THE CONCRETE INSTITUTE TRANSACTIONS AND NOTES, VOL. III.

This volume, to which reference is made in another part of the present issue, contains, besides the matters there mentioned, a very useful collection of material. Numerous accessions to the library are recorded, and the notes include a series of abstracts of publications on concrete—an important feature which will no doubt be continued, and might be with advantage further developed. The lectures and discussions, visits, and other functions that occurred during the period covered are reported and illustrated; and the interim report of the Tests Standing Committee on "The Testing of Concrete, Reinforced Concrete, and Materials Employed Therein," is included, as well as the report of the Science Standing Committee on "The Rusting of Steel Inside a Concrete Covering," and that of the Reinforced Concrete Practice Standing Committee embodying suggestions on "The Standardisation of Drawings on Reinforced Concrete Work." The paper read in June by Mr. Alfred E. Corbett,

F.R.I.B.A. (of Woodhouse, Corbett and Dean), on the Y.M.C.A. Building, Manchester, is accompanied by a dozen folding plates, as well as smaller illustrations.

TRADE AND CRAFT.

Callender's Dampcourse Specialities.

We have received for examination and notice a sample of Callender's "Ledkore" Dampcourse, which, as its name indicates, consists of a core of sheet lead with a special bitumen covering on both sides. It is an ideal combination, because it admits of the lead being used in economically thin sheets, and also serves to protect it. Moreover, the bitumen, when, as in the present instance, it is of the right quality, is pliant without being squeezable, and thus can accommodate itself to the possible settlement of the building in which it is used.

In a pamphlet "Concerning Dampcourses," issued by Messrs. George M. Callender and Co., Ltd., contractors to the Admiralty, War Office, Office of Works, etc., 25, Victoria Street, Westminster, the various materials in general use as dampcoursing are passed in review. It is mentioned that a double layer of good sound slates, set in cement, so as to break joint, will fulfil the first two of the following three essentials of an effective dampcourse: (1) Absolute impermeability to moisture; (2) a "life" equal to that of the building itself; and (3) pliability. Slate, however, is too rigid to resist successfully the effects of settlement; and although it is still used by builders of the old school, it can only be regarded as a makeshift. Of course, sheet lead would be far preferable to slates, but then the necessary thickness of the lead would render its use prohibitive. Moreover, it seems to be obvious that the unprotected lead would be much more liable to the corrosion from which lead is not entirely immune. A dampcourse properly made from pure refined natural bitumen, without admixture, is no doubt always effective; but occasionally an excess of the material may, in certain circumstances, exude beyond the face of the wall, and this, besides causing unsightliness, may give rise to misgivings that, while really groundless, are sometimes best avoided; though in circumstances in which exudation does not occur, or does not meet with objection. Callendrite dampcourse is of proved efficacy. The lead and the bitumen in combination, however, are mutually helpful towards the desired object of producing a really perfect dampcourse, at once impervious and permanent, and unaffected by climatic changes.

Messrs. Callender's "Ledkore" dampcourse is made in three grades—A, B, and C—differing in the thickness of the lead core used, and is put up in standard rolls 24 ft. long, cut to the usual wall widths. As the inventors, well-nigh forty years ago, of the original pure bitumen damp-proof sheeting, which is known to architects and builders all over the world, Messrs. Callender hold a unique position in the waterproofing trade, and their extensive experience has enabled them to evolve a special bitumen material which is dense and tough, yet perfectly pliable. The firm publish a list of places in which their materials have been used. These include cathedrals, churches, and chapels; public buildings, banks, and institutes; factories, business premises, offices; schools and colleges;

barracks, workhouses, police and fire stations; hospitals, infirmaries, and asylums; hotels, inns, and theatres; estates, residences, shops, etc. The mere classification is of formidable extent; and the details occupy several pages of the firm's catalogue, in which there are also many pages of views of important buildings in which the firm's dampcourses have been adopted. There are given, besides, the results of several tests of the firm's dampcourses; the purity and quality of the materials, and their efficiency in use, being fully attested by such well-known authorities as Messrs. David Kirkaldy and Son, Mr. W. H. Stanger, Mr. H. Wilson Hake, Mr. A. Dupré, and Mr. H. Graham Harris.

John Tann's Safes and Doors.

The King and Queen, in travelling on board the "Medina" to India, necessarily took with them the costly Crown Jewels, for display at the Durbar, and these were kept secure in a safe supplied by John Tann, of 117, Newgate Street, E.C., who is able to state, in the catalogue now before us, that "No John Tann's fire-resisting safe has ever had its contents destroyed by fire," and that "No John Tann's thief-resisting safe has ever been opened by burglars."

The firm (originally named E. Tann and Sons) invented and patented in 1843 the system of rendering safes fireproof which is now generally in use. The fire-resisting composition employed by John Tann consists of "a light non-conducting mineral substance intimately mixed with a crystalline material; the former preventing the great heat reaching the contents of the safe in the event of a fire, and the latter, by giving off some of its water of crystallisation, moistening the contents and rendering it absolutely impossible for them to get burnt." John Tann, it is mentioned, was also the originator of the compound drill-proof unbreakable steel plate which was patented in 1865, and consists of alternate layers of hard high carbon steel and tough mild steel rolled and welded together into one solid plate; the combination of tough mild steel and the high carbon steel producing a plate which is unbreakable as well as drill proof. An up-to-date innovation is a device for protection against the oxy-acetylene blowpipe.

Besides a large array of safes of various sizes and patterns, adapted to a great variety of purposes (including special designs for use in ecclesiastical buildings), the catalogue contains a special section showing the "Anchor Reliance" and other fire and thief-resisting doors and frames for a comprehensive variety of purposes and situations, and of many different patterns. Full particulars of these are given in the catalogue, in which also are listed many special locks, steel boxes, shelves, and office fittings generally. No architect specifying fittings for banking and commercial premises, etc., should fail to consult this catalogue.

Some New Tiles and Bricks.

Messrs. James Brown (London), Ltd., of Essex Wharf, Durward Street, Whitechapel, are now supplying a hand-made sand-faced roofing tile (holed and nibbed), 11 in. by 7 in. by $\frac{5}{8}$ in., made at their Brentwood brickfields and, in addition to the red moulded bricks which they have manufactured for the past thirty years, they now supply 2 in. mouldings and window architraves of antique designs; a special catalogue relating to the latter has been issued recently, a copy of which can be obtained upon application.

MEMORIAL BRONZE IN EALING HOSPITAL.

This memorial was designed by Messrs. Hall-Jones and Cummings, architects, of Westminster. It was modelled by Mr. Frank Bowcher, the enamels in the corners being by Mr. Nelson Dawson.

DETAIL OF GARDEN ENTRANCE, "THE HOO," WILLINGDON, NEAR EASTBOURNE.
EDWIN L. LUTYENS, F.R.I.B.A., ARCHITECT.

Extensive alterations and additions have been carried out at "The Hoo," Willingdon, under the direction of Mr. Lutyens, the original building having largely disappeared in the process. The new work displays many features which have become characteristic of the architect, the rubbed-brick niches over the doors to the dining-room and the drawing-room being particular instances. Thin old hand-made local bricks and Portland stone have been used for the exterior, the roofs being tiled.

THE ARCHITECTS' & BUILDERS' JOURNAL.

VOLUME 35. No. 186.

NOTE : The List of Contents will be found on page IV. of the front advertisements.

The meaning of "Baroque" and "Rococo."

THE tendency of modern writers on architecture to divide everything up, as it were, into chapters seems to have led to the use of the words "baroque" and "rococo," as if they characterised some particular period or style in architecture. In the late Russell Sturgis's Dictionary of Architecture we find "Rococo" defined as "the architecture of the century beginning about 1660 A.D.," a period which includes St. Paul's and the Invalides—"are they 'rococo'?" We saw recently a new German publication entitled "Rococo Architecture," comprising a series of plates illustrative of Renaissance architecture generally, a great deal of which is in a refined, pure, and severe style, and certainly merits no such classification as would be implied by the cant term "rococo." But the worshippers of classification go further than that, for they appear to distinguish another style of Renaissance architecture as "Baroque," and to separate this from "Rococo." A fine volume of photographs of late Italian Renaissance architecture, just published by Mr. Heinemann, is entitled by its editor, Signor Ricci, "Baroque Architecture and Sculpture in Italy"*; and apparently in his view Baroque is a style that precedes Rococo, as, in speaking of France, he observes that "In France Baroque art coincided with Louis XIV., while the Rococo style flourished under Louis XV." According to that showing, then the quadrangle of the Louvre is Baroque, and the Panthéon is Rococo. It is surely only necessary to state it in that way to show the absurdity of such a classification of architecture under such terms.

Some writers on architecture seem to have applied the term "Rococo" to Renaissance architecture generally, much in the same way that, in the eighteenth century, the word "Gothic" was applied to mediæval architecture, rather as a half-contemptuous summary of a style of architecture which they thought uncultured. The word "Gothic," however, has survived to take on a different and more serious meaning; the word "rococo" has not, and ought not to be applied to a great style which includes many works of the highest and most serious type of architecture. "Rococo," if it has any definable meaning, means a style of decoration which is "rocky," i.e., exuberant in style and protuberant in surface (the latter seems to be the original meaning of the word), and rococo architecture means, or ought to mean, merely a vulgar and tawdry style of Renaissance architecture or ornament. There is a great deal of rococo ornament at Versailles, for instance, but the architecture of the palace, considered broadly, though rather commonplace, is not rococo in the proper sense of the word. And as to the supposed difference between "baroque" and "rococo," we defy any one to draw any definite line of demarcation between them, founded on distinctions of style. A writer may choose, arbitrarily, to group buildings of one date under the term "baroque" and those of another date under the term "rococo," but there is no kind of

architectural sense in the definition; both words really mean, not a style, but a florid and tawdry manner of design; and the only difference between them is that the one word is French and the other Italian.

We may therefore take Signor Ricci's volume of illustrations of "Baroque Architecture in Italy" as simply meaning late Renaissance architecture in Italy. How far this is from showing any distinct type which can be classed as baroque we see in plates 10 and 11 of the illustrations, in which the cupola of San Carlo al Corso at Rome faces an illustration of the Salute church at Venice. The two designs have nothing in common at all in point of taste and style; they are within twenty years of each other in date, but they might have belonged to different centuries. The Salute church is within every one's recollection; it is an example of exceedingly exuberant treatment of Renaissance materials; the Roman cupola, by Pietro da Cortona, which we reproduce, is a piece of sober refined work on severely Classic lines. The architectural atmosphere of Rome may have

CUPOLA OF S. CARLO AL CORSO, ROME,
BY PIETRO BERRETTINI DA CORTONA (1612).

*Baroque Architecture and Sculpture in Italy: By Corrado Ricci, Director General of Fine Arts and Antiquities in Italy. London: W. Heinemann, 1912. Price 25s.

THE MADONNA DI S. LUCA, BOLOGNA, BY CARLO FRANCESCO DOTTI (1723).

From "Baroque Architecture and Sculpture in Italy."

been more favourable to restraint of style than that of Venice; apart from that, the difference probably lay in the individual taste of the architects.

Signor Ricci, however, in his introduction to the collection, is manifestly the apologist of the more exuberant productions of late Renaissance architecture and sculpture. In England we do not regard these as the finest emanations of the genius of the Italian Renaissance; and it is rather significant of the state of feeling about art in modern Italy that Signor Ricci, who holds the responsible post of Director General of Fine Arts, should stand forth as sponsor, not for the real glories of the greatest period of Italian art, but for the architecture and sculpture which represents for the most part a period of decadence. What modern Italian sculpture has come to those who have seen its occasional examples sent to the Salon; fortunately very little of it gets as far as London. But one ceases to be surprised at this when we find the author of this short treatise lavishing admiration upon such specimens of rampant bad taste as the Piazza Navona and the Trevi fountains at Rome. It is strange to think of such work being admired in the country which gave birth to Donatello. That the late Renaissance Italians did exhibit a remarkable talent and originality in the treatment of fountains is quite true; but it is not in these scrambling heaps of contorted figures and artificial rockwork (in this case truly called "rococo") that their best efforts are to be found. The really good Italian fountains are those which are framed in a formal architectural setting. Of these there are many fine examples, in some cases with a good and refined architectural treatment, and they thoroughly understood the use of steps in connection with fountain architecture; we see this in the case of the fountain architecture at the Villa Mondragone at Frascati, and that (better known) at the Villa d'Este at Tivoli, both of which are illustrated in the book

under notice, and both show architectural framework of a fairly severe and refined standard, such as we are accustomed to associate with the idea of Italian architecture. We will select for illustration, however, one which shows what could be done in this way with the more corrupt and abnormal forms of late Italian Renaissance, that by Claudio Venardi in the garden of the Villa d'Este. Some of the architectural details of this are really horrible—the terminal figures, for instance, with their legs twisted into spirals; but it cannot be denied that there is an astonishing largeness and vigour about the whole thing, with its bold interrupted scroll pediment at the top. As a new work it would have repelled one; as an old and weatherworn erection it is rather striking. It is worth note that this does not belong, as one might have supposed, to one of the latest periods illustrated, and that its date (1573) is exactly the same as that of the soberly designed fountain with the staircase round it, in the grounds of the same villa. Here again, as in the case of the Roman and Venetian cupolas before referred to, the style of the two things might be a century apart; another proof that essentially "rococo" character lay as much in the personal taste (or want of it) of the designer as in any general tendency of the time.

This fountain, however, supplies an example of what Signor Ricci seems to think is the great claim to our admiration of the late Italian Renaissance both in architecture and sculpture—that it has more in it to astonish us than the art of any other period; and he quotes a saying of an Italian poet, Marino, whom he calls "the Baroque poet par excellence," to the effect that "the aim of the poet" is to *surprise* us, and that he who cannot astonish us is a failure. There could not be a worse dictum as a philosophy of art, if one wants the highest art; but it explains and to some extent excuses the aberrations of decadent Renaissance art. The time was one of bombast

and magnificence in the general order of life, and the architecture and sculpture expressed this. The author says, with some truth, that we can hardly judge of such art fairly in comparing it with our modern dress, life, and manners :—

"Let us take the magnificent theatre interiors built by the Bibiena. Many critics consider them overloaded with consoles and balustrades, and tormented with curves. But if for the audiences of to-day (the men with bald or closely cropped hair, in their tightly fitting grey or black coats, the women with their prim coiffures and discreetly rouged complexions), it were possible to substitute the resplendent public of the day when the Bibiena designed these theatres—the damasks, jabots, laces, embroideries, ribbons, feathers, and flowing wigs—and if we could illuminate these with thousands of canals inside and outside the boxes, would the architecture seem as heavy as it now does?"

There is some truth in that; and would not the saloons of these Baroque palaces, he says, the heavily decorated stucco ceilings of which seem about to crush us, have quite a different effect if filled with the old imposing furniture with its painting and gilding, candelabra, pictures with frames in high relief, etc.? He certainly makes a point there, and suggests a consideration that is sometimes overlooked in judging of old interiors without their original accompaniments.

It is true, too, that the period of the seventeenth and eighteenth century Italian Renaissance was one of a remarkable energy and vigour in architectural production; disapprove as one may of their taste, one cannot pass them over; they are too insistent for that. But to admit that is not to admit that they represent the best art; that is, however, what Signor Ricci's essay seems to imply; and, so far, it is a protest in a wrong direction. He seems to be obsessed with the greatness of Bernini; a fact which in

itself seems to show how completely modern Italy is separated from the artistic thought of other nations. No-where else in Europe would a critic think of regarding Bernini as one of the world's great artists. He was a most wonderful man, it is true, in his energy and versatility, and his power of swiftly modelling sculpture; but the sculpture most easily modelled does not always last the longest; and in architecture his one great idea is his colonnades before St. Peter's, for which we may well be grateful to him. His colossal baldachino inside the cathedral is a huge piece of pretentiousness; and he very nearly did St. Peter's a worse service by adding to the façade two of the most villainous-looking angle cupolas ever designed, drawings of which are extant. Mr. Tavernor-Perry, who went into the evidence on this subject some little time back, believed that one of these cupolas was actually erected; it so, apparently some Pope who realised what an ugly thing it was had the good sense to have it pulled down again. Bernini was a power in his day, no doubt; but to find him spoken of in Signor Ricci's essay as if he were a kind of heaven-sent genius and a regenerator of architecture and Italy is, in the present day, really astounding. Equally so is it to find the author selecting Sta. Maria della Salute as the finest church of the period in Italy; a building generally regarded merely with indulgence by architects, as one that is picturesque in spite of the crudeness of its detail.

The collection of nearly three hundred plates, however, to which Signor Ricci's essay is an introduction, is a fine possession in itself. It contains, it is true, a good deal of bad art, but it is a stimulating collection to the imagination in the wealth of architectural and sculptural detail shown in it, some of which contains suggestions which might be worked out to better account in a different manner of treatment. Among the architectural illustrations we reproduce the charming group of the church of Madonna di S.

STUCCO DECORATIVE WORK IN THE PALERMO MUSEUM, BY GIACOMO SERPOTTA (1704).

From "*Baroque Architecture and Sculpture in Italy*."

FOUNTAIN IN THE GARDEN OF THE VILLA D'ESTE, TIVOLI,
NEAR ROME, BY CLAUDIO VENARDI.

From "*Baroque Architecture and Sculpture in Italy.*"

Luca at Bologna, a work of the early eighteenth century, by Francesco Dotti; in spite of its late date, it is in a quiet and restrained architectural style which could not possibly be characterised as "baroque." The sculpture decoration by Serpotta from the Palermo Museum, dated 1704, is a good example of the sculpture style of the period, spirited in design, though deficient in the repose and severity of line which characterised the earlier and great school of Italian sculpture. We may add that in spite of the title of the book, the illustrations include a sufficient proportion of really fine examples of Renaissance architecture to give it a value for the architect. It is certainly a most attractive volume, excellently produced, and as such we have pleasure in bringing it to the notice of our readers.

London and Suburban Roads.

IN reference to the suggestions of the London Traffic Report that an understanding should be come to with local authorities around London as to providing for main routes through their districts, as part of a comprehensive plan, a correspondent of the "Daily News" argues that all such understandings would have to be made compulsory on the local authorities, or they would have small chance of being carried out to any practical accomplishment. Here he is very likely right. Local authorities, as a rule, consider nothing but the interests of their own borough, and one can imagine a local council resisting obstinately the proposal to create a wide road through their domain in view of its forming part of a main route out of London. They will argue—We do not require a road of any such width in our district; why should we go to the expense of making it because London wants it? The Traffic Report, it is true, suggested the expenditure of public money, where necessary, in compensating a local authority for the loss of land in setting back their building lines for a main road; but it may be doubted whether compulsion will not be necessary. The only way to ensure the carrying out of a general scheme of adequate main roads is to have the roads

set out and planned by a central authority in London, and the local authority then to receive a mandate to lay out such part of each road as comes through their district, of the prescribed width, as a duty compulsory by law. The question of compensation for the compulsory taking of land could, of course, be settled by the usual methods of procedure. The object would be, not to victimise a local authority, but to compel them to fall into line in the carrying out of a central scheme.

Opening Out Southwark Cathedral.

THE idea which has been started, and to which we have already referred, of opening a cleared space between Southwark Cathedral and the river, seems to have excited great interest and to find wide approval, especially among those who are acquainted with the adjoining neighbourhood, and who wish to see an open space provided for its crowded population. That is a very important point, no doubt; but the one which we naturally think of more is to see a fine prospect added to the river bank, as a break in the rather sordid line of old warehouses, and to see a remarkable building brought more into prominence. The nave of the cathedral, of course, is modern work, by the late Sir A. Blomfield; a good example of modern Gothic, and that is about all that can be said of it. But the choir contains the finest Early English work to be seen in London, and is little known. Americans, we are told, visit it a good deal, because they find it duly described in their guide books; but Londoners, who do not use a Baedeker to their own city (some of them might learn a great deal if they did), know very little of it, and few of them ever see it. If the discussion of the subject draws more attention the choir of Southwark, it will have done something.

The Late Professor Legros.

IT is announced that an exhibition of the works left by Professor Legros is to be held shortly at the Fine Art Society's rooms in Bond Street. The works to be exhibited include, apparently, not only painting and drawings, but gold-points, crayons, and medallions and sculpture. Legros was a very versatile artist, but we were not aware before that he had included sculpture among his productions. Whatever he has left, however, will be the work of an artist of original genius, and who was always serious in his aims, and the exhibition is likely to be of considerable interest.

A New Building Estate.

IT is announced that the Wembley Hill Estate, which is the property of the Wembley Park Estate Co., has been sold to a Bedfordshire syndicate to be laid out in plots for building small houses on, to cost, with the land, £350 to £400 each. The houses are to be "ideal homes," a phrase which we suppose has become classical since the "Ideal House" Exhibition, two or three years ago. Here is an opportunity for making a new departure in building estates of this kind. At Letchworth, Hampstead, and Gidea Park, the ideal home has taken far too much the form of what we may call the artificial picturesque; the provision of houses with small windows, high roofs, and in general rather thin walls. This last named quality originated in the endeavour at Letchworth to show how large a cottage could be provided for a very limited sum of money, and cost had to be saved in the walling, so that a 14 in. outside wall became quite a phenomenon. That is not the way to build ideal homes; pretty cottages of this kind may be very charming in summer, but they will be very cold in winter. Nor is it "ideal" to build with low walls and high-pitched roofs so that nearly all the upper storey is in the roof, and the sides or angles of the rooms are too low to stand up in, by reason of the slope of the rafters. High roofs are not necessarily picturesque, except by association; old cottages had high-pitched roofs because village carpentry was not very practical; there is no common sense in repeating this method of building now, and it merely makes cold and inconvenient upper storeys. Nor is there

anything beautiful in having very small windows, which again are only picturesque by association; practically, and for modern dwellings, small windows mean deficiency of light, and are not conducive either to health or convenience. If the projectors of the new building estate will make a fresh start, and show that small houses may be made pleasing to look at, and much more comfortable to live in, without imitating ancient cottages, they will be doing a good work and setting an example which may be followed elsewhere. We have seen quite enough of the "ideal home" in its pseudo-picturesque form; we should like to see it take a more practical and reasonable aspect.

Backward By-Laws.

COMPLAINT is made that the Manchester Corporation by-laws for new buildings and improvements are, particularly as regards steel construction, a very serious handicap on development. For steel construction no detailed by-laws are laid down such as those which apply in the case of much of the brickwork and woodwork which has been steadily replaced by steel construction for many years. Architects can at once discover if their brickwork designs meet with the approval of the authorities, but neither architects nor engineers can ask for the passing of steelwork designs until after the actual material has been prepared and fixed. It would surely be fairer, a correspondent very justly remarks, to judge the suitability of a structure as it is shown on the original plans rather than later, when alterations may involve heavy expense. There is no part of a building that costs so much to modify, after once being put together, in its final intended position, as the steel-work. "Of course, there are qualified engineers at Manchester whose work the Corporation would never question, and the present practice is to their advantage and interest. But," he adds, "with the greatly increased growth of industrial Manchester it is impossible that the design of the steelwork of all structures should be in the hands of a few men. It is time that we had a department like that of the London County Council, which thoroughly investigates proposed steelwork constructions, together with the other work which comes under the by-laws to be passed with the plans. No data that can be obtained is neglected by the L.C.C. department, and there is no difficulty in getting within the scope of its clear requirements and then satisfying the engineers and so far guaranteeing the final acceptance of the work proposed, which is of the utmost importance to the architect and to the contractor." It is very refreshing to find the London County Council regarded as a model for imitation. Undoubtedly they owe this proud position to the very useful guidance they have accepted at the hands of architects and builders, and it is to be hoped that the Manchester Corporation is equally accessible to similar influence for its own good.

The Invention of Portland Cement.

IT is seldom possible to determine quite definitely who was the absolute originator of any given invention, even when the invention is comparatively modern, like that of Portland cement. Usually there are many successive steps towards perfection, and progress is assisted by a plurality of persons; and Portland cement, as we now know it, owes its perfection to the contributory suggestions of scores or hundreds of fertile brains. Recognition of this fact, however, does not greatly, if at all, discount the interest that most people take in the search for origins; the excitement being usually in the chase rather than in the capture. Apparently it is of no great practical importance to ascertain who originated Portland cement; and nevertheless it is clear that there are many who, having long supposed that Joseph Aspdin was the inventor, have had this notion disturbed by the reiterated claim that the honour belongs to Isaac Johnson (who died a few weeks ago at the age of 101), and are desirous of escaping incertitude. In another part of the present issue we print an article that may serve either to remove or only to deepen the perplexity to which

several of our correspondents have confessed; the effect depending upon individual temperament. It will be seen that Dr. Wilhelm Michaelis, the eminent chemist, having gone into the subject pretty thoroughly, does not hesitate to award the palm to Isaac Johnson. He of course admits the priority of Aspdin, whose patent was taken out in 1824, whereas Johnson seems not to have taken up the subject until the early 'forties. Johnson advances the claim, however, and Dr. Michaelis supports him in it, that although Aspdin got on to the track of a discovery, he, being no chemist, never evolved a satisfactory commercial product; and that Johnson, having an adequate knowledge of chemistry, was "the first manufacturer of a cement that would pass the test of the exacting engineers of British and foreign Governments." It is, apparently, a case of "honours divided"; and probably most people will be quite content to leave it at that, even though the evidence adduced may not be such as to satisfy the most rigorous and exacting demands for irrefragable proof.

The Temple of Apollo Palatinus.

MR. OLIFFE LEGH RICHMOND writes to correct a misapprehension which seems to have arisen with regard to his theory concerning the Palatine Hill and the group of Augustan buildings which once adorned it. He complains that his theory seems to have been confused with that of Professor Pinza; whereas in Mr. Richmond's view the Temple of Apollo and the Palatium of Augustus (a building distinct from the *domus Caesaris* or "house of Livia") faced across the Circus to "Diana of the Aventine," as Romus faced towards Remus at the taking of the first auguries. The front of these buildings, with nine arches of the Danaid portico to the east, formed the northern side of the "area" of Apollo; on the east this area was bounded by the Latin and Greek libraries, with more of the portico in front of them; on the south ran the rest of the portico as far as the Stair of Cacus, upon foundations destroyed in the great landslide. The writer says that the contention of a critic that "the main argument against the new theory is supplied by the statement of Festus that the symbolic *Roma quadrata* was situated in front of the Temple of Apollo, whereas it must certainly have lain behind the temple," entirely misrepresents the idea. The square Rome of Augustus was a plot of ground of a certain measure upon which the Temple of Apollo and the Palatium stood. Festus (and Solinus) refers to that side of the square which was marked out by *termini*, and extended from the south-eastern corner of the temple steps to the brow of the Stair of Cacus on the west of the area. This measured side of the square was thus both "in area Apollinis" and "ante templum," and Mr. Richmond claims that his theory is the first to reconcile the two authorities.

The Future of Whitehall.

THE scheme of lining Whitehall with Government buildings is likely to be advanced one step further for it is stated that in the next Session the First Commissioner of Works will ask Parliament to sanction the acquisition of land on the eastern side of Whitehall for an extension of official premises. This will involve the absorption of practically the whole of Whitehall Gardens and the buildings now occupied by the Board of Trade, the Crown Agents for the Colonies, and the Committee of Imperial Defence. Nothing has transpired as to the intentions of the Government regarding the Departments which would be transferred to the new buildings, but there is a general recognition of the advantage accruing to the public service by the concentration of the important administrative offices. There are extensions proceeding at the present time which will cost over half a million. The offices of the Local Government Board and the Board of Education are being enlarged at the bottom of Parliament Street, already a considerable part of Great George Street has been built upon, and it will not be long before the remainder of the site will be occupied by the Government offices.

WHAT IS WANTED IN THE BUILDING TRADES.—I.

"IN THE DAWN OF A PERIOD OF 'PROSPERITY.'"

THE demand for new buildings has been slack for a longer period than usual. Various causes for this are suggested, such as the unprecedented calls for capital by other industries and by foreign and Colonial peoples, and the disturbing effect of legislation affecting real estate—for example, the Small Holdings Act, the Town Planning Act, the Increment Value Duties and the valuation incidental thereto, and the National Insurance Act.

Whatever the cause, however, the worst seems past, and a better demand may soon be expected, because the large questions about to engage the attention of Parliament will relieve the building trade from further interference for a time, while the probability that plenty of capital will soon be set free for investment in real estate, the changes already in progress in ownership of land, and the activities arising out of the working of the above-named measures, are likely to stimulate building work.

In the dawn of a period of prosperity it is well to "look back at a period of adversity" and to endeavour to draw from it such lessons as may enable good use to be made of the former and wise provision prepared against the return of the latter. Let us see how the building trade has come through its period of adversity as shown by the records of bankruptcy. For the five years ending 1910 the total number of failures were as follows:—

Builders ..	2,305	with liabilities totalling	£3,048,016
Bricklayers and Plasterers, etc.	156	"	46,815
Carpenters and Joiners ..	285	"	122,418
Decorators, Painters, Plumbers, and Glaziers ..	943	"	352,518
	3,689	"	£3,569,767

When examined year by year the numbers of failures of builders were as follows:—

1906	508
1907	531
1908	505
1909	367
1910	394
	2,305

Business failures are usually the result of causes operating over a series of years, so that it is a fair inference that the whole of those 2,305 firms who failed during the five years ending 1910 were really already in financial straits in 1906, although only 508 out of 2,305 did actually fail in that year.

But the point to bear in mind is, that *actual failures only represent a part of the total suffering of and injury to the traders*, because firms in financial straits can only keep themselves afloat by turnover of business, and hence are compelled to take even unprofitable prices rather than diminish this turnover. On a falling market, therefore, the policy such firms are compelled to pursue depresses selling prices abnormally, to the great detriment of their fellow competitors.

Comparing the number of failures in the various trades, a descending scale would be headed by grocers (with about 766 failures a year) followed by builders, publicans, farmers, drapers and haberdashers, bakers, boot and shoe makers and dealers, tailors, butchers, and decorators, painters, plumbers, etc. (with about 188 failures a year). It may be noted that in all these trades the professional side of the industry is but little developed; but when we compare them with the professional workers—such as accountants, architects and surveyors, chemists and druggists, clerks

in Holy Orders, doctors and surgeons, solicitors, and engineers—and note that the highest number of cases in any of these professions did not exceed 73 during the period in question, while with two exceptions (engineers and chemists) they were well below 50, the difference seems to require explanation. Of course, something must be allowed for the smaller number of men in some of the professions, but not very much, because, although the building trade employs a large number of men, the actual firms engaged are relatively small in number. When, therefore, every allowance has been made, one cannot fail to be impressed by the fact that in a period of five years of depressed trade, which must have affected alike architects and surveyors and builders, the total number of failures among the former was 110, as against the 2,305 builders (or, if the sub-trades are included, 3,689). What can be the underlying cause? The obvious answer is difference in the relative risks. It is true the risks differ in kind, but do they differ much in effect? Architects have to obtain commissions and are unable to advertise their own merits: they have to depend upon friends or upon the public's appreciation, which is as variable as the wind. The risk of getting a footing, let alone rising, in the architectural profession is probably as great as any risk in any trade or profession. The builder's risk is of a different kind, and lies rather in the variations of demand, variations of weather, uncertainty of ground, risks arising out of labour troubles, and the like. To those accustomed to face and deal with them they are not all so formidable as they look, and the most important of them—namely, variations of demand—affects architects and builders alike. On the whole, difference of risk does not seem to account adequately for the difference in the number of failures.

A less obvious answer is want of knowledge; not so much want of ordinary education, or commercial and financial knowledge; not so much the want of it in individual cases either, for there are plenty of individual cases where such knowledge is present; but the want of a widespread prevalence of what in short may be called "professional qualifications."

The building trade is a very complex trade, involving the organising, directing, at one time or another, of 40 to 50 sub-trades, and the proper carrying out of it—at all events where large works are concerned—demands faculties of a high order and of diverse kind by the heads of firms, and in lesser degree by the staff and workmen.

Certain complaints are not uncommon in the building trade which seem to show that want of knowledge is largely responsible for its unenviable notoriety as a risky business.

The most significant of these complaints is the one, heard at every builders' gathering, of the abuse of the system of inserting in quantities provisional sums for work to be done by specialists. Complaints of disloyal and cut-throat competition are also common, and these point to want of knowledge as their real cause. Complaints by architects of insufficient technical skill on the part of workmen obviously have a similar basis. The decay of apprenticeship also may be due to a want of appreciation of the value of training, which amounts to the same thing.

When one remembers, further, the way the building trade is recruited, the slender educational and technical qualifications possessed by apprentices and journeymen, the way the ambitious journeyman blossoms into the small builder; and when we further reflect upon the *laissez-faire* way in which all this takes place, and the entire absence of any control or test of qualification at any stage of the evolution; we can hardly fail to conclude that it is highly probable that want of knowledge is at the bottom of most of the disagreements and disasters that occur in the building trades.

[A further article on this subject, containing suggestions well worthy of the serious consideration of both architects and builders, will appear next week.]

MR. CASS GILBERT AND THE WOOLWORTH BUILDING.

A BUILDING has just been commenced in New York which is of unique interest. This is the Woolworth Building, designed by Mr. Cass Gilbert.

The problems involved in the design of a "skyscraper" are obviously of very complex character from the engineering standpoint, and the architect finds a task no less easy of solution, for the simple reason that the scale on which these buildings are conceived is colossal, and one which, before the present era, found no expression in architecture. Consequently, rules and orders which proved to be satis-

expression of the conditions, on which basis has been founded the estimate of engineering structures designed with no other idea than the fulfilment of a definite practical purpose, as, for example, the design of a locomotive. But against this idea may very well be set the question as to whether every condition imposed is a legitimate or proper one, so that, however much a building might be expressive of the conditions it was intended to fulfil, the conditions themselves might be fundamentally wrong, and the solution of them correspondingly deficient. This has a very direct

MR. CASS GILBERT.

Drawn from life for "The Architects' and Builders' Journal" by H. Farini.

factory in the buildings of antiquity are wholly inapplicable to buildings of this new class. The structures to which the skyscraper is most nearly allied are the towers of the Gothic builders and the campanili of the Renaissance churches in Italy, but all these, in comparison, are such small affairs that the conditions of design become wholly different; more especially as a giant shaft of offices requires, as a first condition, abundance of windows uniform in size, which, in itself, creates a problem of fenestration that would seem to be almost impossible of satisfactory solution. It has been argued that the real test of an architectural design to be sought in the fact as to whether or not it is the true

application to the case of the "skyscraper." These huge buildings have been the outcome of two chief factors—namely, the excessive cost of building land in the centre of American cities, and the desire for advertisement on the part of the promoters of the schemes.

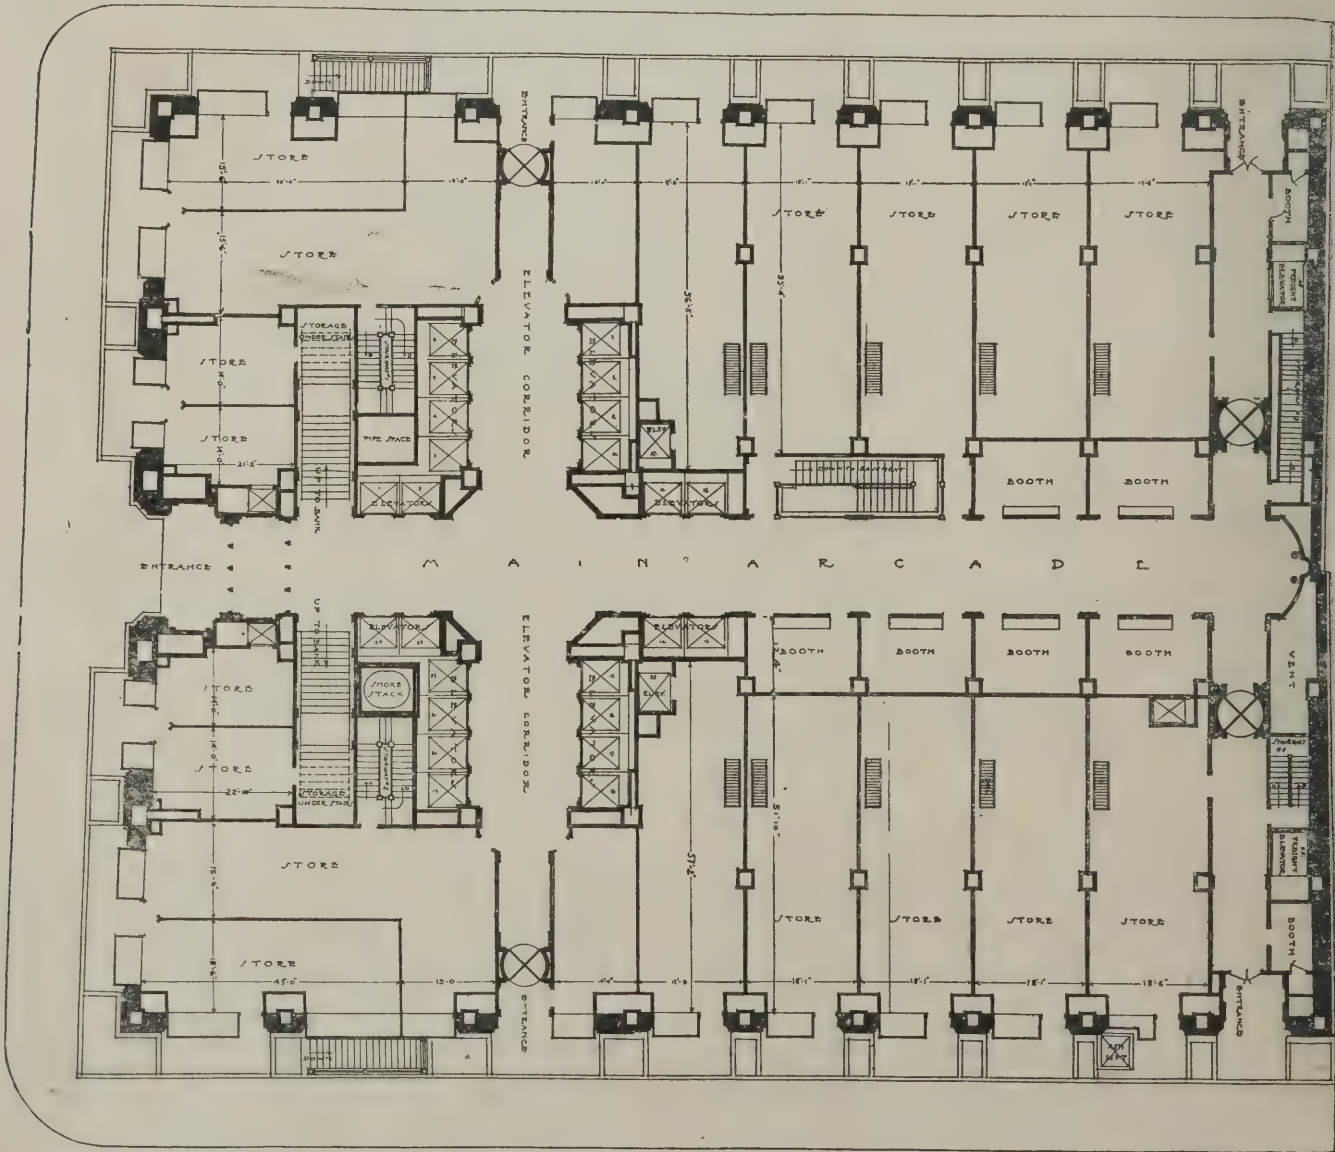

As to when the craze for height may end, it is at present impossible to say. Not so long ago a building of 20 or 30 storeys was regarded as phenomenal, but structures of such height are far exceeded by several of the new buildings in America, and in particular the advance will be marked by this amazing new Woolworth Building. Some striking figures in regard to the latter are given below, but before

proceeding to them it may be well to quote the following from an American contemporary as indicating that even in the home of the "skyscraper" there is already a protest being made against it; and if this protest were to receive the support which it undoubtedly deserves, the time might soon come when the erection of immense towers of offices such as the Woolworth Building would cease, and the buildings would be conceived on a scale more within the limits of reasonableness. Our contemporary, referring to the Woolworth Building, says: "Just why such a tall structure is considered desirable is something of a mystery, and it has manifest disadvantages to the city. The Singer and Metropolitan towers are advertisements of two of the leading advertisers of the country. There is no such excuse, however, for the rearing of this great pile, shutting off the light of its neighbours (there is no law as to ancient lights in America!), darkening the streets, and containing a population of several thousand people whose concentration on a little piece of ground will add another heavy burden to the transportation facilities in the vicinity. The construction of a lofty structure like the new municipal building to accommodate most of the city departments is a manifestly wise undertaking, for the advantages of concentrating most branches of a business under one roof are thoroughly well proved. But it is difficult to see any utility for general office purposes in such a towering structure as the new skyscraper. In these days of almost perfect telephone service, it is no longer necessary for men engaged in the same or allied pursuits to huddle together in a few congested blocks and to overcrowd the street cars and subways

serving small areas." Many of those possessing the strongest individuality are leaving the crowded down-town sections of the city for the more convenient and less congested regions about the great railroad terminals, where, even if the rush of business is just as great, there is more elbow room."

The Woolworth Building, it appears, was conceived some years ago, but the problems involved in its design were so considerable that it was only after a great amount of study that the scheme was successfully drawn out. Mr. Gilbert, the architect of the building, is one of the leading American architects of to-day, and has carried out a number of buildings possessing great architectural quality. His later work is in the same American Beaux-Arts manner that has given to the cities of the United States so many notable buildings. In the present instance, however, Mr. Gilbert has reverted to his first manner, and has designed the Woolworth Building on Gothic lines. The scheme has grown with the conception, as may be judged from the three sketches here reproduced, the final design showing a building which will be the highest in the world, the only other structure exceeding it being the Eiffel Tower.

It occupies a corner plot on Broadway, measuring 155 ft. by 200 ft. Work on the sub-structure is now in progress, the foundations having been commenced at the beginning of November last. It need hardly be said that the foundations for such a structure need to be of the greatest stability; in the present case they are carried down to solid rock, 110 ft. below the street level.

THE WOOLWORTH BUILDING, NEW YORK CITY: GROUND-FLOOR PLAN. CASS GILBERT ARCHITECT.

Sixty-nine concrete piers are being constructed by means of pneumatic caissons, these piers being loaded to a maximum of 18 tons per sq. ft. and resting on grillages which comprise principal foundation girders 8 ft. deep, 32 ft. long, and weighing 60 tons.

From the accompanying illustrations it will be seen that the building comprises a main rectangular block, from which rises a high tower crowded by a pyramidal roof, but it is only when the exact heights are set down that one gains an adequate idea of the colossal scale on which the structure is designed. Let it be stated, then, that the height from the pavement level to the top of the main roof, at 31st floor level, will be 400 ft., the tower (86 ft. by 84 ft. at its base) being an additional 270 ft. in height from the 31st floor to the 50th, from which level rises a pyramid 105 ft. high and 54 ft. square at the base, containing the five highest floors, and an observation gallery at a height of 730 ft. Thus, the building in all comprises 55 stories, of an average height of 12 ft. 6 in., the total height being 775 ft. from pavement level and 870 ft. from the foundation grillages to the top of the tower. There are only two storeys below ground, the cellar floor being 37 ft. 6 in. below street level.

As stated, the Woolworth Building will exceed in height any other structure. The nearest to it in height are the Singer Building, New York, in which the highest office floor, in the tower, is the 40th, 524 ft. above pavement level, above which is a dome rising to 668 ft.; and the Metropolitan Life Insurance Building, New York, which comprises a main block of eleven stories extending to 160 ft., with a tower of thirty-seven storeys rising another 500 ft., the total height being 683 ft.: while, as another structure of a similar character, there is now being erected, from designs

by Messrs. McKim, Mead and White, a municipal building of twenty-five storeys for the City of New York, which will be 560 ft. in height. In comparison with the foregoing, the heights of some London buildings may be given thus:—

Westminster Abbey towers	225 ft.
Imperial Institute tower	270 ft.
Westminster Cathedral tower	284 ft.
Houses of Parliament (Victoria Tower) ..	340 ft.
St. Paul's Cathedral (from pavement to top of cross)	365 ft.
the heights of the New York buildings being:—	
Municipal Building	560 ft.
Singer Building	668 ft.
Metropolitan Life Building	683 ft.
Woolworth Building	775 ft.

So that the Woolworth Building will be far and away the highest building yet undertaken. (NOTE.—The Eiffel Tower cannot fairly be taken into comparison, being an engineering *tour de force* with no interior.)

One of the most difficult considerations in connection with the Woolworth Building has been that of wind-pressure, for it need hardly be pointed out how great and how complex are the stresses set up in such a structure. A uniform wind-pressure of 30 lb. per sq. ft. over the entire building has been provided for, the stresses being met by special bracing systems. The floor loads are taken at 150 lb. per ft. super. on the ground and basement floors, and 75 lb. on each of the others.

The building will be of steel-frame construction, the outer walls being of granite up to the fifth floor and of terra-

THE WOOLWORTH BUILDING, NEW YORK: TYPICAL OFFICE FLOOR PLAN.

cotta above. No less than 20,000 tons of steel will be used. Partition walls will be 8 in. thick, built of hollow bricks, and floors will be of hollow terra-cotta arches, with the exception of the basement and ground floors, which will be of reinforced concrete 5 in. thick, serving as diaphragms to distribute and resist the balanced exterior horizontal pressures. The structural steel will be protected by 1 in. of cement mortar, and by having all interior spaces filled solid with concrete or mortar, and enclosed within an outer shell of terra-cotta at least 3 in. thick. Everything possible, in fact, will be done to render the building fire-resisting. No wood will be used anywhere. The window-frames and the doors will be of pressed steel, the floor surfaces of mosaic, and all exposed exterior windows glazed with wire-glass; while the pyramidal portion of the tower

will be sheathed with tiles and covered with copper. Two floor plans are here reproduced, from which the interior arrangement is best studied. It may be mentioned, however, that there will be twenty-six lifts, the shafts of which will be fireproofed, and in addition there are provided four fire-escape stairways, widely separated from one another, and each enclosed in a fire-resisting shaft.

Altogether the building is one of exceptional interest, both from the point of view of the architect and of the engineer. It is being erected for Mr. F. W. Woolworth, from designs by Mr. Cass Gilbert, the engineer responsible for the steelwork being Mr. Gunvald Aus. The general contractors are the Thomson-Starrett Company, the American Bridge Company being the contractors for the steelwork. The total cost is put at £2,000,000.

BUILDERS' HOURS IN THE
MIDDLE AGES.

BY HENRY LITTLEHALES.

There is reason to suppose that builders' workmen in the Middle Ages toiled for ten hours a day, the Saturday being reckoned as a whole, not a half-day, as we may gather from the fact that an equal payment was made for each of the six working days which a workman put in when engaged at so much per day.

Our knowledge respecting builders' hours in the Middle Ages is, it must be admitted, somewhat scanty. We have very many mediæval builders' bills with the description of the work done and the amount paid in wages to each separate workman engaged, but these accounts generally give little more than these bare facts.

Two mediæval documents, however, remain to-day which refer specifically to the number of hours worked, and from these two documents we may obtain a very fair idea of the hours of the builder's working day in the Middle Ages.

Our first document is now in the Public Record Office, labelled Exch. Acc. 477-12. This valuable manuscript is the ledger of a mediæval builder, and the items set down in the book are those connected with the erection of a substantial portion of a great house at Cuddington, not far from Epsom, in Surrey, in the year 1538.

Many details of the wages paid to the workmen will be found set down in this ledger and entered with an unusual fullness. Let us turn to the work done by the carpenters. Here we find that a large number of carpenters were engaged at wages varying in amount. Some were engaged at 8d. a day, some at 7d., 6d., and even 5d. a day. Let us take the case of John Simons, whose name is first on the list, and who is described as being engaged "at viiid. the daye." Now if we turn to an entry in another part of the book, giving the payment of his wages, we shall see that he is paid "for every x. howers viiid." Such, too, we shall find to be the case with Edmund Bedell, the first on what we may call the sevenpenny list; and so, too, is the case with William Young, engaged at 6d. a day. All these three men, with many others, were, we find, engaged at a fixed sum by "the daye" in one part of the book, and are entered in another part as being paid the same amounts respectively "for every x. howers."

The same facts also occur in the accounts of wages paid to the labourers. We find here the entry: "Labourers serving the masons, rated for every x. howers iiiiid." Of these labourers we may give the specific instance of John Wright, who was engaged by "the daye" at 4d., and whose name appears also in the list of those serving for the ten hours for 4d.

We may now turn to our second document, which is to be found amongst a series of ordinances drawn up for the town of Beverley, in Yorkshire, and which have been carefully edited by Mr. Leach under the title of "Beverley Town Documents."

On page 56 of Mr. Leach's book we find the following order fixing the working hours for builders' men in the town of Beverley in 1467: "From Easter to 15th August they shall begin work at 4 a.m. of every working day, and leave off at 7 in the evening, and during the whole season shall have at 6 a.m. an interval of a quarter of an hour for drinking, and at 8 half an hour for breakfast, at 11 an hour and a half to dine and sleep if they like, and at 3 p.m. half an hour for drinking."

Final Study.

THE WOOLWORTH BUILDING, NEW YORK.

After 15th August to Easter then next, they shall begin at the beginning of the day, and leave off when the light of the same day fails, and in this season they shall have half an hour for drinking or breakfast if they like at 9 a.m., and a whole hour at 12 to eat, and at 3 a quarter of an hour for drinking."

It will be seen by the above that the builder's day in 1467 contained 12½ working hours in the summer, and about 7 hours in the winter, an arrangement which gives an average working day through the year of about 10 hours.

From these various details we may perhaps not unfairly conclude that we have in some degree established the fact that the builder's workman in mediæval England worked a ten-hours day.

Overtime in the Middle Ages.

The references to overtime in mediæval accounts, though neither abundant nor particularly explicit, may perhaps be regarded as sufficiently numerous, and clearly enough expressed, to furnish us with a very fair idea of the system commonly in use.

A large volume of building accounts of the time of Henry VIII. in the Record Office (Exch. Acc. 477-12) refers to a number of masons: "Workyng their hower tymis and drynkyng tymis at 1d. the hower." In other words, these masons were paid at the rate of 1d. an hour to work during their hours of rest, food, and drinking.

As the mason worked generally at the rate of about 8d. a day for ten hours, it will be seen that the rate of payment for overtime was very much the same in proportion to the wage paid for ordinary work as one would expect; that is, overtime was paid for at the rate of about time and a quarter.

The "drynkyng tyme" was a recognised interval in the builder's days occupying as distinct a place as the "howers" set apart for rest and food.

In MS. 479-9 we read: "Paid the sondery masons carpynters and laborers ffor theire rewardes workinge in their howre tymes and drynkyng tymes for the expedicion of the work." This, it will be observed, states the reason for the working of overtime.

In the MS. 459-22 we read: "Laborers workyng theyr howers and drynkyng tymys at ob (that is ½d.) the howre." And in MS. 477-12 we read:—"Laborers servyng fremasons, workyng their hore tymis and drynkyng tymis, ratid for euery x howers vd." That is to say, the labourers attending the masons worked overtime for a payment of a halfpenny an hour, a very similar increase above the ordinary wage to that paid to the masons for their overtime. In MS. 459-22 we have the entry:—"Massons workyng howre tymys and dryn (kyng tymys) for the hasty expedyscyyn of certen wy(n)dows and do(ores)." This entry tells us both the reason for the overtime and also the nature of the particular work done in it.

At times the remuneration for overtime took the form of ale in place of money, but such a form of recompense was probably only given when the time worked was of little more than nominal duration. An instance of such a recompense occurs in MS. 474-7;—"Item, for Ale gyven to the plombers and others whan they wrought after there houres to helpe vp with led." Evidently the plumbers and others merely shifted some lead.

The working of overtime by plasterers is mentioned in MS. 479-11.

POCKET BOOKS AND DIARIES FOR 1912.

We have received various calendars and diaries from firms associated with the building trade.

Mr. J. Percy Day, of 3, Victoria Street, Westminster, sends us a combined blotter, calendar, and diary for 1912, attractively bound in violet cloth. Mr. Day is the London Representative of the "Austral" Window Balance Co., Ltd., of Manchester, and is also proprietor of the Euboeolith Patent Flooring.

The Saxon Portland Cement Co., Ltd., Cambridge, send a very neat little leather-covered, rounded-edged, back-looped, waistcoat-pocket diary, with insurance coupon included.—A handsome red-leather-covered, self-opening pocket diary, with rounded corners and back loop for pencil, comes from Messrs. Siemens Bros. and Co., Ltd., and Siemens Brothers Dynamo Works, Ltd., who have usefully included in it a few illustrations of some of their specialities, and of works in which they have provided installations.—The "Mechanical World" Pocket Diary and Year Book, and the Electrical Pocket Book from the same firm (Emmott and Co., Ltd., 20, Bedford Street, W.C.), are each published at sixpence net, and each is a marvel of cheapness.

From Messrs. Robt. Ingham Clark and Co., Ltd., varnish manufacturers, London (with branch factories at Paris, Hamburg, New York, Buffalo, Chicago, Sydney, and Bridgeburg), we have received a most tasteful calendar in Adam style; also a copy, specially bound in red leather, of the "British Almanac and Companion for 1912," including an insurance coupon. The latter is a volume of 446 pages, containing a well-digested mass of useful information. Seating plans of the principal London theatres, concert-halls, and music-halls are a notable feature.—"The Master Builders' Handbook and Diary for 1912," the official Year Book of the London Master Builders' Association, is now still further improved by the addition of such new features as a very useful digest of the more important law-cases, of interest to architects and builders, which have been decided during the past twelve-month. The history of the Association, the proceedings of the Conciliation Board, the lists of members of the Association, of district surveyors, of London Labour Exchanges, etc., as well as the many other items of practical information, have been revised up to date. Leading legal cases, in which important principles of the law with regard to building have been established, are included, as well as the text of the London Building Acts Amendment Acts, the R.I.B.A. Form of Contract, the agreements drawn up in connection with the various sections of operatives, and a mass of useful data with regard to the various trades. Portraits are given of Mr. G. Bird Godson, President, and Mr. Leonard Horner, Past-President, of the Association, and of Mr. J. S. Holliday, President of the Institute of Builders, and there is also a view of the Council Chamber of the Association at Koh-i-noor House, Kingsway. The volume (including diary) can be obtained, price one shilling net, from Technical Journals, Ltd., Caxton House, Westminster.

The 1912 edition of Sprague's Architects' Pocket Diary contains a new feature in the shape of a complete list of the meetings, members of council and committees, etc., of the various architectural and other societies connected with architecture and

building. The pocket-book includes its usual amount of useful memoranda as to construction and building materials, all comprised within a very small space, and of convenient size for the pocket.

CORRESPONDENCE.

The National Insurance Act.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Having read Mr. Heathcote's letter in your issue of December 30th, perhaps I may be allowed to accept what appears to me to be an opportunity of stating the case from my standpoint—that of a builder.

First of all, I do not object to State insurance. Next, I am already asked under the Workmen's Compensation Act to provide for a man during the period of his incapacitation from work as the result of an accident happening to him whilst carrying out my work. I do not take exception to that; but what I would emphasise is the fact that I am now to be called upon to pay two heavy premiums at once on behalf of a man who can only benefit as a result under the one or the other Act, and not under both.

To illustrate my meaning, let me take figures. Under the Workmen's Compensation Act I am obliged to pay a workman one-half of his average weekly earnings each week during the period of his incapacitation. Prices to-day do not allow me to run this risk. I must therefore cover myself against it, and, to this end, pay a premium of 30s. per cent. on my wages bill to some society to accept it. This means that for every £5,000 I pay in wages my premium against accident to workmen amounts to £75.

Now, take the National Insurance Act. The sum of £5,000 would enable me to employ 55 men for one year. (It is necessary to discriminate; for in the one case premiums are based on wages, and in the other on the number of men employed, and I arrive at the figure by taking the mean of the combined figures of a bricklayer and labourer as a fair average for the trade.) My contribution to the State scheme on behalf of these 55 men at 3d. per man per week would amount to £35 per annum.

Taking, then, the two together, I pay in the aggregate 9½d. per week per man, in premiums comprised as follows: State insurance 3d., and Workmen's Compensation Act, 6½d. But here is the striking part of the whole thing: the workman who is the sole *beneficiare* can only claim his benefits in proportion to and under one of these premiums, notwithstanding the fact that they *both* have to be paid.

It appears to me, then, that one of these Acts is unnecessary, since both are capable of providing very similar benefits, yet one can only be drawn on, though both have to be contributed to.

If some adjustment could be made in the relations of these two Acts, to overcome this difficulty, I personally could and would willingly pay, not only my contribution of 3d., but, in addition, that of each of my men, i.e., 4d., and at the same time save for myself 2½d., or 25 per cent. of premiums; or, on the other hand, and in the event of the continuance of the workman's contribution, increase mine, which, added to that of the State, would enable him to derive greater benefits.

"WINTERGREEN WOOD," PYRFORD, SURREY. CYRIL B. TUBBS AND A. A. MESSER, ARCHITECTS.

The exterior of this house is finished in purple stocks, and the roofs are covered with thick hand-made sand-faced tiles. The external woodwork is in deal painted white. The whole of the interior finishings are of very simple treatment, and most of the woodwork is painted dull white. The house was built by Mr. W. G. Tarrant, of Byfleet, from designs by Messrs. Cyril B. Tubbs and A. A. Messer, of Woking.

SOME UNDERLYING PRINCIPLES OF THE CLASSIC ORDERS.

WITH the exception of the Gothic, there is no period in architectural history in which the order is not one of the fundamental features. There has always been felt the necessity of support other than by the walls, and (writes Mr. Egerton Swartwout) the posts and lintels of the savage have been developed and beautified into the glorious orders of classic times.

Principles Governing the Orders.

It is not the present purpose to trace this origin or development in detail, nor to attempt a modern version of Vignola, but rather to show certain principles that governed the design and the use of these orders; the function of support; the line or curve (Fig. I.) which is the logical expression of this function; the relation of various members of the entablature to each other, and to the column or pier below, and certain other relations, which, though seemingly self-evident, do not appear to have received any attention from authors. The written records of architecture in the classic ages are scanty, nor is it likely that these principles ever would have found a place in literature; they were considered fundamentals, and were handed down orally. They were part of the education of the classic architect, and were added to and corrected until the culmination of the Greek art in the fifth century. From Greece they went to Rome, weakened by the decadence of Greek art in Alexander's time, and while Rome knew them, she did not always apply them. There was great and rapid building in the Roman days, and the architects were not able to give that attention to detail that was demanded in Greece. With the decline of classic architecture, tradition ceased, and when the thread was picked up at the time of the Renaissance, some of the principles entirely escaped the measurements of the restorers who had access only to the Roman monuments. Neither Serlio, Alberti, nor the well-known architect of Vignola give any evidence of appreciation or knowledge of their existence.

Origin and Development of the Column.

The origin of the column came from the necessity of support, and the supporting material in all history, certainly as far as the architectural treatment of the orders is concerned, is lithic. The column, as we find it, is a stone form, and its development has been in that material. The development was gradual, the prototype of the Greek Doric column being in Egypt, although it found little favour with the Egyptians, perhaps on account of its inadaptability to colour decoration. From Asia came the Ionic volutes, and from these two orders the Corinthian was derived, being merely a Doric form with enriched necking of the lotus bell-shape pattern, surmounted with the Ionic volutes. But in all cases the principle was the same, the order being the logical structural development of the post and pier. The early architects had learned that if a column was smaller at the top than at the bottom it had greater stability, and a more pleasing shape, and that if chamfered or fluted it was more decorative. They laid a block on the top of column to provide more support to the beam it

carried, and it became the abacus of the Doric order; and as the transition between the beam and column was unsightly, a moulding was placed between, in the outline of a human hand supporting an overhead weight, not because it was a copy of the hand, but because it gave a pleasing and adequate line of support. The Ionic and the Corinthian orders gave a different shape to this line of support, the Corinthian being extremely logical, but the Ionic unstructural and justifying its use only by its beauty. The Greeks, indeed, seemed to consider it an inferior order for interior and decorative use, and adhered absolutely to the Doric for their great temples, except in the later period of their decadence. But, although unstructural, in the Ionic there is still the same curv-

ing outward of the supporting line in the capital. Beneath the volutes, which form merely a decorated abacus, is the same firmly projecting ovolo as in the Doric order, fulfilling the same purpose, and being such an essential part of the cap that it can never be omitted, nor should it ever be concealed by the side of the volute. (Fig. II.)

Modern Use of the Order.

As in the classic ages the order reached its highest development, so no new

order has been invented since this time; all later orders being developments and variations, successful occasionally, but for the most part unsatisfactory. In the use of the order the usual modern method is either slavishly to copy some classic example without regard to size or location, or to follow the dictum of Vignola, or to invent some hastily studied and ill-worked-out idea, whose only merit is a radical difference from anything that has ever been done before. An order, of course, should, and does in the classic examples, vary according to material, place, and size. No two classic examples are similar, even when designed by the same architect, as may be seen in Ictinus's orders at Phigalia and in the Parthenon; and the elaborate rules of Vignola were merely the ideas of one man. To him all entablatures are one-quarter the height of the column, but in classic days they range from nearly a half at Paestum to nearly one-fifth in the temple of Jupiter Tonans at Rome. The only thing that can be said in favour of the adherence to the rules of Vignola is that the result is generally safe, and, while possibly stiff and wooden, is infinitely preferable to some of the wonderful creations of modern fancy.

The Principle of Support.

But the important feature of all orders is that they are based on the rational realisation of the principle of support. A column should appear to, as well as actually, support its entablature, and the entablature should be big enough to hold down the column. There must be a sense of balance and repose, and the support must be proportioned to the requirement. In an engaged column, for example, where the entablature counts with the building, and the order is merely applied decoration, the entablature can be smaller than that necessary for the same column when free-standing. It was early apparent to the Greeks

that it was not necessary for the supporting member to be the same size as the beam it supported. This was not structurally necessary, as the compressive strength of stone was greater than its tensile strength, and the introduction of the abacus and echinus rendered it unnecessary from an artistic standpoint; so the beam or architrave was then made wider than the upper column diameter, and from the top of the cap the entablature extended outward in an approximation to a curve.

A Great Principle of Design.

This appreciation by the Greeks of the line of support following inward the inclination of the column and then outward by the reverse curve of the echinus to the outer projection of the cornice (see Fig. I) was the great principle by which all of their designs were regulated, a principle which was overlooked in the Renaissance restorations of classic architecture and is generally unconsidered now. The Egyptians in the batter of their walls and the reverse curve of their simple crowning cornice had the same idea, and that idea is naturally inherent; a careful tracing made over a freehand sketch will invariably show the same curve unconsciously made. This curve begins with the echinus of the Doric, or with the necking of the other orders, and extends nearly continuously to the ultimate projection of the cornice,* the only break in the continuity being at the top of the cap, a break which only serves to emphasise the curve itself. This curve or graduated projection of the various faces of the entablature is more apparent in Greek than in Roman work. In the former it is invariable; in the latter it is general but not invariable, if we can trust the restorations. The Roman work has not been as carefully measured as the Greek, and the restorers have been more or less under the influence of Vignola; and as it is very difficult in many cases to tell the exact positions of the different faces from the remaining fragments, it is conceivable that they were restored as the restorers thought they ought to be. In any case, we would not expect the Romans to give as much attention to detail as the Greeks.

An Important and Little Understood Principle.

The most important and least understood principle in this great idea of the Greeks is the relation of the lower face

of the architrave to the upper diameter of the column or to the wall below. It is always in advance of it. In the Doric order so much so that it has always been recognised; the order is intolerable without it. In the early examples the architects were evidently afraid of the strength of the materials; the columns were almost clumsy, and the abaci nearly touched; the architrave stones were of great height and width; but the same general principle obtained. In the Ionic and Corinthian orders the abacus projections are not nearly as great, but the architrave still projects considerably beyond the column face. The projection of architrave beyond plane of wall or beyond anta face is not absolutely universal in Greek work; in one or two cases it is very slightly behind wall face, but these cases are few and are under the shadow of porticos, where the relation is not so apparent; and then, too, the anta cap being very small, there was little or no opportunity for the projection of architrave. In all cases on the exterior

that the author can find the projection is the invariable rule. In some cases the wall is battered and the line of support sweeps out in the reverse curve of the anta cap and the architrave above. The beam is invariably larger than either the pier below or the upper diameter of the column (Fig. VII.). This principle was thoroughly understood in Romanesque and Gothic, as well as in classic work, but was strangely lost sight of in Renaissance days. Vignola and the others, in their treatises on the orders, invariably place the lowest architrave face directly over the upper diameter of the column or over the pilaster face, and it is so usually done now. In the case of the column, the architrave, seen on the angle, projects beyond the upper diameter of the column, and unless the abacus is of great projection the curve is maintained; but in the case of pilasters the effect is most distressing. A row of pilasters seem to be supporting nothing at all, and the great projections of the caps when seen from below, are useless and uneasy, and seriously interfere with the horizontal sweep of the entablature. (Fig. III.)

Relation of Architrave to Column.

There is no rule governing this relation of architrave to column or pilaster. You cannot reduce it to modules or parts. It is as much a part of the design as the proportion of the column or the heights of the entablature. It is governed by the projection of the abacus and by the projection of the pilaster; the greater the projection of the pilaster the less need be the projection of the architrave, the reason for the latter being that when the pilaster has less projection it throws into apparently greater prominence the front portion of the cap; the side of it is scarcely seen, and the architrave face must be extended

to give this front portion of the cap something to support. (Fig. IV.)

■ All the faces of the architrave follow the general out-sweeping curve crowning the line of support. In some instances the faces are vertical and in others slightly tilted forward; in a few cases they are tilted back. But even when they are tilted back the general effect is the same on account of the projections of the faces and of the crown moulding of the architrave.

Frieze and Architrave.

The relation of the frieze to the architrave follows the same rule as that of architrave to column face. It is beyond, or has the appearance of being so. In the Grecian Doric the simplicity of the great architrave seems to unite it with the frieze more than is the case in the other orders, and the triglyphs are on the plane of the architrave face to give this feeling of unity. In a few late examples where they project beyond the architrave face the effect is not so satisfactory. The sculpture in the metopes is in high relief, and projects considerably beyond the architrave face, the outer face of the carving really forming the frieze face. Without this bold relief in the metopes the cornice is apt to look thin and of excessive projection. In Greek, Ionic, or Corinthian the frieze face always projects, that is to say, the apparent frieze face, which is the outer face of the carving; although the background of the carving is usually considerably back of the architrave. In many of the restorations the latter frieze face only is shown, giving an entirely erroneous impression of the orders and causing numberless modern buildings to present a very curious depressed appearance in the frieze. (Fig. V.) The Renaissance architects felt this frieze relation, and usually corrected it by ornamenting the frieze in high relief. In some instances the ornament was not thought sufficient, and recourse was had to corner cartouches, which effectually overcame the difficulty and produced an outline closely approximating the curve. This is very evident in the case of the entablature to the pedestal of the Coleoni statue in Venice. (Fig. VI.) Notice the close approximation to the curve and the valuable points of

light at the top and bottom of the shield caused by the under-cutting in these places.

Corona and Fascia.

The last point affecting the line of the curve is the relation of the corona to the fascia of the cornice. This was always carefully considered in order to avoid a break in the continuity of the line, especially when seen across the corner. This break in the sweep of the curve is very apt to occur at the corner of a pediment (see AB, Fig. VIII.).

The continuity of the curve is noticeable in the anta or pilaster caps. The anta cap was entirely different in character and outline from the column cap; the projection was smaller and the line more flowing, the curve of the cap starting easily and without interruption from the anta face. (Fig. VII.) The same feeling held good in the case of pilaster caps when pilasters were used. In modern days this flowing curve of outline is usually unconsidered. In the Roman Doric order, for example, the pilaster cap is usually made similar to the column cap, and the abrupt line of the ovolo, while necessary and appropriate under the abacus of a column in a pilaster, causes an unpleasant break in the line of the curve and an undue projection of the pilaster cap. The cyma recta or reversa has a much more pleasant outline for such a position than the ovolo, although the shape of the ovolo can be softened so that it can be used. (Fig. VIII.)

Parapet and Wall.

The relation of the parapet or balustrade to the wall below is also worthy of careful study. If elaborately moulded its relation is generally apparent, but if it is a flat surface similar to the wall it never comes directly over the wall face. If it did it would seem part of the wall instead of part of the entablature, and the entablature would seem to the eye to float. It would look as if originally it was at the top of the wall and had slipped down. This feeling would be less apparent if there was a strongly marked cap mould under the cornice, lining up with the cap of an order. In the same way none of the plain surfaces of an archivolt around a door or window should be on the same plane as the wall face adjacent, nor should the plain surfaces of an archivolt be in

the same plane as the wall face or the pier face, and the intrados should be slightly projected beyond the jamb line below.

Centre of Column and Wall Face.

The relation of the centre of a column to the wall face, if it is in antis, is governed solely by the relation of the lower architrave face to the upper diameter of the column, the position of the architrave face being fixed by its relation to the anta cap and to the wall face. If the column is in antis this is easily established, except that sometimes the different projections of the base require delicate adjustment; but where a pilaster occurs, either behind or at the side of the column, the relation is much more complicated. If the pilaster is made the width of the top diameter it is apt to look too thin and slender for the column proportion, and if made the mean width of the column, the pilaster will be wider than the beam it supports. In the location shown in Fig. IX, this difficulty can be overcome by making face A of the pilaster the right width to receive properly the beam overhead and face B slightly wider, so that seen from the front the pilaster will be of proper proportion. Of course, this would be

impossible were the pilaster fluted. In all cases there seems to be no rule. It is a question of design, and varies with the projection and character of the caps.

In fact, in the application of all the principles above described there is no definite rule. The conditions vary, and the design varies; and when once the principles are understood the application becomes at once a matter of taste and study; such study as can be made by careful drawings supplemented wherever possible by large scale models. But in all cases it must be remembered that these variations from what are usually considered the normal relations are very slight. It is like the entasis of a column, very beautiful and appropriate when properly done, giving unperceived a wonderful grace and charm to the shaft, but becoming silly and unmeaning when so apparent that it is readily noticeable.

LONDON'S NEW SCALE

In the streets of the town the point that becomes more emphatic every year is the tremendous increase of scale in our buildings. Anyone can see now that the twentieth century is being marked off quite distinctly from the preceding century. For this, it may be remarked in passing, Mr. Norman Shaw is mainly responsible, but although his Piccadilly Hotel—the most metropolitan thing in London—is the great example, Selfridge's Stores underlined the movement, which has gone steadily on. Basement storeys are roughly rusticated as though hewn from solid rock, or built of large stones clearly articulated; gigantic screens of pillars are connected by constructions of metal, or the windows of two floors are treated as one, giving the effect of huge voids; cornices are exaggerated to mask the small attic storeys; an extraordinary ingenuity is shown to make people look small and buildings big. This, in the opinion of a writer in the "Manchester Guardian," is all for the good—for the main thing about bad buildings is that they have no scale—so long as the grand scale is not used in our narrow city lanes.

In a great thoroughfare like Kingsway Mr. B. Crewe's Hammerstein's Opera House is in its right place, and the lower part, with its powerful effect of rough-hewn blocks like those of the Strozzi Palace, and its small square doors and windows, is very impressive.

At a distance a striking assembly of stone, and at night, when its torches are burning bright, it has a big air of Balzacian romance. Higher up Kingsway on the other side is the little Holy Trinity Church, designed by Messrs. Belcher and Joass. It stands back from the street, forming a curved recess with a door in the centre approached by a semi-circular portico supported by columns. There are two side doors with niches with a decoration of angels in shallow relief. The building is small, but the strong square treatment and the proportion of the parts give a remarkable impression of magnitude. In the same street Messrs. Burnet's Kodak House carries the gigantic screen system a step further, the entire façade being composed of six stone pillars on a two-storey base, united at the top by a heavy cornice, and enclosing five storeys of metal construction.

The best building of the year in London is, the writer in the "Manchester Guardian" thinks, Messrs. Belcher and Joass's Hall of the Royal Society of Medicine in Henrietta Street, near Cavendish Square. The Greek revival that is so strong in Liverpool is clearly making itself felt here, and this bold and refined example stands by itself among our modern work. The effect of the high lower storey is increased by a base of grey granite blocks. The massive doorway shows a lion's head on each side, each holding a massive bay wreath ready to drop on some distinguished doctor's head. The centre part, which slightly projects, as a row of fluted Doric columns, and the windows here in its two storeys are enclosed in a panel, giving the effect of one void. The main decoration is in simple shapes kept flat, suggesting the odd inspiration of a veteran's war medal with four clasps.

Our contemporary further expresses the opinion that the best buildings of the year count among the most notable buildings in London, while the average work stands much higher in conception and detail than that of ten years ago.

CHURCH OF ST. SAVIOUR, LEWISHAM, LONDON, S.E. KELLY AND DICKIE, ARCHITECTS.

COMPETITIONS.

The Swiss National Monument.

A national monument is to be erected by the Swiss. This monument is not to be in Berne, the political capital, but at Schwyz, from which the names of the country and its people (Schweiz, Schweizer) have been taken. The old picturesque town is about 22 miles from Lucerne. A competition (limited to five) was held for the design, and that submitted by E. Zimmermann has been selected. The design provides for a large open space in the foreground (to be used for public festivals), surrounded by rows of trees and adorned with 22 statues. Behind it, on a terrace, a great statue of Liberty is to rise, and behind the statue a building of considerable breadth, but not very high. The wings of the main building will bear bas-reliefs, illustrating the decisive battles of the Swiss wars of Independence—Morgarten and Sempach. The interior will contain spacious halls with niches for sculptures. The mural paintings and those of the ceilings will represent scenes from Swiss history and episodes in Swiss civilisation, while the sculptures in the niches and along the corridors are to be busts and statues of great Swiss men. It is hoped that the main portion will be completed by November 15th, 1915, the 600th anniversary of the battle of Morgarten, but the interior decorations and the statues may not be completed for many years to come.

The Scottish National Memorial to the late King Edward.

A correspondent of the "Scotsman" writes to the effect that since the statement that seven architects had been selected to send in competitive designs for the above, he has been surprised at the apathy shown by the public as to the whole scheme. He adds that the younger members of the architectural profession and young sculptors are sadly put out at such a decision. A competition of this nature is not like one for a public building, when very often the victory is to the strong in staff and to the amount of money spent in getting up showy perspective drawings. In spite of these facts, many of the large open competitions have been won single-handed. Take for instance the recent London County Council Hall competition, won by an outsider, a young man of twenty-nine, and his designs selected by three well-known architects. The correspondent urges that, upon this and several other grounds, this competition ought to be thrown open. If any restriction is made, he says, let the designs be confined to Scottish competitors. He mentions, however, "that the London Memorial is being carried out by a Scottish-Australian sculptor, Bertram Mackennal, along with an English architect—a happy combination of talent."

LIST OF COMPETITIONS OPEN.

JANUARY 29TH, 1912. GOVERNMENT PALACE, MONTEVIDEO.—Designs are invited for a Government Palace and a town improvement scheme. Premiums: For the former, £2,125 and £850; for the latter, £1,060, £640, and £425. Conditions, etc., at the Board of Trade, 73, Basinghall Street, E.C.

JANUARY 31ST, 1912. FEDERAL CAPITAL CITY, AUSTRALIA.—Competitive designs are invited by the Commonwealth of Australia for the laying-out of the Federal

Capital City. Premiums are offered as follows: 1st, £1,750; 2nd, £750; 3rd, £500. Conditions, together with particulars, plans, and instructions, may be obtained at the office of the High Commissioner for Australia, London. Designs must be delivered by January 31st, 1912, to King O'Malley, Minister of State for Home Affairs, Commonwealth of Australia.

[The Institute of Architects of New South Wales and the R.I.B.A. have asked members and Licentiatees not to take part in this competition unless the conditions are made more satisfactory. See our issue for November 8th, p. 485, and article printed in the issue of November 22nd, p. 537.]

FEBRUARY 3RD, 1912. NURSES' HOME, BOLTON INFIRMARY.—Premiums, £30, £20, and £10. Mr. John B. Gass, F.R.I.B.A., has been appointed the assessor.

FEBRUARY 15TH.—NEW PARLIAMENT BUILDINGS, WINNIPEG.—Regulations governing the competition for the new Parliament buildings for the City of Winnipeg may be had from the High Commissioner for Canada, 17, Victoria Street, Westminster.

FEBRUARY 17TH, 1912. NEW OFFICES FOR THE PORT OF LONDON.—The Port of London Authority invite preliminary sketch designs for new head offices in Trinity Square, and for lay-out of a building site. Sir Aston Webb, R.A., is the assessor.

FEBRUARY 17TH. ELEMENTARY SCHOOL, YORK.—The City of York Education Committee invite competitive designs for a public elementary school to be built in Camphesdon Lane, Bishopsthorpe Road. Assessors, Messrs. T. Mellard Reade and Son, Liverpool. Apply, J. H. Mason, secretary, Education Offices, Gifford Street, York.

MARCH 15TH. LAYING OUT ESTATE, PRESTATYN.—Designs for laying-out the Prestatyn Estate are invited. Premiums of £50, £30, and £20. Application (with 19s. 6d. deposit, returnable) was to be sent by January 8th to Lord Aberconway and the Trustees of the Prestatyn Estate, 33, Henrietta Street, Strand, W.C. Designs by March 15th. Judge, Mr. H. V. Lanchester, F.R.I.B.A.

MARCH 16TH. PUBLIC OFFICES, HARROW.—Harrow-on-the-Hill Urban District Council invite designs for enlargement and alterations of their public offices, at a cost not to exceed £4,500. Premiums, thirty, twenty, and fifteen guineas. Plan and instructions (£1, returnable) from Mr. J. Percy Bennetts, Engineer and Surveyor to the Council, Council Offices, Harrow-on-the-Hill. R.I.B.A. will be asked to appoint an assessor.

JULY 1ST, 1912. CITY EXTENSION SCHEME, DUSSELDORF.—Premiums £1,000 and £375. Particulars from the Chief Burgomaster, Dusseldorf.

No date. HOUSING SCHEME, SADDLEWORTH.—The council invite architects to submit designs for houses suitable for the working classes, to be built of stone and in blocks of not more than six, on certain plots of land which have been selected in the district of Saddleworth. The Council will make the following awards: For the first selected designs £25, second £10, third £5. Descriptions of the houses and other information may be obtained on application to E. Rowbotham, Clerk to the Saddleworth Urban District Council, Uppermill, near Oldham.

NEWS ITEMS.

The Licentiateeship.

We are desired to mention that it is absolutely necessary that all applications for election to the class of Licentiatees be in the hands of the Secretary of the Royal Institute by the 30th April, 1912. No further election to the Licentiateeship can take place after June next, but, as it takes some time to examine the applications, it is essential that all the papers be sent in by the 30th April at the very latest.

Partnership Change.

Messrs. Geo. Elkington and Son (George Elkington, F.R.I.B.A., and G. Leonard Elkington, A.R.I.B.A.), architects and surveyors, Norfolk House, 7, Laurence Pountney Hill, Cannon Street, London E.C., announce that they have taken Mr. Hylton B. Elkington, younger son of their senior partner, into partnership as from January 1st, 1912. He is an Associate of the Royal Institute of British Architects, and has for several years held a leading position in the firm's office. The present title of the firm, Geo. Elkington and Son, which has been in use since 1875, will remain unaltered.

Regulation of Stoneware Prices.

A representative of the Association of Stone Ware Manufacturers is reported to have stated to a newspaper representative that it had been rumoured that there had been a combine of the stoneware manufacturers of the kingdom, but this was incorrect. All that had been done by the manufacturers was to enter into an arrangement to do away with undercutting in prices and to regulate the output. The movement in favour of this arrangement had, he said, been under consideration for a considerable time, and it would be no surprise to the building trade. The increase in prices did not apply to the brick trade, but only to pipes and drainage requisites.

Bournemouth Pier Pavilion Scheme.

The Bournemouth County Borough Council gave instructions last week for the preparation of a scheme to provide a pier pavilion at a cost not exceeding £60,000. The site is that of the Belle Vue Hotel, acquired some years ago for this purpose. The previous pavilion scheme, costing £70,000, met with objection at the Local Government Board on account of licensed premises on the ground floor being open to the public without charge for admission. It is proposed in the revived scheme not to abandon the licensing arrangements in the lower part of the building, but to promote a Bill in Parliament to overcome the objection of the Local Government Board.

OUR PLATE.

Roman Catholic Church of St. Saviour, Lewisham, S.E.

This church has a seating capacity for 300, with a choir gallery at the west end. The interior is built in keyed Flettons, and is white-washed. The church has a ceiling of barrel form in six bays, carried on Doric columns of Nailsworth stone. The west front and returns are faced with Dutch bricks and tile bands. The gable projections are of oak, and the roof is of slate. The cost of the church has been £2,400. Messrs. Kelly and Dickie, of London, W., were the architects, and Messrs. F. J. Bradford, of Leicester, the general contractors.

THE CARE OF BOILERS.

THE Factory and Workshop Act, 1901, contains provisions as to the use, maintenance, and periodical examination of boilers used for generating steam in factories and workshops, etc. Buildings in course of construction are included in the category, and altogether the subject is one in which builders may be assumed to take considerable interest. A "Memorandum on Steam Boilers," which has been prepared by Mr. William Buchan, one of H.M. Inspectors of Factories, and published, price 1s. 3d., by H.M. Stationery Office (Wyman and Sons, Ltd., Fetter Lane, E.C.), contains useful observations on causes and prevention of explosions and accidents, dangers peculiar to particular types of land boilers, dangers peculiar to boiler mountings, etc., and dangers peculiar to other appliances, with remarks on responsibility and inspection. There is also a series of seventeen plates, many of which afford useful indications of various defects and dangers of construction or arrangement. The section on the causes and prevention of explosions and accidents may be usefully reproduced.

With regard to boiler explosions generally, Mr. Buchan points out that figures for recent years compare favourably with those for earlier years, notwithstanding the higher pressures at which boilers are now worked, and indicate the beneficial effect of legislation in directing increased attention to the maintenance and examination of steam boilers.

Causes and Prevention of Explosions and Accidents.

The principal causes of explosions are (1) deterioration or corrosion; (2) ignorance or neglect of attendants; (3) water-hammer action; (4) undue working pressure; (5) defective design; (6) defective workmanship; (7) defective material. Deterioration and corrosion cover such causes as: (a) ordinary wear and tear; (b) fatigue of material, caused by constant straining; (c) internal corrosion, due to acidity and other conditions of the feed water; the plates may be evenly reduced throughout, or they may be thinned in parts and unaltered at others, but the commonest form is pitting; (d) grooving due to varying pressures and unequal expansion of the various parts; (e) external corrosion, caused by leakage at seams, faulty connections, or damp brickwork; and (f) overheating, due to scale deposit, grease, or shortness of water.

Wear and tear and fatigue of material can only be provided for by reducing gradually the working pressure of the boiler under expert advice.

Internal Corrosion.

Internal corrosion is sometimes prevented by placing a piece of zinc within the boiler, attached to the affected part, but more often the addition of soda to the feed water is found useful to neutralise acidity of the water; care should be taken, however, not to add too much soda, as corrosion of the brass fittings and foaming or priming—that is, the forcing up of water into the steam space—may result. Other antidotes for internal corrosion are available, but as so much depends on the precise character of the feed water they should only be used on the advice of an expert after an analysis of the water. Some forms of internal

corrosion are slow to yield to any treatment; it is then desirable, if possible, to change the feed water; but if this cannot be done, reliance must be placed upon frequent and careful expert examination of the boiler, and prompt repair or renewal where necessary.

Boilers when not in use are frequently preserved by filling them with water to which a little common soda has been added; this is quite a good practice if there is no fear of the water freezing, and if the water is not of an acid or a corrosive character. Otherwise it is advisable, after cleaning the boiler internally, to keep it dry, by closing it so as to exclude air, and by placing in it trays of quicklime to absorb moisture, the lime being renewed when it becomes slaked.

Grooving.

As grooving is due to the movement of the plates during expansion and contraction, it is important, should this trouble be present, to avoid unnecessary variations in temperature and pressure; the firing should not be forced, and the boiler should be worked under conditions as even as possible. When it does exist, further development must be carefully watched, and repairs executed before danger arises; and if the feed water is corrosive, steps should be taken to neutralise it, as grooving combined with corrosion leads to rapid deterioration.

External Corrosion.

External corrosion, probably the most common form of boiler deterioration, can always be prevented by removing the cause. The entire exterior of the boiler should be kept perfectly dry, leaky seams and faulty connections should be attended to at once, while the boiler covering should be removed periodically and the seating and flue covers should at least be "ploughed"—that is, removed at the seams—from time to time to ensure that no wasting is going on. Neglect of this precaution has been a fruitful source of fatalities. A boiler should be placed, if possible, above the ground and under cover; a damp situation should be avoided, but if this is inevitable a concrete foundation of sufficient thickness should be used.

When serious wasting is discovered, arising from any cause, the plates should be drilled at the affected parts to ascertain the exact thickness; but before measuring them, the burr left by drilling should be removed, or the plate gauged by an approved thickness finder.

Overheating Due to Scale and Sediment.

Feed water often contains solid matter in solution (hard water*) or suspension. As evaporation proceeds, solid matter in solution is deposited as a fine precipitate which, under certain conditions, forms a hard scale or crust. Sea water acts in the same way, leaving a deposit of salt.

* There are two forms of the soap-destroying power known as hardness—(1) temporary hardness, due to the presence of calcium and magnesium carbonates, which are soluble in water containing carbonic acid, and (2) permanent hardness, due to the presence of calcium and magnesium sulphates or other salts soluble in water, irrespectively of the presence of carbonic acid. Temporary hardness cannot be removed by boiling; the carbonic acid is driven off and the carbonates, no longer soluble, are precipitated. Permanent hardness cannot be removed by boiling; the salts are not thrown down, but as evaporation proceeds the solution becomes more and more concentrated until finally saturation is reached and the salts are deposited.

If the feed water is sedimentary—that is, contains solids in suspension—there will be a deposit of mud within the boiler. It is most important to prevent any accumulation, and the remedies may be classified as follows: (1) substitution of a pure water supply; (2) treatment at the boiler; and (3) removal of all scale-forming constituents from the feed water before it enters the boiler. The first remedy, although effectual, is not always practicable, and the second class covers such methods as (a) the systematic cleaning of the boiler and removal of scale; (b) blowing off regularly when the boiler is at work to carry away the deposit and keep the density† below $\frac{2}{3}$, and (c) the addition of a suitable solvent which prevents the deposit forming a hard incrustation. Before using any boiler composition it is expedient to have the water analysed and to settle the routine under expert advice, as a composition suitable with one kind of feed water may be useless with another, and it should be remembered that the use of such composition does not remove the necessity for systematic cleaning.

The most satisfactory way to deal with scale-forming constituents in feed water is to effect their removal before the water enters the boiler. Sediment may be removed by allowing the feed water to settle in ponds or by filtration, while hard waters may be treated by one of the many efficient water-softening plants‡ in the market, and if temporary hardness only has to be dealt with, a considerable portion of the scale may be removed by using one or other of the satisfactory feed-water heaters now obtainable. The use of feed-water heaters and water-softening plants is gradually extending, as they effect considerable economy by increasing the efficiency of the boilers and reducing the work of scaling, and incidentally lessen the risk of explosion from overheating.

A definite interval cannot be fixed for cleaning and scaling boilers, as so much depends on circumstances. For each boiler this interval should be fixed by experience, and the best guide is probably the thickness of deposit, which should not be allowed to exceed a sixteenth of an inch on the main heat-absorbing surfaces; particular attention should consequently be given to the removal of scale from parts exposed to high temperatures—for instance, furnace and firebox crowns and tubes of multi-tubular and water-tube boilers. These tubes can be kept clean by the use of brushes or tube scrapers of various types, and if it should happen that the deposit is hard, turbine cleaners can be applied. The latter are operated by water, steam, or compressed air, supplied by a hose, and the rapid succession of blows by the vibrator or milled cutter knocks the scale from the tubes, leaving them practically clean.

† The density should be regularly ascertained by drawing a small quantity of water from the boiler at a special tap or at the gauge glass drain cock, taking care that the steam cock is closed, and placing in the water a salinometer or hydrometer which consists of a bulb of glass or metal having a graduated stem on the top and a stem below filled with mercury to make it float upright.

‡ In a recent instance the feed water of a certain boiler had 22 degrees of hardness (i.e., parts of carbonate of lime per 10,000) and much trouble was experienced by the deposit of a thick, hard scale after the boiler had been working a month. Since the introduction of a water-softening plant the hardness has been reduced to four degrees and the scale to a deposit of a friable nature barely one-sixteenth of an inch in thickness; the remaining four degrees are not dealt with, as the addition of more soda would introduce trouble in other directions.

As nearly all the explosions of water-tube boilers occur at the tubes it is most important that they be kept clean. Recommendations regarding the cleaning of these tubes will be found on pages 13 and 14 of the Memorandum, under water-tube boilers.

Overheating through Grease.

When exhaust steam is passed into the feed water to heat it, or the oily water of condensation from a condensing engine is used as feed water, grease will be present in the boiler, and as it becomes concentrated on the surface of the flues or tubes, will not only reduce the efficiency of the boiler, but be a positive source of danger, as it may lead to serious overheating and subsequent collapse of furnace crowns or tubes. "A film of grease one-hundredth of an inch thick offers resistance to the passage of heat equal to a steel plate ten inches thick. In other words, grease offers a thousand times the resistance of steel to the passage of heat." If it were only realised that the apparently harmless film of oil offered as much resistance to the passage of heat as a thick deposit of hard scale, more care would be taken to eliminate it. If oil is present in the feed water much of it exists in an emulsified condition—that is, in the form of minute suspended globules. The principal methods now in use for the removal of grease are:—

Filtration of feed water. Whether gravitation or pressure filters are used the feed water passes through some filtering medium such as canvas or sand. In land boilers this system is not advisable, as a rule, except as an auxiliary to other methods (mentioned below), as the filters only remove the bulk of the oil, but not the finest particles of it.

Separation of grease from the exhaust steam before the steam enters the condenser or heater. A grease separator consists of a metal chamber with a number of baffle plates inside. Owing to the large volume of the separator and the presence of the baffle plates, the velocity of the exhaust steam is reduced, and consequently, the bulk of the oil is thrown down. This method gives better results with non-condensing engines than with condensing engines; results are often unsatisfactory with the latter because of the great velocity of the steam as it passes through the separator.

Chemical treatment of the greasy water and subsequent filtration. The feed water is automatically treated with correct proportions of suitable reagents which collect the minute globules in a form suitable for removal by filters of wood fibre or sand.

Electrical treatment of the greasy water and subsequent filtration. The water is allowed to collect in a vat. The passage of an electrical current through the water, by means of metal plates, causes the minute globules to coalesce, and in this form the oil can be efficiently removed by sand filters.

If it is desired to heat the feed water by exhaust steam from which the grease has not been removed, the steam should be conveyed in coils of pipes, and should not upon any account be brought into direct contact with the feed water. Where condensers are used, very satisfactory results can be obtained by combining a grease separator (placed between

the engine and the condenser) with a good chemical or electrical method and subsequent filtration.

Overheating through Shortness of Water.

This has been a fruitful source of explosions. Shortness of water may arise from neglect of the attendant, failure of the water supply, absence or defect of water gauges, feed check valves becoming defective, blow-off cocks leaking, or the boiler may begin unexpectedly to prime. Certain defects of fittings lead to shortness of water, and necessitate such precautions as the provision of fusible plugs and low-water alarms. As shortness of water may arise from so many causes, the attendant should not depend too much on routine in feeding the boiler. He should watch the water level very closely, and should keep the water gauges in order, testing them several times daily. Before firing in the morning, he should invariably see that there is sufficient water in the boiler, and should never depend on the fact that there was plenty the night before.

Definite directions cannot be given as to the best course to follow when a boiler is found to be short of water, as circumstances vary so much, and it is a subject on which there is considerable divergence of opinion. Generally speaking, for ordinary boilers the fire should be immediately smothered with damp ashes, sand, earth, or even small fuel, the damper closed, and the fire door left open to allow the furnace crown to cool, whilst the pressure should be gradually relieved by keeping the engine running, if already in motion, or by carefully easing the safety valve, or by opening either the test tap, if any, or the top and drain taps of the glass water gauge. Some authorities recommend turning on the feed water; though accidents have probably occurred in this way, the practice may be allowed under certain conditions—for example, if the fire cannot be damped down, or there is reason to believe that very little of the furnace-crown is bare, or if the feed pipe extends behind the firebridge. For water-tube boilers, the following suggestions are generally practicable:—

- (1) Where there is no leakage and no sign of overheating, the feed should be started, the dampers closed, and the fire doors left open;
- (2) if the tubes are red or there is leakage, the damper should be closed, damp ashes thrown on the fire, the fire doors left open, and the safety valve eased;
- (3) if there is considerable leakage from the tubes the fire doors should be closed, as there is risk in standing in front of the fires, and the damper should be shut and the safety valve eased.

In nearly all cases, drawing the fire is attended with danger, as the increase of temperature which accompanies the operation may be sufficient to turn the scale and bring about a serious collapse, besides necessitating the presence of the fireman in the danger zone. The foregoing suggestions are made for a crisis which, with careful attention, should never arise, and much must always be left at the time to the discretion of the fireman, who should be prepared beforehand, by study of the instructions issued by the Insurance Companies, to act promptly in such emergency. A boiler that has been short of water should not be used again until it has been examined by an expert and any necessary repairs executed.

Ignorance or Neglect of Attendant.

A comparatively small proportion of the recorded explosions (about 14 per cent.) has been due to ignorance or neglect on the part of attendants. These have arisen from such causes as shortness of water, due to inattention to water gauges, feed valves, or blow-off cocks; overpressure, due to neglect of pressure gauges or alteration of safety-valve loads; or overheating, due to deposit through insufficient use of blow-off cocks or neglect to keep the boiler clean. In some cases, unreasonable demands are made upon boiler attendants—for example, a disastrous explosion occurred through the neglect of an attendant who had been on duty thirty-five hours. A person, however competent, could not be alert, either in mind or body, after such a spell of duty. Again, boiler attendants are sometimes entrusted with the execution of repairs, a practice to be deprecated, but the Board of Trade Reports shows that some very serious explosions would have been prevented if the attendants had, in addition to the performing of their duties of feeding, firing, and cleaning, been taught to take intelligent care of the boilers under their charge, been given precise instructions in these and necessary points, and been encouraged to direct immediate attention to any defects coming under their notice before they became dangerous.

When a boiler (one of a range) is at rest, attendants should be particularly careful not to tamper with valves, as they endanger persons cleaning or executing repairs, if steam or water is allowed to enter from some of the other boilers. It is good practice to hang a conspicuous notice on any valves or dampers that have not to be opened, or to secure them with a chain and padlock. When gas-fired furnaces are under repair the damper should be locked and the key kept by the foreman to prevent the possibility of the gas being turned on. Two men were severely burned in 1908, through neglect of this precaution.

Reference may be made at this point to the danger of back draught or flue-gas explosions to which boiler attendants are exposed by flames bursting from furnace doors. During 1908 no less than 187 men were injured in this way at steam boilers on factory premises. These accidents usually occur when firemen are breaking up banked fires. The unconsumed gases in the flues become ignited, and, upon explosion, escape by the furnace mouth. Few accidents would occur from this cause if attendants made a practice, before breaking up a fire, of opening the damper wide enough to allow a sufficient quantity of air to be drawn through the flues to carry away the unburnt gases, and the fires should not be broken up until this has been done. Another method of removing the unconsumed gases is to maintain sufficient draught by two or more 1 in. holes in the damper plate. In some cases, where flue-gas explosions at boilers and economisers have been frequent, the top or side of the flues has been fitted with explosion flap doors, which open with the force of the explosion and relieve the pressure.

Water-hammer Action.

Admission of steam under pressure into a pipe containing water is liable to set the water in rapid motion. This may also happen, while draining a pipe under steam pressure, by the condensation of the steam caused by its sudden contact with a large surface of comparatively

cold water. In either case the water will usually strike the side of the pipe or any obstruction, such as a valve, sharp bend, or dead end of a pipe, with considerable violence, accompanied by a hammer-like report. Water-hammer has caused the fracture of many stop valves and steam pipes and even a few blow-off valves and pipes. As these accidents are numerous they are classified separately in the Memorandum. They are due to defective design, use of unsuitable material, and neglect of attendants, and involve a careful consideration of such details as stop valves, steam pipes, and blow-off cocks and connections.

Undue Working Pressure.

Apart from disregard of instructions and precautions, explosions from this source have been due to over-estimation of safe working pressure, use of incorrect pressure gauges and overloaded safety valve or valves made fast by dirt, or by water freezing in the escape pipes.

Defective Design.

Many explosions and accidents have been due to defects in design, such as unsupported furnace flues, imperfect staying, want of provision for expansion and contraction, use of lap joints causing subsequent grooving, omission of strengthening rings on manholes and mudholes, use of cast-iron connections instead of steel, and use of unsuitable fittings.

Defective Workmanship.

This has been the cause of many explosions owing to the metal being injured, strained, or fractured in the processes of flanging, dishing, and bending of plates, drifting rivet holes out of line, and by the burning of plates and rivets; careless caulking, defective welding, badly made screwed threads on stays, tubes, and nuts are other forms of bad workmanship.

Defective Material.

Many explosions have been due to the use of laminated, blistered, or burnt plates held together by rivets of inferior quality.

WHO INVENTED PORTLAND CEMENT?

Within recent years it has been persistently stated, generally on or about Mr. I. C. Johnson's birthday, that that gentleman was the inventor of Portland cement. The claim was vehemently denied almost as often as it was made. The claim for Mr. Johnson was again advanced when, on November 30th, 1911, he died at the age of 101; and in commenting on it, we wrote, in our issue of December 6th, that the statement that he was the inventor of Portland cement, "while it might possibly be defended on the ground that Mr. Johnson was a pioneer in the industry, and among the first to effect improvements which put the product upon a commercial basis, seems to ignore the fact that the actual 'discovery' of the material is credibly attributed to one Aspdin." This view, though correct as to the main issue, is subject to modification in the light of certain data that have now been published in the "Cement Age."

The History of the Invention.

These include letters in which Mr. Johnson recalls the history of the invention. It is true, he says, that the name Portland cement is due to Joseph Aspdin, a builder at Wakefield, who, in 1811, made certain experiments. The clay

roads in his district were mended with limestone. Aspdin thought that the roapscrapings would make lime. He found that it did not slake, so he pulverised it, and then found that it set hard. It was not until 1824 that he took out his patent (Specification No. 5,022, October 21st, 1824). Mr. Johnson says that Aspdin failed to manufacture a fully satisfactory product: his "Portland," Mr. Johnson says, "was no more like the cement that is made to-day than chalk is like cheese." On the other hand, Mr. Johnson claimed that, as works manager to Messrs. John Bazley White and Sons, of Swanscombe, in Kent, he produced Portland cement which was shipped to the French Government, whose tests of it were set up as a standard of quality. "I formed a company," Mr. Johnson writes—"I. C. Johnson and Co., Ltd.—made much cement, and supplied the French Government with many thousands of tons for works at Cherbourg, Havre, and other ports, got a gold medal for the excellence of quality, so I can fairly claim to be the first manufacturer of a cement that would pass the tests of the exacting engineers of British and foreign Governments."

An independent account

of the origin of Portland cement was supplied by the well-known chemist Dr. Wilhelm Michaelis, of Berlin, to the "Tonindustrie Zeitung" of March 25th, 1905. Dr. Michaelis then wrote: "For the answering of this question,

Who discovered Portland cement?

it has been a particularly fortunate circumstance that one of the very earliest makers of Portland cement, a contemporary of Joseph Aspdin, is still living—namely, Mr. I. C. Johnson—now in his 95th year, and still mentally and physically vigorous, and that I have been able to discuss with him the history of the evolution of Portland cement in an exhaustive correspondence. The communications of this eye-witness and an exhaustive study of English technical literature, especially that of the first half of last century, have now led to the certainty that the contention that J. Aspdin was the discoverer of the Portland cement cannot be maintained.

An Accidental Discovery.

"According to William Aspdin's statement in English technical journals, which statement has never been contradicted, his father, Joseph Aspdin, produced this cement as early as 1811, but only in 1824 patented the same as Portland cement. Clearly this discovery was an accident. At that time the opinion prevailed that a usable hydraulic lime or cement, for example Parker's Roman cement, should only be moderately burnt, as is the case with white lime; that it should yield a soft powder, which when mixed with water will set quickly and rise at the same time in temperature. All other burned, or clinkered or fused products of burning were discarded as useless, which was quite appropriate in the case of mixtures poor in lime of these days with a proportion of one part by weight of silicate to about 1.2 parts of lime. Fate willed it, however, that upon some one occasion such discarded clinkered pieces (but in this instance also much richer in lime) should be ground and gauged, and that these, although they did not perceptibly rise in temperature, hardened ultimately extremely well, and showed instead of the yellow-brown colour a very pleasing stone-grey. As, however, the Aspdins knew nothing of chemistry, it was very difficult to achieve a result of this kind,

as we know now very well to be the case, for either the mixtures may have been too low, or too high in the proportion of lime, and then on cooling either fell to dust, or yielded a 'blowing' cement, or in case they had been badly mixed, both of these together. The difficulty, therefore, lay herein: To produce a reliable clinkered cement; and in fact it was not until the fifth decade of last century that this difficulty was in some measure overcome.

The Evolution of "Portland."

"We have then to represent the evolution of the matter to ourselves as follows—namely, that Joseph Aspdin experimented from 1811 to 1824, but only by a crude 'rule of thumb' method, and that by 1824 he had come so far that he believed himself able to control the proportions of the mixtures and the burning process completely, and that he then took out the patent. The difficulties, however, continuing to exist, the consequence was that the new cement was not reliable. Failures took place, structures gave way owing to insufficient strength and in consequence of 'blowing.' The Aspdins knew very well, however, how to keep the secret, and so much so that the matter remained in such a degree a secret even to themselves that they were never able completely to master the difficulties. No one was allowed to enter their premises. The workmen even did not know or understand the process, for the master had a hand in the charging of every kiln, strewing between the layers different materials, sulphate of iron, sulphate of copper, bone, ash, iron slag, etc., etc.

Johnson's Experiments.

"In the beginning of the 'forties Mr. I. C. Johnson occupied himself with many experiments with a view to produce the new cement, and having paid considerable attention to practical chemistry was able to do this. Johnson was at that time manager in White's factory at Swanscombe (Kent), and made Frost's cement. He found one day, quite by accident, that overburned, almost fused pieces, which had been discarded as useless, and lain aside after being ground and gauged, hardened slowly but ultimately excellently, and showed a pleasing light grey colour. Closer examination showed that the pieces were distinctly richer in lime than in the ordinary Frost's cement, which was made with two parts by weight of chalk to one part of Medway clay, and burned at 900 to 1,000 C., and the litre weight of which, even with the coarse grinding of those days, amounted to only 0.9 to one kilo. Mixtures richer in lime were now made and harder burned, with a proportion of five parts by weight of chalk to two parts of Medway clay, with burning almost to clinkering; a good cement was thus obtained, and as Johnson was enabled to arrive at a sufficient certainty with regard to the proper proportions in the mixtures it became possible to produce a fairly reliable Portland cement. About 1848, then, the Portland cement manufacture began in England to make progress, but for several years thereafter it was carried on in an empirical manner,—that is, it was carried out by what is in England called 'rule of thumb.' The circumstances alone that the chalk and clay in England is in a high degree regular in quality rendered it possible under such conditions to produce a sufficiently reliable article. Even in the beginning of the 'seventies there was as good as no chemical supervision in the English cement works, and it may be recalled that Dr. Bleibtreu, the founder of the Stettiner

Portland Cement Works (Zulchow), derived his knowledge of the process of manufacture of this cement as a worker in one of the English cement works, and that was in the first half of the 'fifties, and, therefore, 30 years after Joseph Aspdin had taken out his patent."

The Case for Johnson.

"I. C. Johnson, therefore, who had practically studied chemistry, was the first to succeed in producing reliable Portland cement (and in White's works) in such a way that this binding agent found recognition and became generally adopted in the building trade, and him it is we have to thank that the superiority of Portland cement was recognised and worthily acknowledged. I. C. Johnson has earned for himself unquestionable merit in regard to the development of this industry by placing the child so long weakly and helpless on its feet and teaching it how to go, and he can to-day regard with satisfaction the magnificent expansion which the Portland cement trade has obtained throughout the whole world."

The article in the "Cement Age" contains a facsimile reproduction of the subpoena served on Mr. Johnson in the action, in 1855, of George Tallentire Gibson against William Aspdin and Augustus William Ord; Mr. Johnson being summoned as an expert witness as to the character of the kilns, engines, and mills which Mr. Gibson had erected for Aspdin and Ord at Gateshead for the manufacture of Portland cement.

STEEL SPECIFICATIONS.

Lecturing on this subject before the Junior Institution of Engineers, Major H. B. Strange, late R.A., said that it is remarkable what results have been obtained in the past in the manufacture of tool steel without the assistance of analytical chemistry, and, one may also say, with very little idea of the ultimate chemical composition of the material itself. By the combined experience of the maker and user of a tool, steel material of a definite description was always supplied for a definite purpose, whoever was the maker of the steel in the first place. Modern science has done but little to alter the system thus empirically arrived at and nothing whatever to improve the quality of the products, except the addition of elements which 50 years ago were very rare or commercially unknown.

Until quite recently sorting into different tempers or degrees of hardness of the steel produced in the crucible furnace was done by breaking off a piece of the ingot, and depended on the decision of the experienced man, who was guided by the appearance of the fracture, and he was the only judge as to the cause of the defects and of the remedies to be applied by heat treatment; but now physics has assisted us by enabling the arbitrary signs, such as certain colours denoting definite temperatures, to be replaced by definite measurement.

The hardening of steel is far from well understood even at the present day, and there is plenty of scope still for the investigator. In steel for edge tools the manufacturer practically finishes his work when he supplies the bar steel, the actual hardening and tempering of the tool after fashioning to the shape required being done by the toolsmiths themselves.

With regard to mixing drill steel, this is also treated by being actually worked. Here again the user can only satisfy himself of the suitability of the material by making actual tests on the work to which the drill is to be subjected. For testing files, there has been recently introduced a well-known machine for making tests. Files in Russia have been systematically tested for 25 years on specially designed machines, and they arrived at the same conclusions as have now been generally conceded in England, namely, that the results ascertained by automatic mechanical testing are not always even of relative, to say nothing of absolute, value. The system consists in the file being pushed under a pressure of about 30 lbs. over the face of a bar of hard steel one inch square, and the efficiency of the file is determined by the number of cubic inches filed away in a definite number of strokes, or before the file ceases to cut; but here, again, the test bar of one inch which has been used is quite as important a factor in the test as the file itself.

In all testing, either cutting tools, drills or files, it is of primary importance to remember that the material which his tools are to attack is just as important as the material of which the tools are to be made, and that it will frequently pay him well to consult the manufacturer before determining which brand of tool steel, drill or file he will adopt.

In the case of the smaller articles the buyer is a practical man who has spent his life in working with steels of the same type. He seldom changes his source of supply, as the particular idiosyncrasies which pertain to each manufacturer's steels may easily upset his practice, which is mainly based on observation and rule of thumb, carried out over very lengthy periods, sometimes several generations. No slight saving in the price, of a few pence in the pound, would compensate him for the loss incurred in reputation and pocket by making changes unless most thoroughly examined beforehand.

The improvement in steels of this type is not so much in the quality as in the price. Newer mills for rolling, more economical methods of manufacture in each branch, have steadily cut down the initial cost of the steel, and in this way a steady fall in the price of these goods is continuously obtained.

It will be realised that it is not possible to employ very rigid or detailed specifications for steel of this kind. The manufacturing practice varies very little from year to year, depending principally on the skill and personality of the individual

workman and the general closeness of the supervision exercised by the steel maker in seeing that only the very best steel is allowed to leave the works.

In the event of any trouble arising, as it must do from time to time with material which is so far human in its nature in that it is liable to so many diseases, the consumer goes at once to the manufacturer, and they put their heads together with a view to finding out the best cure for the ailment.

Engineers and buyers should be very careful to see, when comparing Continental prices with British, that the inspection they have arranged is identical in every detail, as what may appear to them an omission of no import, may seriously affect the price and render any comparison of prices misleading.

THE WINCHESTER OAK PANELLING.

An interesting sequel has resulted from the publication, in connection with the statement that Wykeham's beautiful chapel at Winchester College is to be panelled again in oak, of the fact that the famous old Grinling Gibbons panelling was granted to a Wykehamist, and that after several vicissitudes it found its way to Hursley Park, near Winchester, where it now adorns the entrance hall of Sir George Cooper's mansion. In the story, which was told in the "Morning Post," it was mentioned that the ancient panelling was begged by a Wykehamist for his own private chapel, but that subsequently he abandoned his project, and sold the woodwork. The Bishop of Worcester now writes:—

"I am the Wykehamist in question. When I was at school I was not learned in art, but I admired the chapel woodwork, especially the screen with its fine pierced panels and the doorway surmounted by its broken pediment and the founder's head and mitre. On returning to the school I was distressed to find this valuable work partly piled in the open air, partly stored in a loft, and partly cut up as a screen for the organ bellows. I therefore asked whether I might acquire it, as my brother and I wished to fit up a disused private chapel in my home in Wiltshire. Thus I possessed it. Subsequently it was found to be too large both in quantity and design for that purpose. Presently others besides myself began to recognise that very fine work had been removed in favour of what, at all events, cannot be described as equally meritorious, and I offered the College the opportunity

The above illustration shows a simple apparatus, invented by Mr. Joseph Rees, of Oxford, for washing sand for reinforced concrete work. Mr. Rees informs us that, by means of a garden hoe, two men can easily wash fifteen tons of sand per day in this appliance.

of having it back. This was refused. Later on I offered it to Bishop Thorold for Farnham Castle, thinking that if it could not be used in the founder's College it might be used in his residence. But Sir Arthur Blomfield would not have it. I then proposed it for St. Paul's Cathedral. Again without result. My next effort to place the woodwork worthily was to offer it again to the College in the hope that it might be used for the Quincentenary Library. Once more it was declined. After these disappointments I began to fear that it would meet with the same fate down in Wiltshire that I had saved it from in Winchester, and that it would perish by neglect. So I informed the Governing Body that I saw no other course than to sell it to someone who would value it, and this proposal met with their assent. I therefore disposed of it for a moderate sum to my friend and neighbour the late Lord Heytesbury. After this I heard no more about it till Dr. Fearon informed me that he had seen it at a dealer's—I think in Cheltenham—who had sold it for a very large sum for Hursley. My whole course from the first was to save a valuable work of art, made more valuable by its associations; and finding that I could not use it as I first intended, my principal hope was to get it back to the old school when the tide turned and its value became recognised. In this I failed, but I did not trouble the public with these details because I did not wish to bring odium on the Governing Body of the day, who had kindly met with my wish to preserve the work in the early years. . . . I am comforted by the reflection that my action saved a fine piece of artistic work, but I should have been happier if I had been more successful, and had lived to see it go back to the place for which it was designed."

ROYAL SANITARY INSTITUTE.

The Forthcoming Congress at York.

A Congress and Exhibition of the Royal Sanitary Institute is to be held at York from July 29th to August 3rd next. The president of the Congress will be the Archbishop of York, and among sectional officers will be the following:—

Sanitary Science and Preventive Medicine: President, Sir Shirley F. Murphy; Recording Secretary, Dr. Charles Porter (Medical Officer of Health, St. Marylebone).

Engineering and Architecture: Mr. J. Walker Smith, M.Inst.C.E. (Chief Engineering Inspector, Local Government Board for Scotland); Recording Secretary, Mr. A. Saxon Snell, F.R.I.B.A.

Industrial Hygiene: President, Sir Thomas Oliver.

Engineers and Surveyors to County and other Sanitary Authorities: President Mr. A. F. Grotorex, M.Inst.C.E. (Borough Engineer and Surveyor, West Bromwich); Recording Secretary, Mr. J. S. Brodie, M.Inst.C.E. (Borough Engineer, Blackpool).

Sanitary Inspectors: President, Mr. T. G. Dee, Westminster; Recording Secretary, Mr. A. E. Drummond (Chief Sanitary Inspector, York).

Change of Address.

Mr. Detmar Blow and Mr. Fernand Billerey have removed their offices from 3, Pall Mall East to 10, Grosvenor Road, Westminster (immediately below the Houses of Parliament).

ENQUIRIES ANSWERED.

The Architect and the Penalty Clause.

A. C. H. writes: "What is the position of an architect in dealing with an account? The variations and additions on the contract are agreed, and there is a time and penalty clause. The architect agrees to allow a certain extension of time in which—in his opinion—the work should be completed, and issues his final certificate. Should he state thereon what extension of time he has allowed? The building owner refuses to pay, and insists on the penalty being paid for the remainder of the time that the work was incomplete."

—It is usual for the architect to decide such a question as this, taking into consideration such circumstances as additional work, strikes, troubles with workmen, bad weather, difficulty in obtaining special fittings, etc. His decision is final and binding upon both parties, and can only be impugned upon proof of fraud or wrongful behaviour upon his part. F.S.I.

Cements for Pointing in Exposed Situations.

E. S. (Dudley) writes: "I propose to use Parian cement for the external pointing to brick facing. The joints are $\frac{1}{2}$ in. wide, and are to be raked out as the work proceeds, and pointed up at completion. Does this cement make a perfectly satisfactory job? The building is in an exposed situation."

—Keene's Parian and other similar "cements" are gypsum plasters, subjected to a chemical process in manufacture to retard their setting properties, in order that they may be worked. Parian is sometimes used for pointing glazed brick dados or faience internally, but all gypsum plasters are more or less soluble, and are accordingly unsuited for external use. A special brand of white Portland cement is made—I believe by Messrs. Skelsey and Co., of Hull; or ordinary Portland cement, mixed one of cement to four of silver sand, with a little powdered whiting may be used. G.

Brick and Stone Pediments in London.

W. H. F. (Bedford) writes: "Please give the names of some buildings in London (fairly central) where I could see a classical pediment with pilasters in brickwork and also in stonework."

—A correct classical pediment and pilasters in brickwork will be difficult to discover, unless on a very small scale—as a window dressing, for instance—the projections possible in brickwork being insufficient for the fully detailed classical cornice. In brick buildings the cornice and pediment of Renaissance times was usually of wood. A fine example by Wren, with cut brick pilasters and entablature, stood formerly in Christchurch Passage, and is now re-erected at Christ's Hospital, Horsham. Stone pediments there are in plenty. The entrance to Middle Temple Lane, Fleet Street, also by Wren, is a good example with pilasters. G.

Owner and "Extraordinary Traffic."

A. P. writes: "What right has a road authority to claim against the building owners for extraordinary traffic after building operations? Is it customary to have a lump sum provided in the bill of quantities for this special purpose, to be paid to the authority by the builder? What is extraordinary traffic on a main road?"

"Extraordinary traffic" is a most elastic term, meaning almost any kind of traffic upon a public highway beyond that of everyday life. In many cases it has been rather unduly pressed by the authorities, and at present the decided cases limiting its incidence are not very clear.

Timber carting is a fertile source of trouble by reason of claims of this kind, and I have even had a claim made for carting stones over one road for the purpose of repairing another road in the same neighbourhood. In large building operations, especially when carting has taken place in bad weather and possibly by the aid of traction engines, considerable damage is often done to the public highways, and it is then not unreasonable that something should be paid (though it may be argued that the new building is adding to the rateable value of the district). I advise you to compromise the matter as soon as possible if any claim has been made upon you. Do not go to a court of law. F.S.I.

Electric Light Plant at a Country House.

A. P. writes: "Are direct-driven dynamos preferable to the belt-driven type in an electric light plant installation at a country house? Is it essential to have two separate storage batteries—one for lighting and one for power, so as to avoid the jump in the light when power is used? If one battery only is used, will a three-cable main obviate the difficulty?"

—Direct-driven dynamos are preferable to belt-driven dynamos only because the combined plant occupies less space. Where this is not of importance, a belt-driven dynamo will be found equally efficient, and cheaper, as it will give the required output at a higher speed, and can therefore be made smaller.

The amount of power likely to be used at a country house should not warrant the necessity for a separate storage battery (in addition to the one used for lighting), in order to avoid a jump in the lights—especially as power is not generally employed at night. Assuming, however, that there is a large proportion of power, and that it is used at night, the three-wire system will diminish the trouble, but is not worth while installing unless the runs are long. In any case it is largely a question of installing plant and mains of sufficient power and margin to meet sudden overloads without a perceptible flicker.

Cork Paint.

A. J. H. (London) writes: "I am troubled with excessive condensation on a thin reinforced concrete roof during the changeable weather. There is a paint used on the 'tube' railways and on ships in which, I think, cork in small lumps, or shavings, is used to counteract this defect. Can you tell me the name of such a paint, or whether the cork is obtained separately and mixed with ordinary paint?"

—I am unaware of any ready-mixed cork paint on the market, and doubt whether such a mixture could be applied by any ordinary methods. Galvanised iron roofs are sometimes painted beneath, and, while tacky, rough-cast with granulated cork, which may be obtained from fruit salesmen, to whom it comes as packing with imported grapes. This absorbent coating is a palliative to the dripping of condensed moisture in such cases.

I know of no instance where such a paint has been applied to reinforced concrete, but presume that it might be similarly effective. Do not forget, however, that paint cannot usually be safely applied to Portland cement work until two years after its execution. A solution of hydrochloric acid and water, applied in two coats with intervals of two days, is said to be the best preparatory measure for painting on cement. X.

Putty Lime in Cement.

QUERIST writes: "I have specified three parts white sand to one part Portland cement for the last coat of stucco work to the external walls of a building, dashed while wet with dry 1/2 in. alabaster spar. Most of the work has proved satisfactory, but in some parts the cement work is not so hard as desired, and there are cracks on the face several inches long, and wide enough to admit a coin edgewise. The builder admits having used a small quantity of Buxton lime (putty) to make the material work easier, and perhaps also to get a whiter effect. Does the addition of this lime injure the setting properties of the cement, and does it account for the cracks? The plasterer says the proportion of putty lime will not exceed 8 to 1, but I have reason to suppose that it would be probably much more than that amount."

—It is a common practice in America for external plastering to be executed with well-haired lime mortar, to which one-third its bulk of Portland cement is added immediately before use for the scratch coat, a similar mixture without the addition of hair being used for the floating, finished afterwards with pebble dash. This is found quite satisfactory. A mixture recommended by the Associated Portland Cement Manufacturers

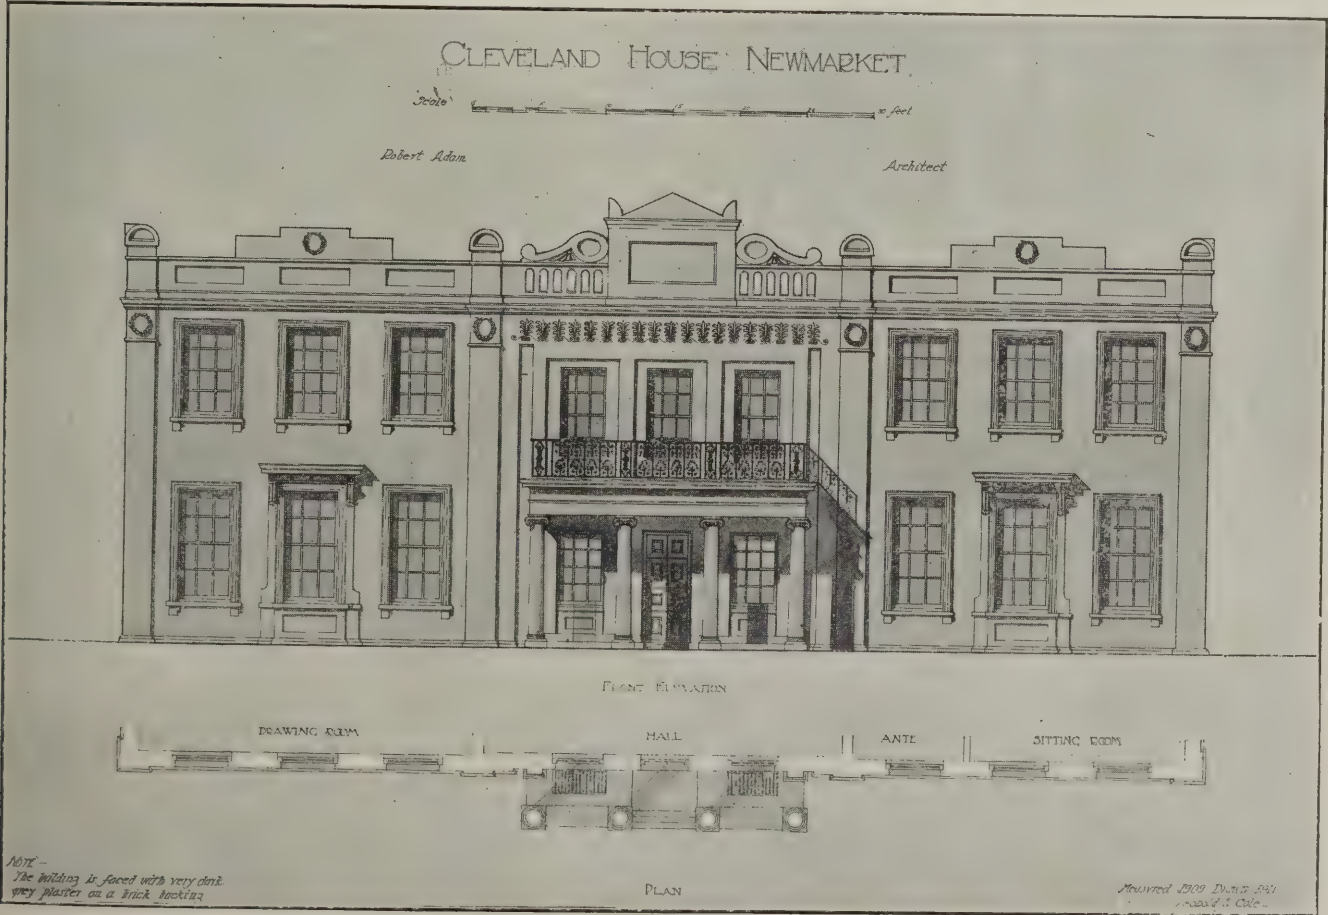

consists of one part Portland cement, four parts clean sand, half-part lime putty; silver sand with a small quantity of powdered whiting being advocated if a white plaster is desired. Shrinkage cracks generally appear in a mortar which is very rich in Portland cement—not less than two parts of sand to one of cement should be used. Too rapid drying (from wind or sun) is a possible cause of the cracking in the case mentioned, or perhaps the cement was dead or had partially set, and had been worked up, for which purpose the lime putty was added. G.

CLEVELAND HOUSE, NEWMARKET.

CLEVELAND HOUSE, NEWMARKET.

Cleveland House was designed by the brothers Robert and John Adam. The date of its erection is between 1762 (when Adam returned from Italy) and 1792 when he died. The house takes its name from its first owner, the Duke of Cleveland, a famous patron of the turf. The present owner is Miss Hammond, of the well-known banking family. Sir Christopher Wren was at one time engaged on the royal palace for Charles II. here, but this is in great part destroyed.

PORTLAND CEMENT ON PUBLIC WORKS.*

By GERALD THORNHILL, Assoc. M. Inst. C.E.

During the last few years there have been many improvements in the manufacture of Portland cement, the most notable being the introduction of rotary kiln burning and fine grinding. These improvements, in addition to cheapening the production, and consequently widening the demand, have introduced new problems for both manufacturer and user.

Not very long ago engineers were content to specify simply that cement used on contracts under their charge must be obtained from an approved firm of manufacturers, and were also further content, when that clause had been fulfilled, to pass any cement the makers cared to send. Nowadays, on public works of any size, every consignment of cement received is thoroughly tested on the works, generally under the almost direct supervision of the resident engineer.

It was the author's intention, in this paper, to enumerate the different tests which should be carried out in order to ensure only perfectly sound cement being used; to explain why such tests are necessary; and, further, to comment generally on the properties and use of Portland cement.

Laboratory of Works.

A cement-testing laboratory should consist preferably of three rooms. One of these must be so constructed that its temperature can, by means of some simple contrivance, such as an oil stove, be so regulated that it never falls below 58 deg. nor rises above 64 deg. Fahr. This room must be absolutely free from all draughts. In it there should be a slate slab on which the cement and water can be mixed, rows of shelves where briquettes and pats may be kept in glass dishes, damp boxes in which newly made pats may be placed, and the initial set testing instrument.

The second room is a small one, and used as an office for writing up the results of tests, checking cement consignments, etc. This room may also contain a slate slab, as it is sometimes convenient to have two gauging tables, but it should be used as seldom as possible. A chest of drawers as a receptacle for specimens showing peculiarities under any test may also find a place here.

The third room should be set apart for carrying out the boiling and all mechanical tests, with the exception of the initial set test, and should contain all the various machines and appliances required for the purpose.

Here, too, the cleaning and greasing of the moulds should be done, and around the room should be shelves for storing the various samples of cement.

Chemical Analysis.

A representative sample from each parcel of, say, 50 or 100 tons, should be analysed, and the result compared with the specified analysis.

The usual proportions of the principal component parts of Portland cement are lime, 62 per cent. to 65 per cent.; silica, 18 per cent. to 20 per cent.; and alumina, 6 per cent. to 8 per cent.

The analysis should not show more than 3 per cent. of magnesia, 2.75 per cent.

of sulphuric anhydride, and 1 per cent. of insoluble residue.

The principal development of recent years has been the increased percentage of lime in the better-class cement. A few years ago 60 per cent. was considered the outside limit, while it is quite common nowadays to find sound cement containing 64 per cent. of lime.

Care should be taken, however, that no more lime is contained than will combine with the silica and alumina present, and the chemical formula for this, given in the British Standard Specification, should be strictly complied with, otherwise free lime will be found in the product.

Some manufacturers vary the percentages of alumina and silica to suit the "set" required; a low percentage of alumina is generally found in a slow-setting cement.

The specific gravity should not be more than 3.25 and not less than 3.15 when the cement is freshly ground.

Fineness.

Modern engineers specify a degree of fineness that would have filled with dismay the manufacturers of twenty years ago.

At that time the usual fineness test was that the cement should pass through a 76 by 76 sieve—that is, one having 5,776 meshes to the square inch, with not more than 10 per cent. residue. At the present time it is quite common to specify not more than 10 per cent. residue on a sieve having 32,400 meshes to the square inch.

The reason for this great improvement in grinding is fairly obvious when one considers the action of water on cement. Water acts only on the surface of each grain of cement; it does not affect the interior of the grain, which always remains inert. Now, a small particle has a greater surface in proportion to its volume than a larger one; consequently, the more finely a cement is ground, the more completely will it combine with water.

Initial Set.

To conduct this test, neat cement is mixed with as much water as will ensure a standard consistency, which can be gauged by a standard plunger; the mixture being filled into a mould resting on glass and then placed in the constant temperature room in a position free from draughts. From time to time the pat must be placed under the needle used for testing the initial set. When this needle fails by its own weight to penetrate to within 3 millimetres of the bottom of the mould, the initial set takes place. The British Standard Specification fixes the initial set as taking place when the needle fails to penetrate to the bottom of the mould. This is not correct in the case of some slow-setting cements, which have a kind of false initial set, as they resist the needle at about 1 millimetre above the bottom of the mould, and remain in that condition for some time, and in some cases for an hour or two. There is no size of mould for this test in general use, but it is most important that a standard size should be adopted. In every case the largest mould has the quickest initial set. Now the larger the mould the nearer the approach to working conditions. Unfortunately, however, the size of mould is limited by the amount of quick-setting cement that a man can handle. It has been found in practice that the best size of mould is

1½ in. deep, 4½ in. diameter at the top, and 4 in. diameter at the bottom, made of ½-in. iron.

Before commencing this test care should be taken that the air, mould, water, and cement are at the same temperature—between 58 deg. and 64 deg. The sample must be exposed in the constant temperature room for 24 hours before testing.

The Vicat needle is the instrument generally used for obtaining the initial set; but some modification of it is undoubtedly necessary, as, owing to the fact that the needle has to be lowered by hand, the personal element is bound to creep into the result. This difficulty is completely overcome by the simple contrivance of attaching a string to the top of the needle and leading it over a couple of pulleys to a small reel. By turning the handle of this reel the needle can be lowered at the same rate and with exactly the same force every time.

Until very recently the initial set has been very much neglected by British engineers, who have been content to specify the limits of the final set only. But the initial set is now being recognised as of primary importance, whilst the final set is quite properly being relegated to a secondary position.

The initial set of any consignment of cement should be regulated according to the conditions under which the cement is to be used. Thus, if an engineer is putting in concrete under water he should order quick-setting cement, and if he is building a dam where the wet concrete is shovelled about, punned, and trampled upon for an hour after mixing, he should order a slow-setting cement. In other words, the time between the gauging and initial set must be longer than the interval necessary to allow of the concrete being placed in its final position.

If there is movement of the cement after the initial set has taken place, the set is liable to be broken, and if it is broken the concrete or mortar will remain soft for a considerable time, and will probably shrink perceptibly when it does get hard.

Shrinkage.

It should be noticed that the mould referred to above is tapered, being 4½ in. diameter at the top and 4 in. diameter at the bottom. The reason for the taper is that, if made so, a test for shrinkage may be carried out with little trouble. The cement is allowed to set for 48 hours, then the glass is removed and two sharp taps with the butt end of a trowel are given to the top of the cement; if the tapping causes cement to project beyond the bottom of the mould, it is obvious that shrinkage has taken place.

There is no shrinkage test mentioned in the British Standard Specification, but it is important, as shrinkage often occurs, and, if not detected, is liable to produce contraction cracks in concrete.

It is readily cured by a few days' aeration—a fact which denotes that the fault is due simply to immaturity of the cement.

Final Set.

It is only necessary to touch lightly on the question of final set, because it is of very little practical use, and also because the method of conducting the test is unscientific and arbitrary. The final set is said to take place when the needle fails to make an impression on the pat, but a mark which is perceptible

*Extracts from a paper read before the Institution of Water Engineers.

to one person may be quite imperceptible to another.

A far better test is to ascertain the pressure necessary to penetrate with a standard drill a standard distance into the block. By this method the time necessary for any cement to attain a standard degree of hardness can be ascertained.

The present final set test gives no idea of the hardness of the sample tested, for if half-a-dozen different cements are tested for hardness at the time of their final set the results will be found to be widely divergent.

Soundness Tests.

The soundness tests are best conducted in the following manner: Take 8 oz. of cement, mix with 26 per cent. of water (rather more if quick-setting), work up quickly into a stiff paste, and divide into four equal portions. Place the first three on pieces of glass and work up with a trowel into smooth round pats, leaving them about half an inch thick. Put one, the "air" pat, in a place free from draughts and of even temperature; the next, the "boiling" pat, into a damp box or humid chamber for forty-eight hours. Allow the third, called the "water" pat, to remain in the air until a skin has formed, then place it in water of a temperature not less than 58 deg. and not more than 64 deg. Fahr.

Take the remaining portion of cement, and, with the addition of a few drops of water, work it up and fill a Le Chatelier mould, then with glasses on the top and bottom, weight it and place in water of the same temperature as the above for forty-eight hours, afterwards boiling it for six hours with the "boiling" pat before mentioned.

"Air" Pat.

After the expiration of forty-eight hours examine this carefully, and if it is wrinkled or shows small hair-like cracks, it will be evidence, in the former case, of shrinkage or contraction of the cement, and, in the latter case, of the presence of free lime. Of late years, since the introduction of scientific methods of manufacture, one rarely meets with a cement so lacking in combining qualities as to show cracks in this test; nevertheless, if they are observed, the presence of free lime will be confirmed by the cracking and warping of the "water" pat, by expansion in the Le Chatelier test of more than four millimetres, and also by signs of disintegration and soddenness in the "boiling" pat.

The evidence of contraction is readily confirmed by the tapered mould already referred to, and by the fact that the Le Chatelier test shows little or no expansion.

If the test is not confirmed in this way, it will generally be found that an unobserved current of air, or the overheating of the room, has brought about too rapid evaporation, and consequently caused the pat to be defective.

"Water" Pat.

After forty-eight hours' immersion the pat should be found to be firmly stuck to the glass at the edges, and no crack or blemish should be visible.

If small and superficial cracks appear at the top or edges, but the pat adheres firmly to the glass and the other tests are satisfactory, it may be safely assumed that the disturbance owes its origin to an undue proportion of the gypsum present in the sample being brought

to the surface in the process of forming and patting.

Some sound cements will not endure in this test the unbalancing of their constituent parts. On the other hand, if the pat is cracked through, warped, or lifted from the glass at the edges, there can be no doubt that the sample is immature. The proof of this lies in the fact that such a sample can always be made perfectly sound and able to pass this test by a simple process of aeration.

"Boiling" Tests.

If there is perfect combination in setting, this pat should dry almost instantaneously on being taken from the boiling water, and have a sharp metallic ring when struck.

On the contrary, if the pat has a sodden appearance, or a network pattern shows as the water dries off, or, worse still, if obvious cracks appear, it is a sure sign of immaturity, and consequently of a lack of perfect combination.

Le Chatelier Test.

If the distance between the points of the mould when measured after boiling is more than four millimetres greater than the measurement before boiling, the cement is probably immature, and this will generally be corroborated by the water and boiling tests. If the expansion is only one millimetre or less it will usually be found that there is perceptible shrinkage in the cement, and confirmation of this must be sought in the tapered ring mould test.

Tensile Tests.

In calculating the strength of any concrete structure engineers assume that concrete offers no resistance at all to tensile stress. On the other hand, the breaking stress of concrete in compression is very important, and enters largely into any problem relating to the safety of the structure.

Yet, the almost universal practice, in drawing up a specification for cement, is to state that briquettes at a certain age shall resist a tensile stress of a certain amount, the theory being that the tensile is closely related to the compressive strength.

Briquettes for tensile tests are made in two forms—namely (1) neat briquettes—that is, neat cement mixed with water only; and (2) sand briquettes, made of one part of cement and three parts of standard sand.

The advent of fine grinding has been the death of the neat tensile test, for it has been established that neat briquettes made from very finely ground cement are weaker at certain ages than the same cement coarsely ground. Such a conclusion is very misleading, and the sand compression tests prove that the neat tensile tests are inaccurate.

Now, with regard to the sand tensile test, Table I. gives the breaking stresses in tension and compression arrived at by a cement manufacturer and three experts whom we will call A, B, C and D,

when testing the same sample. Only the average strength is given in the tables, and this average is obtained by breaking five specimens at each age; the difference between the highest and lowest of the five is in some cases as much as 30 per cent.

A close examination of the averages will reveal the fact that the personal element enters very largely into the making of briquettes. It will be noticed that the difference between A and D at seven days is 27 per cent., and between B and D at twelve months 37 per cent.

Again, comparing the tensile strength with the compressive strength, at seven days old A makes the latter nineteen times as great as the former, whereas D only makes it nine times, and at twelve months old B makes it seventeen times and C only ten times. Moreover, it is impossible to standardise this test, for each sample requires a different percentage of water, and only an expert can tell how much water should be used for any particular cement. Any increase in this amount of water brings about a marked decrease in the initial strength of the hardened specimen.

Taking all these facts into consideration, how can it be argued that the tensile test gives one any idea of the compressive strength of concrete?

Apparently, then, the only reason for continuing the tensile test is that it enables the engineer to form an idea as to how a particular consignment of cement compares in tensile strength with the established standard strength. But even here much depends on the skill of the man who makes the briquettes, for, in the experts' figures referred to above, the difference between two of the averages at seven days is about 30 per cent.

More important than this, however, is the fact that the tensile test altogether fails to reveal a defect that unfortunately appears occasionally in some of the modern cements—namely, the hardening of the outside skin while the interior of the cement remains quite soft. A tensile briquette has a periphery of 4 in., while its cross section is only one square inch, so that, assuming each of the four surfaces hardens, the strength of the briquette will be almost as high as if it had hardened right through.

Some cement of this sort came under the author's observation a few months ago. Pats 4 in. in diameter and 1½ in. thick, made of neat cement, were easily broken with the fingers at twenty-four hours old, the interior of the pats being soft and crumbly, while a thin surface skin was quite hard. The hardening test showed a resistance of only 30 lb. for a penetration of 19 millimetres. An expert's report on this cement showed the initial set to be 2 hours, final set 6½ hours, neat tensile test 3 days, 500 lb., and at 7 days, 700 lb., and sand tensile test at 7 days, 280 lb.

A cement may, therefore, pass the British Standard Specification tests, although it has this very serious defect,

TABLE I.

Name of Tester.	Sand Tensile in lbs. per sq. inch.					Sand Compression in tons per 2½ in. cube.				
	7 days.	28 days.	3 mths.	6 mths.	12 mths.	7 days.	28 days.	3 mths.	6 mths.	12 mths.
A	285	370	410	510	550	18.0	20.4	25.8	28.5	29.0
B	303	338	350	343	380	15.1	21.3	22.0	22.7	22.0
C	356	495	495	560	602	16.8	19.2	21.5	21.3	21.1
D	393	368	492	458	605	11.3	14.1	17.8	20.3	22.5

and it would seem that the only method of detecting it is to bore through a pat, measuring the penetration and the resistance.

This constitutes a test for hardening, which can be conducted after either 24 or 48 hours. The test, being made on a small neat cement pat, is very much accelerated, and the result is comparable with the state of the concrete at about a week old.

An experiment was made to ascertain what relation, if any, there was between the hardening of neat cement and the sand tensile and compression tests at one, two, three, and seven days old. The results may be taken as showing that the hardening compares more closely with the compression test than the tensile test does.

Apparently, then, the only reason why the tensile test should not be superseded by a hardening test is that no standard hardening strength has yet been established, but that is only a minor matter, and can easily be remedied in a very short time.

NORTHERN ARCHITECTURAL ASSOCIATION.

Mr. Henry C. Charlewood on Architectural Topics.

The inaugural address delivered by Mr. Henry C. Charlewood, F.R.I.B.A., as President of the Northern Architectural Association, at Newcastle-on-Tyne, in November last, has now been issued in pamphlet form.

The first portion of the address is mainly occupied with a review of the past year's work of the Association, and of the building topics of the year. During the year, the Corporation of Newcastle, and the Tynemouth Corporation, each co-opted two Association members to act on the Town Planning Committee. Mr. Charlewood regretted that the Corporation of Newcastle had failed to pass their Bill in which a restriction of advertisements was included. Not that advertisements themselves are without artistic merit; the chief objection to them arises from the way in which they are placed. He would suggest that if they are allowed to be placed on the front or even on the gable-end of a building, they should be confined to the limits of certain frames provided for the purpose. In Paris, Brussels, Berlin, and Rome, the advertiser is restricted, and it is to be wished that our own towns will follow their lead.

Mr. Charlewood, remarking that as of late years a good many architects or architectural assistants have been disposed to seek employment in the colonies, it might be of interest to call attention to what is going on in some of them, quoted some interesting information which had been received from an associate who had been in practice in Vancouver for the past three years. From this it appears that architectural practice in Western Canada is much less definitely a profession than in England, for its commercial side is much more evident, and there appears to be no consistent scale of fees. Arrangements for architectural competitions are very primitive, and the history of some of them would show to English architects that with all the defects of the system in England, they are in a comparatively enviable position, for professional assessors are very seldom employed in the Western country. Estimating is done from specifications alone, bills of quantities not being customary; but

sometimes in the case of large public buildings a schedule of prices is prepared at the time of signing the contract. A special difficulty is that of the "lien law," which makes the owner of a building liable for all wages and material claims until the expiration of thirty days after completion, irrespective of what he may have paid to the general contractor on the architect's certificates. This, therefore, makes it necessary for the architect to satisfy himself that all workmen's wages and up-to-date accounts for materials have been paid. Again, the public are very reluctant to employ an architect; and of a list of permits containing 59 sets of plans, only 13 were prepared by architects, owners or contractors being responsible for the rest. Mr. Charlewood's correspondent knew of no town in Canada where architectural assistants were in special demand. Where there has been sudden and rapid expansion, the consequent influx of architects has resulted in some of them working as builders' labourers. In some parts of Australia, Mr. Charlewood said, there appeared to be a great dearth of efficient tradesmen; and he was afraid that in case of a building boom here a similar shortage of labour might be experienced in consequence of large numbers of skilled artisans having been compelled to leave the country during the slack period.

The remainder of Mr. Charlewood's address dealt with the possibilities of steel as what Sir William Richmond had described as "a material that will answer to æsthetic demands"; to the advocacy of covered ways in shopping centres; and to the changes in the requirements for the Institute examinations, which he thought most students would welcome.

NORTHERN COUNTIES FEDERATION OF BUILDING TRADE EMPLOYERS.

The annual general meeting of the Board of Representatives of this Federation was held at the County Hotel, Newcastle-on-Tyne, on December 14th, 1911. Mr. Fred W. Ranken, the retiring president, in the chair, when there were present 40 representatives.

The Secretary reported upon this Federation's suggestions upon the proposed alterations to clauses 20 and 28 of the National Form of Contract and the proposed form of sub-contract. This Federation's observations had been forwarded to the National Federation. The Administrative Committee of the National Federation have considered the reports received from the various County Federations, and have decided to recommend to the annual meeting of the National Federation that the proposed amendments of clauses 20 and 28 be adopted, together with the proposed form of sub-contract.

The secretary presented his annual report which dealt exhaustively with the work of the Federation.

Mr. John Proud (West Hartlepool) was elected president; Mr. W. T. Weir (Newcastle) vice-president; and Mr. J. Guthrie (Darlington) junior vice-president; Messrs. Percy Bray (Middlesbrough) and R. J. Huntley (Sunderland) honorary auditors.

A communication from the National Federation proposing to have set times for the National Conciliation Board to meet to hear appeals, together with the opposing recommendation of the Northern Counties Executive Council, were considered. The recommendation of the Executive Council was adopted.

It was agreed that the National Federation recommendation with respect to the proposed admission of builders' labourers to the conciliation scheme be supported where the builders' labourers are sufficiently organised to justify its adoption.

A report as to the position of the Insurance Bill was given by Mr. John W. White, who said that Mr. Buxton had adopted a great many of the suggestions placed before him by the National Federation in reference to the unemployment section. The Government had been approached to merge the Workmen's Compensation Act in the second portion of the Bill, but had refused to entertain the proposition.

THE NATIONAL INSURANCE ACT.

The Act of Parliament that is easily understood by the laity is indeed a rare and precious document; and the National Insurance Act is of rather more than average complexity, not because its language is specially involved or obscure, but because of its bulk and the multiplicity of its provisions. "During the six months of debate in the House of Commons, no spectacle was more frequent than that of eminent lawyers, and men of higher mental capacity who are not lawyers, confessing inability to understand the meaning and effect of this or that clause or sub-section. And there have been times when the explanations of the Chancellor of the Exchequer or the Law Officers of the Crown have made obscurities of meaning still more obscure. Beyond doubt, the process of amending the original Bill has resulted in greater clarity.

"The worst excesses of the Parliamentary draughtsmen have disappeared. There are, however, still many clauses which would give anyone but a lawyer a headache to read. Few of the fifteen millions of insured persons, and perhaps not all employers and others personally affected by the Act, would disdain a translation of the Act into a plain narrative." It is to this intent that "An Old Parliamentary Hand" has produced "A Full Explanatory Digest" of the National Insurance Act. He has closely followed the phraseology of the Act where that is sufficiently intelligible, but has not hesitated to supply a free paraphrase of involved and technical expressions. The result, so far as we can see, is not, of course, a substitute for the text of the Act, but an excellent guide to the interpretation of its meaning—a text that the ordinary man may read with understanding, and even with interest. The book should have been supplied with an index.

National Insurance Act. A Full Explanatory Digest. By "An Old Parliamentary Hand." William Macdonald and Co., 166, Fleet Street, London, E.C. Pages viii.+72. 7½ ins. by 4½ ins., price 6d.

The Quadriga for Constitution Hill.

One of the first ceremonies which the King is likely to perform on his return from India will be the unveiling of Captain Adrian Jones's bronze quadriga on Burton's Arch, Constitution Hill. The work of erection is now in progress. The quadriga is between 30 ft. and 40 ft. high, and weighs nearly 40 tons. When it is in position the highest point will be 100 ft. from the ground. It is 20 years since Captain Jones first exhibited his design at the Academy. The statuary has been cast at Thames Ditton. Each of the horses weighs five tons, and the mantle of Victory which is flowing in the wind is composed of three tons of bronze.

Volume XXXV.

No. 887.

THE SUSPENSION BRIDGE, CLYDE PLACE, GLASGOW.
DRAWN BY MUIRHEAD BONE.

Mr. Muirhead Bone is unquestionably a great architectural draughtsman. He seizes upon the commonplace and makes it the unusual, as his numerous studies of scaffolding and demolitions abundantly testify. And his rendering being so original and so delightful, it is a pleasure to have fifty such drawings of Glasgow as Messrs. James Maclehoose and Son (61, St. Vincent Street, Glasgow) have recently issued, price two guineas: one of which is reproduced above. The drawings are rendered by photogravure on tinted paper, and will be treasured by all who have an eye to discern the ability and charm they embody.

The above is now in course of erection; it is understood that when it is completed the King will unveil it. The Angel of Peace in her chariot stands on a cannon, and is surrounded by shields, helmets, standards, and other trophies of war. Her right arm is uplifted, her hand bearing a wreath of laurels, while in her left hand is an olive branch. The total height of the group is 32 ft., the total width being 36 ft., which is 10 ft. wider than the base on which the quadriga will stand. The car and the wheels are decorated with the rose, the shamrock, and the thistle, and at the hub is a lion. The total weight of the statuary is forty tons. The horses are double life-size, and weigh six tons each. The work has been cast in the foundry at Thames Ditton, the cost being borne by Lord Michelham, who is making this a gift to the nation.

VOLUME 35. No. 837.

NOTE : The List of Contents will be found on page IV. of the front advertisements.

The Renaissance of Italy, France, and England.

F we do not all learn to understand and appreciate the history and merits and defects of the architecture of the Renaissance period, it will not be for want of books on the subject, and good ones too. Two important treatises on the French Renaissance have recently passed under our notice; now we welcome a third

work, that of Professor Simpson, on the Renaissance in Italy, France, and England.*

As this is the third volume of a series dealing with the development of architecture generally, the subject is of course necessarily treated with less detail than in the books by Mr. Ward and Professor Blomfield, which dealt with French Renaissance only (and the latter only with a portion of its history), and, as it is, the author has had to limit the work by confining it to the Renaissance architecture of three countries—Italy, France, and England—in order to avoid making the volume disproportionately large for the series to which it belongs. But in fact all that is best worth attention in Renaissance architecture is centred in those three countries. German Renaissance is bad wherever it does not merely copy Italian; and Spanish Renaissance is distorted by Moorish traditions of multiplicity of ornament, except where the influence of Herrera and his school chilled it into commonplace. And even of the trio of nations selected it must be admitted that England makes a bad third; but for Inigo Jones and Wren, she would be nowhere. The real history of Renaissance architecture belongs more especially to Italy and France.

The author does not omit to recognise, at the outset, the fact that the Renaissance in Italy was by no means an entire break with architectural tradition; the Classic tradition had always more or less kept its hold on architecture in Italy, and prevented Gothic from ever attaining to that complete and grand unity of style which it developed in France and England; so that in Italy there was really no great Gothic tradition to fight against. And he does not forget to point out to his readers that the Italian Renaissance architects were not mere copyists—they were adapters, and produced a new and original architecture, though based on Classic tradition. And as he observes, the revival of a style does not make it less a "true" style unless it proves unfit for the customs or the climate where it is revived; and this was not the case in Italy; "no unsuitability resulted in a single instance or a single building of the early Renaissance." For England, of course, the position is rather different.

The use made of the columnar order on the early Renaissance buildings was one of the most important points in their design, for the question of its being a "true style" very largely turns on this. The author recognises that Florence was the real originating home of Renaissance architecture; and there, in the early palaces, no thought was present of adopting columns or pilasters as surface ornament. The

Riccardi and Quaratesi palaces, with their great cornices and their ranges of windows in the wall, were as genuine architecture as anything could be. It is really an immense step from these to such a building as the Rucellai, with its rows of equally spaced pilasters on three storeys, although they are but little separated in date. The author hardly emphasises sufficiently the architectural step which was taken when these non-constructural pilasters were introduced by Alberti. It was the beginning of the academical element in Renaissance architecture, and puts the art on a different footing. We may disapprove or condone it, but we ought to feel that it is the introduction of an entirely different principle in the treatment of architecture. This fact should have been insisted on. It is noteworthy that in Rome, even at a considerably later period, the a-stylar treatment was still retained, for the most part, in the architecture of private mansions. The Farnese palace is almost exactly a century later than the Riccardi, but it is almost as simple architecture; columns are used in the loggie of the courtyard, where they support something, not as features on the façade, except for the small colonnettes flanking the windows, and these have a function in supporting the projecting entablatures over the window heads, for each window is set within what is a small separate architectural design. That framing of the windows within an architectural border is the important difference between this and the early Italian palaces. Professor Simpson draws attention to the importance of this distinction. In the early Italian buildings the arches and jambs of the windows are part and parcel of the walling; and he quotes Vasari to

CHATEAU DE BLOIS: CORNICE OF SOUTH SIDE OF COURT.

*"A History of Architectural Development, in three volumes, Vol. III.: the Renaissance in Italy, France, and England." By F. M. Simpson, Architect. London: Longmans, Green and Co., 1911. Price 21s.

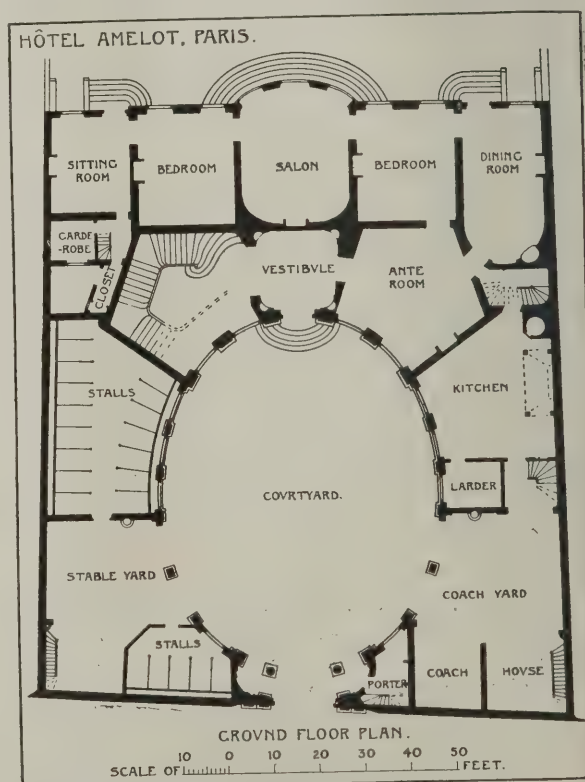

HOTEL D'ASSEZA, TOULOUSE.

the effect that the first building in Florence to which the system of an architectural framework to the windows was applied was the Palazzo Bartolini, designed by Baccio d'Angelo, who was much ridiculed for what was regarded in Florence as a new and eccentric architectural "dodge." We are so accustomed to it now that it is almost difficult to realise how the device would appear to those who saw it as a novelty. The important thing for us is to realise that the treatment of the window with or without a special architectural framework makes an immense difference in the spirit of an architectural design. The window-jamb forming an integral part of the main wall gives the building a more monumental expression, a more *built* look, so to speak; the architectural framework to the windows is a refinement, in a sense, but it is a more artificial way of building; in this respect the Farnese palace looks like the Riccardi type after a century of artificial culture. Which is the better may be a matter of opinion, but the window opened straight out of the main wall makes the more powerful architecture. While speaking of the Florentine palaces, we may note that the author draws attention to the fact that the Pitti palace, as designed and built by Brunelleschi, was not the long comparatively low façade as now appearing, but was only one-third the length, the façade having been extended on each side afterwards by Ammanati, who, however, religiously kept to the original detail. The building has been both over-praised (by Fergusson) and underrated by those who say it is more like a prison than a palace; it is somewhat too stern in its architecture, but certainly impressive for its force and simplicity. What it wants is a great strong cornice, to dominate its rugged masses of wall.

Some remarks on the treatment of windows in the Venetian palaces are worth attention. The author observes that in most Renaissance buildings elsewhere the windows are spaced either equally or irregularly. In Venice they are regular in disposition, but not spaced equally; usually some are grouped closely in the centre, and there are single windows at the side, with a good deal of wall space. Thus, as he says, "the ends frame in the central part, and the angles are strong and solid; the latter an important necessity in all buildings." The want of that, we may observe, is a defect of the Farnese palace façade; the windows come too close up to the angles.

The dome is so important a feature in Renaissance church architecture that it is quite in order to have a chapter devoted to the design and construction of Renaissance domes. The preceding chapter, on the planning of Renaissance churches, shows, in the numerous plans given, how prevalent was the adoption of the type of plan with a wide central space, as opposed to the mediæval plan with its long avenue and narrow crossing. Because the architects wanted domes, the plans must be of a type which would afford both the excuse and the structural abutment for a dome. The church of Monte Santo at Rome, like the Gothic St. Gereon at Cologne, has an elliptical nave with a straight-lined choir added, and deep chapels at the side of the nave, the dividing walls of which act as buttresses. Where the long Latin plan was employed, it was often with a wide centre avenue and a dome at the crossing, as at S. Andrea, Mantua, where the place of the aisles is supplied by a series of chapels divided by internal buttresses. Florence Cathedral, the nave of which is on the mediæval three-aisled model, was enlarged into a great octagon in place of the transepts and crossing, for the sake of an intended dome, or a wide central feature of some kind (for it may be doubted whether a dome was the intention of the original architect, the Renaissance passion for domes not having then developed). In the dome chapter a good many sections of celebrated domes are given. The difficulty always is, with a dome, to make it look equally well internally and externally. A single-cell dome which seems the right proportion internally is almost certain to look too low externally; unless, as at the Pantheon at Rome, and in some modern examples, it is frankly treated externally as a low dome which does not pretend to any soaring character; and a fine composition can be made on that principle, though it can hardly be so impressive as the lofty dome dominating everything else in a city. At S. Maria della Salute the construction is the very simple one of an interior built dome of semicircular internal section, and a timber dome built entirely outside of and unconnected with it, resting on the exterior portion of the walls of the drum. Of the domes in which a more complicated section has been used to solve the problem, the author takes five as special examples—Florence, St. Peters, the Invalides, St. Paul's, and the Panthéon. We should not, however, call the Florence dome one of the complicated examples; it is simply a built dome in two thicknesses, with solid ribs connecting the two

From "A History of Architectural Development."

THE CHATEAU DE BALLEROY.
From "A History of Architectural Development."

shells at intervals, and with a pointed section, in order to give better support to the lantern and less thrust at the base. It would hardly, however, be a stable construction but for the ties introduced, and is not therefore a quite satisfactory specimen of dome building in a constructional sense. It may be added that it is not a dome in the true structural sense, in consequence of its octagonal plan; and it is rather an oversight that no remark is made as to the radical structural difference between this and a true dome. In the dome on a circular plan, each ring of masonry is an arch in a horizontal sense, as soon as it is completed, and it is therefore much easier to erect with safety than a dome on an octagon plan, each face of which is a straight line.

The sections of St. Peter's, St. Paul's, and the Invalides are well known; that of the Panthéon is less familiar; the author states that it is the only triple dome in which all the domes are of stone. The lantern stands partly on the outer dome with some additional support from the middle one. The author describes the construction as daring, "almost foolhardy"; it looks so on the section, but it is not more so than some of the lofty vaults of the mediæval churches. At all events, Soufflot deserves the credit of having chosen to build a monumental dome instead of one with a sham exterior of timber construction. St. Paul's may be a more scientific construction, but it is obtained at the expense of architectural and structural truth.

The author gives a good account of the picturesque early French Renaissance, of which we have heard and read so much lately, and therefore need not enlarge on again. Part of the interest of it lies in the fact that it is so distinctively French. We reproduce the illustration of the cornice of the courtyard at Blois, showing how curiously the French altered the typical form of Italian classical cornice into a detail and proportion of their own. On the other hand, the Hôtel d'Asseza at Toulouse, of the date 1555, which is not much known, is a very charming example of early French Renaissance, showing a much more classic and Italian manner, but still with a character about it which is distinctly French. To the seventeenth century belongs that remarkable example of symmetrical town planning, though on a small scale, at Blois, in laying out the town of Richelieu,

a rebuilding of the village which was the birthplace of the great cardinal of that name, and from which he took his title.

The Château of Balleroy, which was built by the elder Mansard in the first half of the seventeenth century, is interesting as showing how the French, after liberally using the one-storeyed column order in their chateau architecture for a century, seem to have come round to the point at which the Florentine palace architects started—viz., that the order was out of place in a domestic palace, and that effect could be produced sufficiently by walls, window-grouping, and cornice. They added, however, another source of effect of their own, the use of stone quoins at the angles, relieved against a main wall of brick. This produces a very good effect; and the result is a style of building which combines the dignity of Renaissance architecture with a simple and unpretentious character suitable to a private mansion. The author does justice to the architectural genius of the French eighteenth-century architects in producing dignified and effective house planning. The plans of some of these houses, he suggests, are even better worth study than the plans of the Italian palaces; "they are nearer our own time

and our own conditions." The plan of the Hôtel Amelot, at Paris, shows how finely the architect has grouped his plan round the effective lines of a large elliptical courtyard.

It is impossible to turn to the English chapters of the work without feeling how tame and bounded is the English Renaissance architecture compared with that of Italy and France. Inigo Jones's work forms the only exception, and he never got an opportunity worthy of his genius. Even Wren seems rather prosaic in comparison with the Italian and French architects, and the author is justified in his suggestion that possibly, had Wren got to Italy, "actual contact with the ruins of Imperial Rome and the masterpieces of Bramante, Peruzzi, and Michelangelo would probably have given his style that broader bigger touch which to some extent it lacks." The author defends the upper storey of walling at St. Paul's, in which we cannot agree with him. It was an evasion of a difficulty in design, not a solving of it. What strikes one in Wren's work generally is its variety of plan and outline and a certain propriety of treatment which runs through it. But for the most part it wants the quality of greatness and breadth; in this respect Hawksmoor was more of a real architectural genius than his master; but he, like Inigo Jones, never had an adequate opportunity. We are glad to see that the author does justice to the merits of Archer's church at Westminster, a much finer work than is generally realised. Also he has a good word to say for the fine outside stone flights of steps which lead up to the entrance doors of many of the late Renaissance mansions, and for the character of most of the smaller country houses. As he says, "neither outside nor inside is there anything startling about these smaller houses. But they are delightful to live in; their proportions and details are so soothing."

The book is well and liberally illustrated, and especially to be praised for the number and comparatively large scale of the plans given, in which point it contrasts very favourably with some larger and more pretentious foreign works of the same class.

San Clemente, Rome.

SOME consternation has been caused among archaeologists, and we might say among architects also (at least among those who have any interest in the history and development of church architecture), by the news that the twelfth-century basilica church of San Clemente at Rome is in considerable danger from the effects of water in the foundations, and that the attempts to get rid of this by pumping have only proved that water finds its way in nearly as fast as it can be pumped out; and, of course, the installation of a pumping engine in continuous operation is not to be thought of in such a case, though it has been employed in the case of railway tunnels. The proposal now is to make a special tunnel to drain the water away into an ancient low-level *cloaca*, the foundations under San Clemente being lower than any of the municipal drains; one more instance of the tendency of ancient cities to rise in level from century to century. The presence of water in the foundations has prevented their inspection hitherto, and the recent investigation has shown that, even apart from the water, the foundations are not very satisfactory, being of soft tufa; and it seems probable that they will require underpinning and cementing to make the building permanently secure. The immediate need is, however, to drain away the water by the proposed new tunnel drain, which will cost about £3,000, of which amount only one-tenth has yet been subscribed, and it has apparently been decided not to commence the work until the whole sum required has been subscribed. This is prudent, no doubt, from a financial point of view; but those concerned in raising it will look rather foolish in the eyes of the world if the building collapses while they are waiting to collect the funds.

There is no set of buildings in the world more interesting, in a sense, than the basilica churches of Rome; they form the architectural link between the Pagan basilica and the Christian church, and their form of plan, the three (some-

times five) long aisles with the apse at the end, is the germ out of which the plan of the mediæval cathedral was developed. Some of them go back to quite early ages of the Christian church. San Clemente, which was built, or rather rebuilt, at the beginning of the twelfth century (not in the eleventh, as stated in the daily papers), on the site of a more ancient church, is not one of the oldest, but it is one of the finest of its class, containing a great deal of rich mosaic and inlaid marble decoration, and it is one of the few which retain the atrium which was the usual approach to the entrance end of an early Christian basilica church. A little too much has perhaps been made of the other matters of interest supposed to be included in the site, "the Mithraic temple of the second or third century, the subterranean basilica of the fourth century," etc. Ferguson says of it: "The older church has been so altered and ruined by the subsequent rebuildings that it is extremely difficult to make out its history. . . . A considerable quantity of the materials of the old church were used in the new, which tends further to confuse the chronology"; and he throws great doubt on the supposed early date of the frescoes on the walls of the lower church. But the twelfth-century church of San Clemente is valuable enough to justify every effort and expenditure in making it safe, without the enumeration of any adventitious interests.

Roman Research in Italy.

DR. ASHBY'S recent communication on archaeological research in Italy was a good deal occupied with the differences of archaeologists on little points which turn mainly on the interpretation of history. The interest of it for the general reader consisted in the fact that a new ground of exploration has been opened up at Ostia, the ancient seaport of Rome, which is expected to vie in interest with the discoveries at Pompeii. The main street has been unearthed, and the baths, which are described as having fine mosaic pavements. Probably a great deal more will be found there; but the comparison with Pompeii leads one to ask, when is the remainder of Pompeii and Herculaneum, to be uncovered? Owing to the special circumstances connected with their overthrow, by which everything was covered up just as it stood, there is no knowing what remains of ancient art and architecture are still waiting to be discovered there; and the exploration of Herculaneum has been long talked about and written about, and nothing done.

Lambeth Palace Library.

LAMBETH PALACE LIBRARY might, it would appear, receive more attention from architects than it has hitherto accorded it. Apparently it contains many books and documents that could very profitably be consulted by students and historians of the art. This impression is confirmed by notes of some entries in a small pamphlet, reprinted from "Archæologia Cantiana" on "Kentish Annals in Lambeth Library," which has been prepared by Mr. S. W. Kershaw, M.A., F.S.A., who was thirty years' librarian at Lambeth. The library contains about 1,300 volumes of MSS., and it were indeed strange if these were found to contain nothing of architectural interest; and the same may be said of the twenty-volumes of Commonwealth Surveys; while the library is doubt rich in parish registers, visitation returns, leases, and other manuscripts from which, in all probability, the architectural historian might be able to glean much matter of interest that has been possibly overlooked or unappreciated by investigators whose object was not specifically architectural. Probably any architectural student of the Kentish churches would find it well worth while to visit the library of Lambeth Palace. A few promising items from Kershaw's interesting pamphlet may be here noted. "Notitia Parochialis" comprise six volumes of return queries made in 1705, giving interesting details as to parishes and churches at that time, their condition, repair, and sim-

matters. Thirteen volumes of charters and miscellaneous documents contain many references to lands and buildings, and to the repair of sea-walls. A history, in Latin, of the Priory of St. Martin, Dover, up to 1380, looks tempting. There is also an account of the chapel at Bromley College; and a plan and drawing (1698) of the ground on which Greenwich Hospital is built might be worth inspection; while the collection that is being made of prints, drawings, and photographs of ecclesiastical and domestic architecture has been greatly enriched by the gift, in 1892, by Mr. R. C. Hussey, F.S.A., of many illustrations of Kentish antiquities. Mr. Kershaw has done well in drawing attention to a source of information upon these and cognate matters which, it is to be feared, is not so widely appreciated as it should be.

The Question of the Guildford Cottages.

THERE has been quite an extensive newspaper correspondence on the subject of the threatened demolition of six old cottages on the Farnham Road, near Guildford. It appears that a scheme for widening Farnham Road was agreed to a long time ago between the County Council and the Guildford Town Council, and the latter obtained compulsory power to purchase the cottages in question and have served the necessary notices. It seems a pity that the intention to do this was not made public at the time the decision was taken, so that there might have been time for some consideration of the position. But this is the way these things are nearly always done; a decision is taken which would involve the destruction of some old and interesting building, yet it is carefully kept close until the moment of action arrives; then the announcement of the intended demolition is sprung on the public, and objectors are told that their protests come too late, as all the arrangements are made and the authorities cannot stay their hand. "Cannot" generally, it is true, means "will not"; and that is the history of a good many cases of destruction of ancient buildings. We are disposed to think that there may be two sides to the question in this case. Judging from some published illustrations (one of which we are able to reproduce here by courtesy of the "Morning Leader") the cottages in question, though no doubt interest-

the point, and no one seems to have thought of asking it. If they are not, we do not see that they have any claim to stand. Old cottages, however picturesque, cannot be expected to last for ever and to stand in the way of improvements that are wanted. Another question which might be put, and has not been, is whether the widening of the Farnham Road at that point is really a matter, at present, of public or pressing necessity. We have known several cases where buildings of greater historical or architectural value than these cottages were threatened with demolition because the road was too narrow; the case of Croydon Almshouses was one of them; in this and other like cases it has been said that the road must absolutely be widened, that it was quite inadequate for the traffic, and so on; but when it was found that the public opinion on the matter was too strong to be neglected, the authorities gave way, and have found that they could go on very well without widening the road, after all. Public authorities are often very apt to think that a road is too narrow for the traffic, because it is narrower at one place than at others, whereas the fact may be that the other part of the road is wider than necessary. That is another question to be put in the matter; the Town Council may have determined long ago to widen the road there; but had they any good reason for it, or was it merely because the road was narrower at one part than another? Unless there is a real and proved necessity to widen the road, why not leave it alone for the present? The cottages cannot last for ever; and when they become too dilapidated to live in it will be time enough to remove them and to alter the road boundaries.

The dispute on the matter reminds one of the recommendations in the London Traffic Report, which we noticed the other day, that a building line for main roads ought to be determined as soon as possible. We should then know what houses or cottages on a main road would have eventually to be condemned, instead of the disclosure being left to crop up in an unexpected manner, creating differences. And it also suggests a consideration applying to all such cases; that the preservation of ancient houses ought to depend a good deal on their sanitary condition, which is seldom mentioned or thought of. There has been some severe criticism, for instance, on the authorities of Rouen, on account of their avowed wish to pull down and rebuild some of the picturesque old streets of the town; and to people at a distance it seems a most stupid piece of vandalism to suggest it. But walk through those streets, and see the dirty condition of some of these old buildings, with the smells of centuries soaked into them, and it will be difficult to conclude that the city authorities were not in the right in wishing to clear them away. No one loves old and picturesque buildings more than we do; but the health of town and country is even more important than picturesque-ness. Old buildings, after all, cannot last for eternity, and it is possible to worship them to an unreasonable extent.

The London Museum.

ONE of the first results of the attempt to found a museum of London antiquities seems to be, according to a letter in the "Times" by Sir Francis Laking, the keeper of the museum, the discovery, or at least the suspicion, that the history of London as the capital of England is not so continuous as has been supposed. He points out that the finds of Roman remains in London are not nearly so important as those of Colchester and York, and that the conclusion is that there was a considerable period during Roman rule when London was not so important a centre as those two cities. However, this does not in any way lessen the desirability of founding and maintaining a special museum of London antiquities; the history of the city is long enough, and its pre-eminence in later centuries important enough, to render an historical museum of everything connected with it an undertaking of the greatest interest. No one who has been through the contents of the Carnavalet Museum at Paris, where everything bearing on the history of that city is collected and classified, but must have wondered why no similar establishment has been started in London. And when the London

ing as relics of the past, are not very picturesque or interesting otherwise, and we should like to know, before taking sides, whether these cottages are good dwellings in a sanitary sense, wholesome and comfortable to live in. We should be rather inclined to doubt this, judging from the appearance of their exterior; and if they are not, what is the use of prolonging their existence, and leaving them to stand in the way of a public improvement? No correspondent on the subject in the daily papers has said anything about that; we hear only of their appearance externally, and that their removal will take away a certain element in the old-world charm of Guildford. That is no doubt the case; but the question—"Are they healthy dwellings?" is still more to

Museum is once fairly in being and adequately housed, it is to be hoped that one of the first steps to be taken in regard to it will be to extract the magnificent Crace Collection of plans and views of old London from the recesses of the British Museum, and once more to display them all publicly and collectively where the history they embody can be studied by every one. For some two or three years this collection was on open exhibition in the now destroyed galleries on the west side of Exhibition Road, and few studies could be of more interest than to follow out, in this chronological array of maps, the changes and developments of London during the last three and a half centuries. Now the whole collection is buried in the Print Room of the British Museum, where few people but professed archaeologists know of its existence, and even they can only study the contents piecemeal in successive portfolios. There could not be a greater mistake than to hide such a collection from public view; and if, as we presume, an Act of Parliament would be necessary to compel its cession by the British Museum, it would be legislation well employed, provided that the necessary space for its complete exhibition were first secured; for it is in its complete exhibition as a whole that its real value consists. That would mean a great expanse of wall, no doubt, and the possibility of doing it depends upon the building in which the exhibition is finally housed. What the Paris municipality did was to purchase a large ancient mansion (once Madame de Sevigné's) and gradually to acquire land and house property round it, and either erect additional buildings, or throw existing ones into connection with the central building. It may be worth while to consider whether there is any large building in London the original uses of which have so far lapsed that it might be acquired for this purpose. It would be better, of course, to have a new building planned and erected for the purpose, but we should probably have to wait a long time for that.

Carnarvon Castle.

WE hear with some consternation that the Office of Works are contemplating laying their hands on Carnarvon Castle and introducing rebuilding and restoration there. The report may be untrue or exaggerated; we should have difficulty in believing that the Office of Works seriously intended anything that could be called restoration, in view of the prevailing feeling of to-day on that subject; but any such proposals should be decisively resisted. Surely the case of Pierrefonds is warning enough.

The American Institute of Architects.

FROM a leading article in a recent issue of the "American Architect" we gather that there has been some difference of opinion as to the action taken by the committee of the Institute dealing with infractions of the code as to unprofessional practices. We gather that their report, including censure of some members by name who were considered to have been guilty of unprofessional practices, was read in an open session of the recent Convention, at what we presume was practically a public meeting. Such a course certainly seems to argue rather more zeal than discretion. In the first place a man accused of unprofessional practices may have a valid defence; the facts may have been wrongly stated, or he may have an excuse which does not appear on the face of the facts; but the public who get to know that he has been censured by his representative professional body will remember that fact and probably not remember his defence. In the Institute of British Architects any charge of unprofessional conduct that may be brought against a member is considered in private, and the offending member privately communicated with; if he has a sufficient explanation to give he has not then been injured by any public reference to his name. If he continued in his evil courses he might bring the Council to the point of

expelling him from the body, but this, if it came to pass, would probably be done by an announcement that he had ceased to be a member under the provisions of a certain by-law named. In fact, in England we believe anything like a public accusation of a member, if afterwards successfully answered, would give him the right to an action for libel. It is quite right that a representative body should act decisively in rebuking, or if necessary, in punishing unprofessional conduct; but the charge and investigation should at least be kept private in the first instance.

Spoiling the Thames.

THE spread of London means inevitably the Cockneyising of the Thames and the intrusion of the builder and the engineer. It is not many years since Richmond was quite apart from the metropolis, but it now no longer is; and the developments have brought the usual disturbing elements in their train. A great effort was made some years ago to preserve the celebrated view from the Terrace, and the Marble Hill Estate was then saved from the clutches of the builder, and preserved for all time. But a little further up the river a grit company started operations, and have effectually disturbed the peaceful serenity of that portion of the reach. And that is not the whole of the business, for a scheme to cut through the footpath in order to form a channel to a small dock has only quite recently been sent back for reconsideration, and a similar stop has been set against a later scheme for erecting a footbridge—possibly a road bridge—across the river at Twickenham, for the purpose of connecting up with the small village of Ham. With the steady growth of æsthetic perception, and the increasing recognition of the direct and indirect pleasures and profits of urban amenities, the objection to unnecessary "improvements" has now more force than heretofore. Both schemes, in our opinion, are wholly undesirable, and we hope that the opposition now being raised will prevent their ever being carried out.

The Burlington Fine Arts Club.

THE collection of early Venetian paintings at the Burlington Fine Arts Club is intended, we are told, especially to illustrate the works of Giovanni Bellini and his school, which culminated in his great pupil Giorgione. There are, however, three examples of Carlo Crivelli, the most representative artist of the school of Venetian painting which was a legacy of Byzantine art; by far the best of these is that numbered 4, in which the figures are much superior in line and design to the other two; all have the same rich decorative effect in costumes and accessories. In some of the other works of this semi-Byzantine school, by Vivarini and Vittore Crivelli, it is curious to notice the mixture of absolutely realistic festoons of fruit, etc., along with the rigidly conventional style of the rest of the decorative detail, showing that the painters of these pictures had no sort of principle to guide them; they could not see that their own naturalistic details and those of the stiff Byzantine type were utterly incongruous. Of the Giorgione pictures exhibited the largest is the Adoration of the Shepherds, lent by Lord Allendale, which has not been exhibited for many years, but the most beautiful is the small Holy Family picture belonging to Mr. R. H. Benson, which was bought for £5 out of a curiosity shop at Brighton some five-and-twenty years ago. We presume it is genuine; it is at all events beautiful enough to be so. Among the furniture objects exhibited is a seventeenth-century cabinet, supposed to be of Arab manufacture encrusted with pearl shell in a diaper design of scrolls, a very interesting piece of work. Two mahogany arm-chairs with boldly designed strapwork backs, on each side of the fireplace, are also worth the attention of architect who design furniture. The exhibition is not, of course public, but entrance is readily accorded by the Committee to persons interested in art.

WHAT IS WANTED IN THE BUILDING TRADES.—II.

IN the first article, published in our issue for last week, want of professional knowledge was suggested as the probable reason why the building trade has so high a percentage of failures. It was hinted also that the professional qualifications of architects and surveyors and builders were probably hardly adequate to the need of the time.

The interest which is being taken by architects and surveyors in the education and examination of aspirants to those professions, and the way they are seeking ever to extend their powers and to increase their numbers—to the end that ultimately the standing of those professions shall be as well guarded as that of any other profession—shows that the needs of the situation are realised by them.

But it can hardly be said that the movement has yet made itself felt among builders to any extent, although it would seem that the time is ripe for the Institute of Builders to undertake a scheme of development of the professional side for builders, which should complement the forward movement now in progress in the sister professions, so as to enable the master builder to respond adequately to the higher technical and professional requirements which are being demanded of him already and will be still more required in the near future.

As was shown in the first article, want of professional knowledge is probably responsible for most of the evils from which builders suffer; and there can be no question but that the more loyal and high-minded a builder is in the conduct of his business the more injury he is likely to sustain from the heedless and unprincipled competition of men who are ignorant of the principles upon which legitimate competition is based. It would seem high time, therefore, that the best elements of the trade combined to save the situation.

Building a Profession in Germany.

It may prove helpful to the consideration of this question if a short sketch is given of the way the professional standing of builders and architects is recognised and provided for in Germany.

One of the best features of the old guilds was the care they took that no one should enter the businesses of which they were the governing bodies except by the way of apprenticeship, journeymanhood, and mastership, in accordance with the rules relating thereto, and after examination to test the knowledge and ability of the aspirant. With the decay of the guild system these regulations disappeared generally throughout Europe, but the guild spirit seems to have survived in Germany to a greater extent than elsewhere, for in no part of Europe are the profession of the architect and the business of the builder more completely recognised and better prepared for than in Germany. In that country the building trade is regarded as a whole organism, and the right to practise in it is guarded from top to bottom.

Beginning with the architect and the master builder, the law of May 30th, 1908, and October 1st, 1908, provides that:

"The right to bear the title of master in connection with a trade sign which purports practical capacity in building work, in especial the titles of architect and master builder, will be regulated by the Federal Council. Until the regulation of the Federal Council comes into force such a title may only be borne if the State Government has prescribed rules governing the right to bear it, and only by those persons named in such prescription.

"The Federal Council may prescribe further regulations as to the bearing of the title of master in connection with other trades which imply the possession of craftsmanship in those who profess them."

Rules had been prescribed in Saxony in regard to the title of architect in 1903, and, in regard to builders, rules were already prescribed in Wurtemberg conferring the

title of master builder on those who acquitted themselves satisfactorily in the State Building Schools at Stuttgart. Regulations were also prescribed in Sachsen-Altenberg and Reuss in Lauenburg for the protection of the titles of architect and master builder.

In Prussia and the other States of the German Federation such regulations did not then exist, and from the passing of the law of 1908, therefore, the assumption in them of either of the titles of architect or master builder is forbidden under penalty. In the same way the illegal assumption of the title of master in connection with any handicraft trade (e.g., mason, joiner, etc.) is forbidden under penalty.

Prior to the passing of this law, the title of master was regulated in regard to a handicraft trade by the law of 1897, which provided that:—

"The title of master in combination with the sign of a handicraft dare only be assumed by craftsmen if they had acquired the right to train apprentices in their profession and had passed the test examination for mastership."

The law of 1908 modifies this to the effect that the right to train apprentices will henceforth only belong to those who have both passed the master test in their handicraft and attained the age of twenty-four years.

Of course, those who already enjoyed the title of master prior to the passing of the law of 1908 retain the title.

Since 1901 the possession of a test by a guild was not sufficient in itself to confer the right to the title of master of a handicraft: it only conferred the right to call oneself "guild master of such and such a guild."

It will be noted that these regulations related to individual trades, but did not deal with the whole building trade until the law of 1908.

Commenting on the effect of the law of 1908, the Year Book of the German Institute of Builders says:—"The custom by which persons who dare not call themselves master masons or master joiners, and so on, simply call themselves master builder or architect, must now come to an end. The Federated Guild of the German Master Builders can now boldly undertake for itself the duty of having that custom forthwith abolished.

Before proceeding to refer to the master tests and other details of the German system, attention may be drawn to the evidence the older law affords that the right to train apprentices was esteemed to be one worthy to be jealously guarded, and not lightly conferred. Probably this was done by the State in the interest of the apprentice, but it must have been based upon a desire on the part of masters to have apprentices.

Compare this feeling with the indifference in this country in regard to apprentices, and one can hardly escape the suspicion that this may be the cause of our backwardness in technical training as compared with Germany.

(Concluding article will appear next week.)

With reference to last week's article on this subject, we have received the following communication from a prominent London master builder who prefers to remain anonymous:—

My views on this subject are as follows: What is wanted in the building trade is very clear. It is *builders*, and not scheming financial agents. Many large buildings are now carried out by *agents* calling themselves *builders*, sub-letting everything, and owning no yard or plant. Some builders have been supplanted by these agents. Some builders (and good ones, too) have become agents themselves.

It is not the builder that requires education—it is the public; for, living in the days of shoddy as we do, as long as a building is slapped up quickly, and with plenty of glue and varnish, the public (not the architect) are quite satisfied, for they know no better.

In my opinion the following may save the trade from the distressing way in which it is now carried on. The architect should insist that everything possible should be done by the builder, by his own men on the job and at his works. He should not nominate sub-contractors, neither should he allow the builder to employ any.

The old system of apprenticeship should be reverted to

The officials of the men's unions and the officials of the Workshop Act should pay more attention to those making goods for buildings, for many of the latter sweat their men and allow them to work in unhealthy and dangerous premises.

PARIS APARTMENT HOUSES.

LONDONERS, if they can help it, do not live in the midst of their business; they regard the metropolis as a wonderful place to work in, but one nevertheless which it is highly desirable to get out of after business hours. Hence the general exodus every evening to the suburbs, where the bulk of people desire to have a small house. Parisians, on the contrary, belong to Paris, body and soul; they love to work in it and to find their recreation in the midst of it; and as the small house is, for obvious reasons, an impossibility in such surroundings, there have arisen the thousands of apartment houses, each embracing its complement of flats. One might expect to find, therefore, the ideal flat in Paris, but to do so it is first necessary to be a Parisian, with a Parisian's taste and outlook; and in studying a few plans of such buildings, it is well therefore to forget that there are some things which our Building Acts would never allow, but which are taken as a matter of course in Paris; as, for example, the enclosed w.c., with no window, or with one opening on to the interior of the house.

As an example, we may offer the apartment house completed not long ago at the corner of the Rue Grenelle and the Rue St. Simon from designs by M. Deglane, who is well known as patron of an atelier, and especially as architect of the Grand Palais. This block of flats is situated in the midst of the severely aristocratic Faubourg St. Germain, the quarter occupied by the exclusive families of the old French nobility. The streets here are narrow, and

the forecourts enclosed by high walls and massive doors, beyond which rise façades so dignified as to be almost forbidding. Classic old friends from César Daly greet us on every hand, and a sense of well-being, of quiet and repose, stamps the region as one of true refinement. The financial condition of many of the younger branches of these old families, however, does not permit them to occupy their old houses, though their social life demands that they remain in the neighbourhood. They can only afford a moderate rent, yet their taste and training demand a certain restrained luxury of architectural treatment. M. Deglane's problem, therefore, was to fulfil such requirements on a corner site measuring 75 ft. by 45 ft., and he has solved it by arranging two suites, each of six rooms, on every floor. The plan, granting the habits of French family life, is well arranged, and the available space ingeniously disposed; it is, indeed, exceptional from the French standpoint, by reason of the fact that there is a bath-room provided in each suite, and even a w.c. divided off from the bath-room, though, as indicated above, the placing of this is hardly in keeping with English practice. The "toilettes" serve as dressing-rooms. The staircases entrance and vestibule come in the middle of the south side, the concierge's rooms being arranged to the right of the stairs, and the rest of the space on either side of the entrance being utilised, in the manner customary (even in some of the most expensive Parisian apartment houses) by small shops.

Turning to the exterior, we find material for admiration and also for reflection. The ground-floor storey is carried out in a good hard white limestone, as also the sills and course

above, while for the carved portions a warm buff limestone is used. The brickwork is red in colour, the bricks being laid Flemish bond in white mortar with well-raked joints; except on the top storey, where red mortar has been employed. On the whole we are impressed by the dignity of the building, which, with its bow windows at the corner, carried up through five floors, is satisfying. Yet, though it is the work of an architect of such repute as M. Deglane, we cannot help being astonished at such vagaries as the carved heads below the window sills, the swelling corbels, the exuberance of the carving and ironwork, which exhibits a freedom associated with *art nouveau* rather than with the architecture of a country which boasts the traditions of the Ecole des Beaux-Arts. It is to be noted also how the design seems to go to pieces at roof-level, a defect frequently the case in modern French work even in buildings which are really admirable in the lower storeys. It is expected of us always to be ready with eulogy when French civic architecture is mentioned, but a keen perception of faults in our own work forces on our attention faults like those we have noticed above. That modern French architecture is based on sound tradition, and that Paris offers us abundance of good examples, we do not deny, but all the buildings are not by any means perfect, and it is as well to comment on their deficiencies.

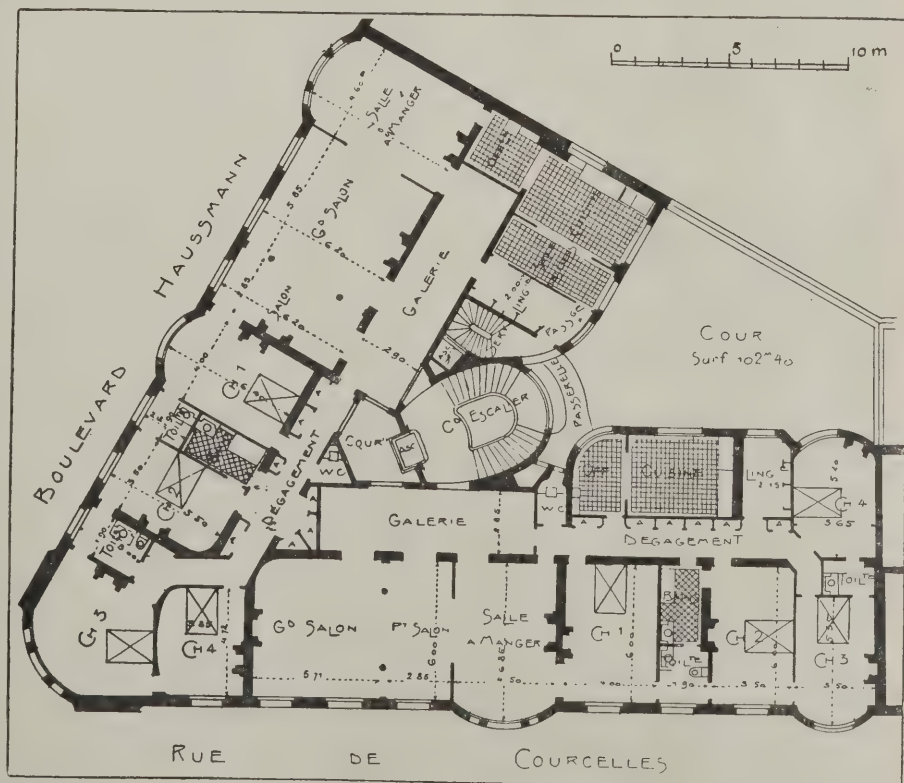

Similar observations might be made in the case of another Paris apartment house here illustrated, that at the corner of the Place St.-Ferdinand and the Rue Brunel, by M. Dupont. This building, however, is more in what is usually considered to be the modern French Classic manner; it is, indeed, a very well-designed building, and planned with great care. In Paris it has become customary to monopolise the best position for the reception-rooms, to the detriment of the bedrooms, thus rendering these comfortless in the daytime. M. Dupont has broken with this bad habit, and, profiting by the shape of the site, has arranged his rooms admirably. The bedrooms, of which there are three in each flat, all face on to the Place St.-Ferdinand, and the drawing-room and morning-room both overlook the Rue Brunel, whilst the dining-room, which is the least used, is lighted from the area at the rear. A large hall connects the front staircase, the dining-room, drawing-room, morning-room, bedrooms, and pantry, the last-named forming the connection between the dining-room and the kitchen. Each flat has a bathroom, two w.c.'s, a back staircase, lift, and parcel lift. The position of the main staircase has been placed where it is, next the party wall, in accordance with the desires of the owner, as it is possible that another building will be added on this side, and the staircase would then be central.

APARTMENT HOUSE, PLACE ST.-FERDINAND AND RUE
BRUNEL, PARIS: TYPICAL FLOOR PLAN.

H. DUPONT, ARCHITECT.

As a third example, and an excellent one, we give as the Centre Plate in this issue the apartment house at the corner of the Boulevard Haussmann and the Rue de Courcelles, Paris, which illustration we reproduce from our contemporary "L'Architecte." This building, faced with stone, is a very good specimen of the best modern architecture in Paris, and the architect, M. Lefebvre, is to be congratulated on the result he has achieved. It masses up well, the dome at the corner being especially successful in treatment, and the details throughout—in the ironwork balustrades and the stone carving—most refined.

R.I.B.A. EXAMINATIONS.

The Final: Alternative Scheme of Testimonies of Study.

The alternative Scheme of Testimonies of Study for the Final Examination will come into operation at the option of the candidates in November next, and after the end of the year 1913 the existing Testimonies of Study for this Examination will be abolished. Six alternative Problems in Design will be set by the Board of Architectural Education each year, and candidates for the Final Examination must submit designs in answer to at least four of these Problems. These alternative problems will be published twice a year, three sets in *January* and three in *July*. This is done for the convenience of candidates, but it must be distinctly understood that the time for sending in the designs in answer to these problems is strictly limited. Thus the designs for Subject I. must be sent in to the Secretary R.I.B.A. or to the Secretary of the Allied Society for the district in which the candidate is working by 29th February, 1912; those for Subject II. by 30th April, and those for Subject III. by 30th June. (This time will be extended for students in the Colonies; see dates following list of subjects below.)

The drawings to be on imperial sheets.

The Subjects for the first half of the year 1912 are as follows:—

Subject I.

(a) A large Monument, to commemorate King Alfred's refounding of London one thousand years ago, for a public place in the City, not to cover more than 500 superficial feet.

All drawings to be $\frac{1}{2}$ inch scale and shaded.

(b) A Terrace of Five Houses 20 feet frontage, each six storeys high, including basement, facing the parade of a small watering place. Detailed construction of one house to be given and a design for the complete terrace.

Drawings required to be $\frac{1}{8}$ inch and $\frac{1}{2}$ inch scale.

Subject II.

(a) A large Monument to an Explorer, to be placed against the wall of a public building.

Shaded drawings required to be $\frac{1}{2}$ inch scale.

(b) A Cloister with external entrance gateway or tower to a collegiate building round a courtyard 100 feet square.

Drawings to be $\frac{1}{8}$ inch scale, with $\frac{1}{2}$ inch details of the complete construction of one bay.

Subject III.

(a) A Detached Ballroom to a large country house, to be connected with the house by a covered way. The decorations should be specially considered.

Shaded drawings to $\frac{1}{2}$ inch scale showing both interior and exterior, and a detail of decorations.

(b) A Landing Stage to a river or lake with a restaurant.

Drawings to show complete construction $\frac{1}{8}$ inch scale and $\frac{1}{2}$ inch.

Dates for Submission of Designs in 1912.

	Subject I.	Subject II.	Subject III.

The Subject of Construction and Shoring: Memorandum to Masters of Architectural Schools.

The Board of Architectural Education have received a communication from the

examiners to the effect that many of the candidates at recent examinations have shown weakness in the subject of construction generally, and shoring in particular. They would therefore direct the attention of the masters of the architectural schools to the importance of impressing on their students the necessity of studying more carefully this important branch of architectural education.

SOUTHWARK CATHEDRAL.

A committee is being formed to consider, and, if possible, carry out, the suggestion that the warehouses and other buildings blocking the view of Southwark Cathedral from the river should be swept away to make room for an embankment and public garden. Mr. Henderson-Livesey's letter, in which the suggestion was originally made, has been warmly endorsed by the Bishop of Southwark, and also by Archdeacon Taylor. The Bishop has now consented to take the chairmanship of the committee.

The land and buildings lying north of the Cathedral and fronting on the river are assessed at £9,428. Including the bank and hotel and offices fronting on the approach to London Bridge, the total is £13,995, or, in round figures, £14,000. At 30 years' purchase, with 10 per cent. added for compulsory expropriation, the price would come to about £462,000, or £311,124 without the buildings on the bridge approach. Another large sum would have to be added as compensation to the dispossessed traders. The actual cost of clearing the site and building the embankment would be small by comparison. But this whole question of cost will, of course, be gone into thoroughly by the committee at the outset.

LONDON'S ROMAN ROADS.

Mr. Reginald A. Smith, of the British Museum, in a lecture delivered last week to the members of the British Archaeological Association on "The Roman Roads Through London," said that he had to advance the propositions that the Romans buried their dead (sometimes after cremation) by preference along their main roads, and that they were great road builders, preferring straight lines shown by fire signals at night. In London the course of Roman streets did not agree with any that we knew now, and he had given up almost as hopeless the task of attempting to trace them. The archaeologists took no notice of the burials, which were the key to the whole position.

One of these Roman roads crossed Shooter's Hill, grazed the river at Deptford, and shot across the Thames at Westminster to Hyde Park Corner. Another Roman way ran down Edgware Road, and joined the line at Hyde Park Corner, which he believed to have been a milestone in our history for generations. There was another line from Edmonton, which crossed between the Tower and the modern Customs House; while yet another came from Stratford and Old Ford to Holborn Bridge. There was also a road starting from the present site of King William's statue, and proceeding by way of Ludgate Hill to Hyde Park Corner, and thence to Brentford, where Julius Cæsar crossed the Thames at the first piece of gravel bottom in the river.

Along these routes there had been found many signs of Roman burials. One of these burial places was under Messrs.

W. H. Smith's premises in the Strand, another under the steps of St. Martin's-in-the-Fields, and another where the statue of King George III. stood in Cockspur Street. On modern evidence, he could not be accused of absurdity if he said that there was a ford at London Bridge. The bridge at Westminster was the objective of the road called Watling Street, in Kent, and there were signs of burials on this route also.

Until 1822 there was visible near the Marble Arch a stone where deserters from the Army were shot. It was their privilege to be put to death just inside the Park wall, but ordinary criminals were hanged at Tyburn. This stone, he believed, was a Roman milestone, which marked the crossing of two Roman roads. It corresponded with the London Stone in Cannon Street; it also stood at the angle of two Roman roads. A space of 155 acres in the centre of Roman London showed no traces of burials whatever. This camp was the first London resting place for soldiers marching to the front, and when they ceased to do so it was taken over by the civil population.

ENQUIRIES ANSWERED.

The Architect and the Penalty Clause.

With reference to the enquiry of A. C. H., in last week's issue of the "Architects' and Builders' Journal," as it is apparent that the question of the extension of time is only being dealt with by the architect at the time of settling the accounts for the completed work, it is highly probable that the penalty clause is thereby rendered null and void; see the recent arbitration case of Porteous v. the Trustees of Saltburn New Primitive Methodist Church and Schools, where Mr. John Simpson, F.R.I.B.A., was the arbitrator, and the decision went in favour of the builder, who was resisting a claim for penalty for non-completion within the stipulated time. Copies of a pamphlet containing the arguments may be obtained from Messrs. Ritson and Hope, 14, Noriolk Street, Sunderland. The arguments are too long to cite here, but one of the grounds of defence alleged by the builder was that the architect not having made an extension of time according to the contract, it could no longer be in his power to say, after the completion, whether the builder should have had more or less time within which to complete his job.

MEMORIAL DRINKING FOUNTAIN,
WALLSEND-ON-TYNE.

The design for a memorial drinking fountain in a public park at Wallsend-on-Tyne, illustrated on the opposite page, by Messrs. Simpson and Lawson architects, of Newcastle, was selected in the recent competition which was instituted among local architects. The memorial is to be erected to the memory of the late Ald. Joseph Duffy, ex-Mayor of Wallsend, and embodies a granite drinking fountain with inscription panels and drinking bowls on two sides, and a circular lily pond at each side which would be fed by the waste from the drinking fountain. Circular ornamental flower beds with grass borders may, however, be substituted for the ponds. It is proposed to construct the fountain proper of red granite, with the wing walls of red Closeburn stone, the decorations and fitting being of bronze. The inscription panel and drinking bowls would be polished.

SELECTED DESIGN. SIMPSON AND LAWSON, ARCHITECTS.

THE ARCHITECTURAL ASSOCIATION.

Visit to St. Paul's High School for Girls.

The first of the spring visits arranged by the Architectural Association for this year took place on Saturday, January 5th, when, in spite of the rain, many members availed themselves of the opportunity to visit the St. Paul's High School for Girls, at Brook Green, Hammersmith, designed by Mr. Gerald C. Horsley, F.R.I.B.A.

Mr. Horsley himself was present, and accompanied the members round the building. He also provided a set of working drawings and many photographs of the building, all of which were shown in the central hall.

The school, which was built in 1901-2, was erected for the governors of the St. Paul's School for Boys, which was founded by Dean Colet in the sixteenth century.

The new school was designed to accommodate at least 400 students, and is of the secondary school type of high school.

The main portion of the building has a basement, ground, first, and top floor, and extending on either side are the science wing and the library wing, with a

basement and ground floor only. The school is an example of the modern system of school planning, the class-rooms opening out of a central hall, while corridor and passage space is, as far as possible, economised.

The main entrance is not used by the students, who have a separate entrance in the basement on the west side of the building, with cloak-rooms and lavatories adjoining. The dining hall, covered playground for use in wet weather, caretaker's rooms, swimming bath, and gymnasium are in the basement also. The gymnasium, which is at the south-east corner of the site, has a floor level several feet below the remainder of the basement, to prevent the roof from obstructing the light of the class-rooms in the main building. On the ground floor level at the north end there is a gallery for the use of spectators at displays.

The swimming bath is at the south-west corner of the site, and was erected to the designs of Mr. A. Saxon Snell, F.R.I.B.A., F.R.San.I., and is 30 ft. by 70 ft., and the tank is some feet above the level of the ground.

The students' staircase to the ground floor lands in the entrance hall, from

both sides of which the first and second floor staircase ascends. The staircase throughout is in oak, with a wrought-iron balustrade and bronze wreath enrichments. The head-mistress's room and the porter's room open from the sides of the entrance hall; and the corridors between the science block and the library block, parallel to the front of the building, form one end of the entrance hall.

The corridor is 14 ft. wide, and is paved with black and white and coloured marbles. The walls are oak-panelled, and the ceiling is vaulted.

A glazed screen separates the central hall from the corridor. The central hall is Renaissance in style, and is barrel-vaulted. A gallery runs on two sides and at the north end, and is supported by Ionic columns of oak. A large organ is situated at the south end, the carving of which, together with the screen and desk adjacent, was executed by Messrs. Aumonier.

Other enrichments on the galleries were carved by the same firm. The hall is lit by circular windows on the two sides and large circular-headed windows on each side of the organ at the south end. The roof is supported by steel

PAUL'S HIGH SCHOOL FOR GIRLS, HAMMERSMITH, LONDON: ENTRANCE CORRIDOR. GERALD C. HORSLEY, F.R.I.B.A., ARCHITECT

principals, which are hidden by the vaulting.

The class-rooms open out from each side of the hall, both on ground and first floors, and are separated from the hall by a glazed screen, which is found to be an effective sound-deadener as between the classes. These rooms are ventilated by flues connected to exhaust fans in the roof.

At the east end of the corridor is the science block, comprising a lecture room and physics and chemistry laboratories; at the west end, the library block, with a museum and a school and teachers' libraries.

The remainder of the ground floor between the porter's room and the science block is occupied by music-rooms, which are found to be unsatisfactory, as the sound of the practising interferes with the other classes. These are to be abolished, and a separate music school is to be erected on the west side of the building during the coming year.

The first floor has class-rooms similar to and over the ground floor class-rooms in the main building, and the other parts of the building have no first floor. On the top floor, facing north, is a large room for drawing-classes. The exhaust fans for ventilating the class-rooms are also on this floor.

The exterior is in brick, with stone dressings, and the roofs are covered with green Westmorland slates. In the gables of the science and library wings, their purposes are typified by carved representations of "Science" and "Art" from models by H. Pegram, A.R.A.

The site is about two acres in extent, and there is an extensive playing field at the back of the school.

The general contractors for the whole work were Messrs. Holloway Bros. (London), Ltd.

PICTURE EXHIBITIONS.

The Society of Portrait Painters.

The twenty-second exhibition of this society is open at the Grafton Galleries, and affords a number of opportunities for comparing what may be called the two main but very different objects of portrait-painting—namely, to produce a picture, or to produce a likeness. The latter may be valuable or not, in an artistic sense, according as it is characteristic or not. A mere "good likeness" is interesting only to the friends of the sitter, who want a memorial of what he looked like; what may be called a "characteristic likeness" has a wider interest, though it may not be a pleasing picture; Mr. Maclure Hamilton's "General Booth," in the first room, is an example; there is a little touch of individually observed character about it which gives it more than a personal interest. Mr. Harold Speed's "A profile portrait" is an example of a portrait which is a picture; we are not told, and we do not care, whose portrait it is; it interests us as a picture, for its colour and composition. M. Besnard's large portrait of the French Ambassador to Italy, standing in the centre of a "marble hall," has been characterised in a newspaper as the great work of the exhibition; we should place it as one of the "good likeness" portraits, well painted, but uninteresting in an artistic sense.

Mr. Lavery's "Miss Dundas," in the large room, if it is a good likeness, has both kinds of interest, as it is fine both in colour and line; one of the really good things in the exhibition. Mr. Da Costa's "Mrs. Evans Dick," full-length in front of the dark background of trees, is the old type of Reynolds and Gainsborough composition reproduced in a rather heavy

and loaded style. Mr. Clausen's half-length portrait of a man is a likeness portrait interesting from its broad style and its indication of thought and expression, and Mr. Mouat Loudan's portrait of a lady for its fine colour. Mr. Melton Fisher's portrait of Colonel Ferguson, in the long gallery, is another example in which fine colour gives a special interest to a likeness portrait. Among those in the large gallery which stand out for special interest are two by Mr. J. J. Shannon; one of Mr. Josef Hofmann, on the scheme which was often employed with effect by Franz Hals among the ancients, and Frank Holl among the moderns, in which the face emerges as the high light from out a general darkness, the only other light being the roughly suggested keyboard of the piano. His other picture, "On the Dunes" (which has been exhibited before at the New Gallery), may be a couple of portraits or not, one need not care about that; it is an idyll which one looks at simply as a picture, full of poetic and artistic suggestion—very French in style and feeling, and in the best French style too. It is a work quite above the average range of the exhibition, which contains various good portraits, and a considerable portion that are not so good.

The "private view" scene was rather amusing; the galleries were full of very well-dressed people engaged in conversation, but hardly any one looking at the pictures! Picture exhibitions seem now to be chiefly social functions.

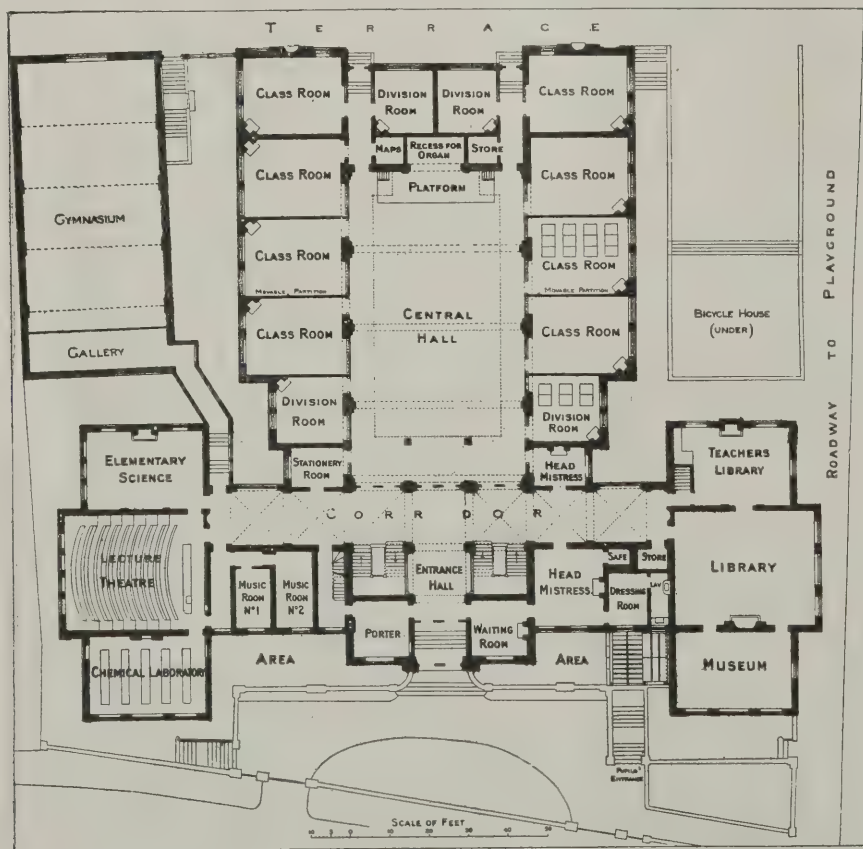

The Goupil Gallery.

At this gallery we find the works of four French painters not much known to fame—MM. Denis, Desvallières, Laprade, and Sérusier, who do not attract us very much. They, of course, all belong more or less to the impressionist school. M. Laprade's two Still Life pictures—"Nature Morte"—are clever examples of brilliant effect produced by strong touches. M. Denis' "La Plage Ensoleillée," nude figures on a beach, with the sea beyond, looks a good effect from the other side of the room; on close inspection the figures are scarcely modelled and the heads like Dutch dolls. Whether that is or is not a good way of producing pictures depends on one's view of the objects of painting. Of the futility of such pictures as M. Desvallières' "La Lecture," we have no doubt; a long bony nude figure, without the slightest beauty of face or form, cleverly painted in a sense, no doubt; but what is the use of painting mere ugliness?

It is a much pleasanter task to contemplate the exhibition of the 137 lithographs of the Senefelder Club, in the upstairs gallery. There is a great deal of capital work in black and white here; among others we particularly admire Herr Gravesande's broad studies of out-door effect, "Hiver en Hollande," "Hambourg," etc.; and, in somewhat the same style, Mr. Barker's "Banking up the Seine"; his "Interior of St. Mark's, Venice," is a subject not suited to black and white. There are some capital sketches by Mr. Pennell, especially "Monceau les Mines"; and there are, in fact, few things in the collection that are not good in one way or another. But then black and white is a good deal easier problem than colour!

The Leicester Galleries.

At this gallery there are two new exhibitions. One of them consists of paintings and drawings by Sir Alfred East mostly small landscape subjects in water

ST. PAUL'S HIGH SCHOOL FOR GIRLS, HAMMERSMITH: GROUND-FLOOR PLAN.

Note: As carried out, the seating of the lecture theatre has been changed so that the light falls from the left.

ST. PAUL'S HIGH SCHOOL FOR GIRLS, HAMMERSMITH: THE GREAT HALL. GERALD C. HORSLEY, F.R.I.B.A., ARCHITECT.

our; of which one of the finest is the other large one of "Morning at St. Ives, Cornwall," an assemblage of fishing-boats in the grey morning light. "On the west coast of Cornwall" is a fine bit of landscape painting, and a large sketch of "Segovia" is an exceedingly effective and picturesque composition. The other room contains a collection of water-colour drawings by Mr. Walter Tyndale, under the title "An Artist in Egypt." They are mostly in a rather sketchy and sketchy style of execution, but Mr. Tyndale represents a good many features of ancient Egyptian architecture very well. In the drawing of "The Hall of Offerings at Deir-el-Bahari" we see, particularly in section, an example of the

ancient method of arch-building with horizontal joints—courses of masonry horizontally bedded, but with their ends cut out to form the appearance of an arch; the drawing forms an exceedingly graphic representation of this curious habit, in Egyptian and in archaic Greek architecture, of building what is an arch in form, but not in structure, the reason for which it is difficult to understand. It may have arisen from the desire to avoid the thrust of the arch, while using the form of it as a matter of appearance. In other drawings, such as "An Arab School at Cairo," we see the early Mohammedan form of stilted four-centred pointed arch, but with the upper portion of the arch forming almost a straight line.

The drawings include a great many architectural subjects, and have special interest from that point of view. The small drawing representing "The Coptic Convent at Assuan," perched in the middle distance of a waste of sand-heaps, is a characteristic bit of Egyptian landscape.

The Fine Art Society.

At this gallery there is a collection of water-colours by Mr. Baghot de la Bere, an artist whose name is unfamiliar to us. A good many of the drawings are practically grotesques illustrating various mediæval superstitions, and more curious than beautiful. Some drawings of dilapidated town architecture—"The New House"; "Laroque"; "Cement Works, Cahors";

etc.—show a good deal of power of producing effect in a broad washy style of execution, quite different from that employed on the grotesque subjects, and more interesting in an artistic sense.

Messrs. Tooth's Gallery.

At Messrs. Arthur Tooth and Sons' Gallery in New Bond Street is a miscellaneous collection of works by deceased British and foreign artists, which contains a number of good things. There are three excellent examples of Prout's subjects of ancient architecture, in which everything seems to be almost in monochrome, except the spots of bright colour supplied by the costumes of the figures; he is an absolute mannerist, of course; one can tell the look of one of his pictures across the room; but then it is a capital manner as far as the architecture is concerned. There are a good figure by Fortuny; a large Scheveningen sketch by Israels; two or three good specimens of William Hunt; a landscape by Copley Fielding, showing very delicate treatment of distance, etc. Some of the names seen here seem to have lost their repute rather. J. Syer was a capital landscape artist of the old water-colour school; two of his works are here, excellent in style of handling, but one never seems to hear of him now; and G. A. Fripp's landscapes, good art of their school, seem somewhat dull in colour to the eyes of the present generation. Two pictures by Kate Greenaway and Mrs. Allingham, exceedingly alike in subject, both representing a rural cottage, a grass foreground, and some small figures, are rather instructive as to the difference between talent and genius. Kate Greenaway's is a good drawing, but Mrs. Allingham's has that something, indefinable, which the other wants. But the collection as a whole is quite an interesting exhibition.

The Alpine Club.

At this room is a collection of pictures by Mr. Roger Fry, as to which it is difficult to make up one's mind whether the artist means them to be taken seriously or not. We have seen very good water-colour drawings by Mr. Fry in former times. Our impression from the present exhibition is that he is playing a cynical joke on the public, and trying to see what they will swallow. At least we regard that as the more charitable conclusion.

STABLE, COWHOUSE, AND PIGGERY FITTINGS.

The architect who is much occupied in designing country-houses often finds that his chief difficulties arise with respect to provision for the housing of the live-stock. Most of the problems with which, in such a case, he is likely to be confronted are anticipated and solved in a neat and handy booklet, entitled "Stable, Cowhouse, and Piggery Fittings," a new edition of which has been produced by the Carron Company, of Carron, Stirlingshire, in which will be found, prefacing an admirable catalogue of fittings, a valuable collection of notes dealing with the questions of site and aspect, dimensions, loose-boxes, coach-houses, washing-boxes, stall-fittings, tiling, manger fittings, stable floors, haylofts, drainage, and other important details; these notes being accompanied by illustrations which include half-a-dozen suggested plans for the arrangement of stable fittings. The list is very comprehensive, comprising every detail about which information is likely to be sought, with, in each instance, price, description, and dimensions.

FIRE PREVENTION NOTES.

Equitable Building Fire.

In the newspaper accounts of the destruction of the Equitable Life Assurance Society's building on Broadway, New York, on January 9th, in which, unfortunately, several lives were lost, it was not always made quite clear that the building was not of modern fire-prevention construction. It was completed as long ago as May, 1870, in accordance with the plans of Messrs. Gilman and Kendall, with Mr. Geo. B. Post as consulting architect, but was completely remodelled, and its height increased by several storeys, in 1887. It then became thirteen storeys high, and is said to be the first office building in which passenger elevators were introduced. Eight of these having been installed, a revolution in the construction of office buildings followed, and the Equitable building was regarded as "the parent of sky-scrapers"; but although for years it was the tallest building in the city, it had long been completely dwarfed by the lofty buildings surrounding it. So old-fashioned had it become that its rebuilding was in contemplation; the acre of ground on which it stood being of far greater value than the structure. As it was a granite building, full of wood-work, its rapid and complete destruction is in no way surprising. Nor should the destruction of any type of skyscraper be

assumed to discredit fireproofing methods and fire-resisting construction. It should be remembered that in a building of such magnitude, holding such a large population, and constantly receiving so many visitors—it is said that 28,000 people passed through the Equitable building in one day—the risks are simply tremendous; and that the great height of the building both encourages the flames and prevents the firemen from getting at them. The chances of ignition being abnormally great and the opportunities of extinction abnormally small, the occasional destruction of a tall building, even of modern construction, should not shake one's faith in the entire efficacy of fireproofing construction when it is employed under fair conditions. It is significant that none of the adjacent more modern skyscrapers, which were so near to the Equitable building as to afford facilities to the firemen for playing on the flames, appears to have suffered.

Fires in Crowded Tenements.

In spite of all that has yet been done to minimise the risk of death from fire, fatalities are still very painfully frequent. They commonly occur in large houses that are let out in tenements to very poor people, who, as a class, are almost incredibly careless with regard to fire risks. Their ignorance and stupidity might possibly

THE EQUITABLE LIFE ASSURANCE BUILDING, NEW YORK, DESTROYED BY FIRE LAST WEEK.

have been greatly mitigated under a more rational system of education; but we have to take the people as we find them: also the buildings in which they are herded, and from which they do not always escape uninjured when fire breaks out. Many of these dwellings have been described as "veritable death-traps," and there is but too little reason to quarrel with the description. Given a building of three or four storeys, the floors of wood of exceeding dryness and inflammability, the only staircase of similar material, the inmates numerous and generally careless, then an outbreak of fire is of strong probability, and when the fire occurs it is sure to be fierce and rapid. In nearly every such instance, the inmates find that escape by the stairs is cut off by smoke or flame, or both, and that the desperate alternative is a leap from a high window. Taking this leap, innumerable people have been killed outright or maimed for life; and such incidents have been so common as apparently to have become accepted as inevitable and almost commonplace. The public apathy in the matter is comparable to the paralysing fatalism which is too lightly assumed to be peculiar to the Eastern races; otherwise the strong case for drastic reform in the regulation of crowded dwellings could not have been so long allowed to pass unheeded.

The Need for Systematic Inspection. No doubt the problem of preventing people from herding together in highly combustible dwellings presents many difficulties; but it is not on that account to be shirked. Two cardinal factors are (1) the objection to an efficient house-to-house inspection in order to ascertain the conditions; and (2) the expense of necessary alterations. The domiciliary visits that are easily tolerated on the Continent would be strongly opposed here, unless it were made perfectly clear that they could not occur generally or arbitrarily, but only in special cases in which there was good ground for supposing inspection to be necessary. Sanitation and water-supply, and, with regard to certain classes of buildings, the means of escape from fire, are even now subject to systematic inspection, and the principle might be easily adapted to such buildings as are known or suspected to be inhabited by numbers of people at serious risk of their lives. It is a well-recognised duty of governing authorities to prevent the spread of disease, and to procure the alterations of any conditions that might give rise to it; and while it may not be possible to contend that fire risks are of comparable magnitude, yet there is here certainly a parity of principle, the only difference residing in the varying degrees of danger. The sole question therefore is whether or not the lives that are lost and the property that is destroyed by fire are worth saving; and it would require considerable courage to answer at least the former question with a direct negative. Yet little or nothing is being done to prevent people herding together in circumstances that tend to favour outbreaks of fire, and to prevent escape from it.

Prevention and Escape. The law as to overcrowding should be made more stringent, and steps should be taken to render administration quite adequate. It is quite possible to prevent too many families crowding together in one house; but that is a question with which we have less to do than with the means that

in any case should certainly be employed to prevent the easy ignition and rapid combustion of large dwellings, and to provide adequate means of escape in case the means of prevention happened to fail. It has sometimes appeared at inquests that huge rents were being drawn from the buildings in which several families were congregated. Nevertheless, it might perhaps be thought on some hands to be not wholly just to compel the wealthy landlords of such property to go to the entire expense of refitting such premises on fire-prevention principles; and, in initiating any scheme for wholesale and complete reform, the local authority might perhaps be reasonably expected to become contributory. Local authorities, however, would probably object to countenancing in any way the overletting of large houses, and all housing reformers would cordially support them in that view. But the fact remains that these dangerously overcrowded dwellings exist in large numbers in various cities, and ought not to be tolerated. They are in various ways inimical to life, and they should be either completely reformed or entirely abolished; either process being conducted in a broadly humane and equitable spirit. It would seem that further legislation on this subject has become necessary; the conditions revealed at the frequent inquests on deaths from fire showing either that existing laws are inadequate or that they are systematically evaded.

The Chesterfield Fatality.

The lamentable occurrence at Chesterfield, by which five children lost their lives, offers but little occasion for comment. At a picture-palace entertainment, about five-and-twenty children, lightly dressed in pantomime style, were assembled in two small upper rooms, awaiting their turn to appear on the stage, when, in some unexplained way, the dress of one of them took fire. There was instant panic, in which five of the children were injured fatally. The published particulars are too meagre to afford any real ground for anything but the broadest generalisations. The first of these to occur to the mind is that the use of common untreated flimsy materials for dressing pantomime fairies, and the like, is unnecessary, and ought to be strictly prohibited. Accidents of the kind have been so numerous as to justify very drastic restrictions as to the character of the fabrics employed in such entertainments; and some revision of the laws and by-laws regulating public entertainments seems to be a matter of considerable urgency. Next (and this remark has no reference to the Chesterfield calamity) it would seem to be desirable to insist on official supervision of places of public assembly, more particularly in those semi-private halls of which the use for such purposes is intermittent and amateurish; as, for example, in many buildings on the outskirts of London where whist-drives, lantern-lectures, concerts, and amateur theatricals are occasionally held. In the dressing-rooms of such places, there is commonly displayed a notice to the effect that smoking is strictly prohibited, but it is always disregarded, as there is usually no one present possessing sufficient authority to enforce it. Anyone who has been behind the scenes at such halls, and observed how recklessly the nervous amateur actors throw down their cigarettes, cigar-ends, and matches, must marvel that fires in such places are not very much more frequent than they are.

BURFORD PRIORY.

Burford Priory, Oxon., which has now been sold by Messrs. Wilson and Gray to Mr. E. J. Horniman, a member of the London County Council, existed in the 13th century as an offshoot of the Abbey of Keynsham. The Harman family converted it into a lay residence, and it eventually passed into the hands of Sir Lawrence Tanfield, who was admitted to the Inner Temple in 1597. While Sir Lawrence lived there he entertained James I., and this was commemorated by a great heraldic panel of the Royal Arms, which is in excellent preservation. The King made his host Chief Baron of the Exchequer in 1607. A later owner was William Lenthal, Speaker of the Long Parliament. After the Restoration Charles II. dined at the Priory, and William III. was also a visitor there. Old pictures of the priory show that one wing had fallen into decay, although remains of it are still to be seen.

The most interesting parts of the interior include Lenthal's chimneypiece in the drawing-room, the ceiling dating from the time of Henry VIII., which has been well restored, the staircase, the Gothic arcading of the hall, the great fireplace, and the ceiling of the inner hall. The old chapel, which has not been touched, is connected with the house by cloisters and an upper gallery opening from the drawing-room. In the gardens, bounded by the River Windrush, there are many interesting features. Close to the house is a typical piece of Jacobean garden architecture, one of two summer houses on the west wall.

The Home Farm comprises Kitt's Quarries, from which came much of the stone for the interior of St. Paul's and Westminster Abbey, and a pretty old house which had been a residence of Waller.

DETAILS, OLD & NEW.—XXXVI.

Bridge at Newbury.

Newbury, in Berkshire, possesses many interesting examples of eighteenth-century building—chiefly house fronts, which line the long main street and give it a quiet and comely air. Modern commerce is unhappily making sad inroads in the old red-brick fronts, substituting areas of plate glass for the proportionate windows of the olden time. A small river, the Kennet, flowing with a quiet and sluggish movement, bisects the town. And the delightful bridge, the subject of our illustration, was thrown across it in the eighteenth or early nineteenth century. It is built with one arch laid to a happy curve, which, springing from the walls of the houses on either side (which rise out of the water), reminds one of Holland. The arch is built of stone, the voussoirs long and short, with brick infilling to the spandrels. At the road level a stone cornice is built to a slight curve. And above that a stone blocking-course with a balustrade. Curiously enough, the balusters are of cast iron, although the pedestals and the capping moulding are stone. Why this was done it would be difficult to say; for they must have cost a great deal more to cast than to turn out of stone. The half-balusters butting against the pedestals are also iron. There are many small bridges up and down England, but none more charming than this one at Newbury, with its repose and quiet dignity. It also meets utilitarian needs by being nearly level.

FIRE PROTECTION IN PARIS.*

With respect to fire-protection, as with regard to most other subjects, the various countries have much to learn from each other. In recognition of this fact, the British Fire Prevention Committee has, at different times, sent special commissions to study the methods and organisation of Austria, Hungary, and South Germany; Italy, Switzerland, and Alsace; Northern Germany; and, in August, 1911, Paris. A report upon this last-named visit has been prepared by Mr. Edwin O. Sachs and Mr. Ellis Marsland, and published as a special issue of the "Journal" of the committee. The special commission included, besides the two gentlemen named, the Earl of Londesborough, Mr. Horace S. Folker, and others.

The visit was timed to coincide with the review and competitions held in support of the firemen's widows and orphans' fund, which events brought to Paris a large number of provincial firemen, whose equipment and methods could therefore be the more easily observed and compared. The annual meeting of the International Fire Service Council was arranged to take place at the same time; and altogether the Commissioners were very fortunate in the enjoyment of opportunities of which they seem to have taken full advantage.

Great attention is paid to the means of securing physical fitness and perfect discipline in the members of the Paris Fire Brigade. Daily gymnastic exercises are conducted at all barracks, the practice including Swedish muscular work, and consequently the commissioners are able to report that "the strength, celerity, and stamina of the Paris firemen, owing to systematic athletic training, is probably unsurpassed," while there is an entire absence of corpulence. The brigade of 1,800 has an extraordinary number of superior officers—48, as compared with Berlin's 26 officers to 1,040 men, Vienna's 9 officers to 550 men, Hamburg's 12 officers to 512 men, and London's 5 officers to about 1,400 men. In the case of London, however, there are civil engineers, surveyors, inspectors, and others, who are left out of the count in its computation.

Approval is expressed of the centralising of the brigade's organisation work at headquarters other than a fire station; the advantages of freeing the organisers from the turmoil and interruptions of "turning out" being clearly obvious, while any disadvantages that might be supposed to arise from this detachment are counteracted by central position, and the fullest possible provision of modern means of instant communication. Some of the fire stations are of old building, and therefore do not fully conform to modern requirements; but newer stations are not only well equipped, but possess architectural merit. The Paris Fire Brigade was, in 1899, the first in Europe to adopt motor traction. The appliances are driven by petrol motors of uniform pattern; and the commissioners very justly comment upon the danger of thus depending on one system. In time of war or tumult, the

* Record of the Special Commission formed by the British Fire Prevention Committee to Visit Paris, August 1911, being a Diary and Notes compiled by Edwin O. Sachs, F.R.S.E., and Ellis Marsland, District Surveyor, from Memoranda prepared by the members of the Commission and from data put at the Commission's disposal by the Paris Fire Authorities. One hundred and thirty illustrations. London: Office of the British Fire Prevention Committee, 8, Waterloo Place, Pall Mall. Price 7s. 6d.

supply of petrol might be cut off, and the brigade rendered powerless at the very moment when its services were most needed. The salvage corps is not, as with us, an independent organisation, but is an arm of the brigade, 75 per cent. of the firemen being specially trained in the work; but the insurance companies subscribe £8,000 a year towards the expenses of this service. The commissioners have an interesting note on the dangerous-structure gear with which the Paris brigade is equipped; this consisting chiefly of the means of rapid shoring and strutting of tottering walls, and gear for holding up walls and ceilings. It is further suggestively noted that here, as in Berlin, facilities are afforded for the training of cadets in fire practice, as well as for the systematic drilling of squads of men from the army and navy. The brigade itself is described as "a military regiment of infantry, directly responsible to the usual military chiefs and the Minister of War of France, the regiment being placed at the disposal of the community of the City of Paris to the orders of the Paris Prefect of Police, and the cost of its maintenance, housing, and equipment being borne by the municipality, who, in their turn, receive certain contributions towards the expenditure, such, for instance, as the contributions of the insurance companies towards the salvage section." The organisation is described with admirably succinct completeness in the introduction to the report under notice. So also are the means of fire prevention in Paris, which, it seems, are, on the whole, as sadly to seek there as they are in London; the commissioners putting the case very politely when they say that "Fire prevention in a general sense has not yet been extensively developed in France, nor has it as yet become a popular or much considered subject either among engineers, architects, surveyors, or the officers of the provincial fire service."

The tube railways, however, seem to have been very carefully constructed with a view to fire prevention, the stations being large, the steps having an easy gradient, the subways being simply rather than tortuously planned, and the arrangements for cutting off the high-tension current in case of accident being specially happy. Neither the large shops nor the theatres appear to offer us any models for imitation; in fact, it would almost seem that in these respects Paris has a good deal to learn from London.

The report contains a fully illustrated account of the Paris Fire Brigade—its history, its constitution, its organisation, equipment, and housing. The headquarters, which, as before remarked, are not a fire station, but a central office, where nearly all the secretarial work is done, and where the colonel commanding and most of his staff reside, are next door to the police headquarters, as nearly as possible in the centre of the city. The Montmartre station is of modern construction, and contains quarters for three officers and 131 men. The Rue Blanche station, which is of older type, houses three officers and 124 men. The Port Royal station, for three officers and 130 men, is still older. Chaligny has three officers and 129 men. These are all "barrack" stations. That of Chateau d'Eau is a *poste*; the distinction between the *poste* and the barrack stations being that while the former are supplied by "shifts" of men from outside, and provide sleeping accommodation for only a few, the former house an entire staff.

LONDON'S MAIN DRAINAGE
PUMPING PLANT.

A notable addition to the pumping power at the London County Council main drainage station, Crossness, is about to be made. This station receives the total discharge of sewage from the whole of the south side of London. The sewage reaches the station in three outfall sewers each 11 ft. 6 in. in diameter, and the greater proportion of the flow is pumped into precipitation channels. The pumping plant, as originally installed in 1865, consisted of four beam engines working reciprocating ram pumps, each capable of dealing with 125 tons a minute. These engines were converted into triple-expansion sets in 1901, and in 1899 an addition was made to the plant of two triple-expansion vertical engines, each actuating three ram pumps and delivering 140 tons a minute. The total pumping capacity of the station at present is therefore 780 tons a minute. Steam at a pressure of 150 lb. is supplied by ten 30 ft. by 8 ft. Lancashire boilers, of which five are under steam at one time.

The recent addition of another low-level outfall sewer has made it necessary to supplement the pumping machinery, and it has been decided to do this by the provision of centrifugal pumping plant which will combine efficiency with large discharging capacity and will be immediately available at periods of heavy rainfall, when the quantity of sewage and storm water arriving at Crossness is doubled or trebled in a short space of time.

A tender from Messrs. Dick, Kerr, and Co., Ltd., has been accepted for the construction of an engine-house which will be capable of housing eight sets of centrifugal pumps and engines, each unit to pump about 100 tons a minute. This engine-house, with its suction culverts and connections, will be situated on the eastern side of the existing main engine-house, and the foundations and suction culvert will be carried down to such a depth that it will be possible to empty, if necessary, the suction culverts feeding the pumps in the existing engine-house. The steam for the engines will be obtained by adding to the present boiler installation four boilers similar to those now in use, so that the new installation will work as an addition to and in conjunction with the present pumping plant. Four sets of engines and pumps only will be erected at first, and tenders for their manufacture are under consideration.

The work will extend over a period of two years. The whole of the works are being carried out to the design of Mr. Maurice Fitzmaurice, C.M.G., the engineer-in-chief to the London County Council, and Mr. H. M. Rounthwaite, the mechanical engineer, will be responsible under the engineer-in-chief for the machinery.

Proposed Bacon Factory at Bulawayo,
Rhodesia.

A bacon factory of considerable dimensions, and with a capacity of 500 pigs per week, will be constructed at Bulawayo, Rhodesia, during the present year by the British South Africa Company. Specifications and plans are being prepared by Mr. Loudon M. Douglas, F.R.S.E., technical adviser to the British South Africa Company, 2, London Wall Buildings, London, E.C., from whom all further particulars may be obtained.

PORTLAND CEMENT ON PUBLIC WORKS.

By GERALD THORNHILL, Assoc.M.Inst.C.E.

(Concluded from page 54, No. 886.)

Hardening.

A test of the initial hardening of Portland cement is urgently needed, and would be very useful for the following reasons: (1) It would take the place of the Final Set test. (2) It would reject defective cement which hardens only on the surfaces. (3) It would give a better idea of the comparative strength of the sample than the tensile test does. (4) It would enable a user to differentiate between quick and slow hardening cements; and (5) It could be standardised. Reasons (1), (2), and (3) have already been referred to.

Coming to the fourth reason, it may perhaps be as well to state first that setting and hardening are not synonymous terms. The two properties are totally different, and seem, in point of time at any rate, to have no connection with each other. There is, however, a sort of general law, which has been established by numerous experiments, that, given two samples of the same make of cement, one quick setting and the other slow setting, the quick setting is the slower hardening. Possibly an extreme instance of this was obtained by testing two samples of one maker's cement. The initial sets of these two samples were as far apart as 16 minutes and 8 hours, but at the end of 24 hours the slow-setting sample was many times harder than the quick setting. Table 3 gives other instances of this strange law.

Again, there is an extraordinary difference in the rate of initial hardening of various makes of cements, and the difference is perhaps even more noticeable in various blends of rotary and chamber kiln cement from the same works. Thus, two samples obtained from one manufacturer, and having the same initial set, were tested for hardness, at 24 hours old. Sample "A" required a pressure of 175 lb. for a penetration of 19 millimetres. Sample "B" only required a pressure of 36 lb. for the same penetration.

FIG. 2.—EXPERIMENTS MADE TO ASCERTAIN RELATION BETWEEN HARDENING OF NEAT CEMENT AND THE SAND TENSILE AND COMPRESSION TESTS.

Age.	Hardening.		Tensile.		Compression.	
	Lbs. pressure divided by millimetres penetration.		Lbs. per square inch.		Tons. per square foot.	
	Sample A	Sample B	Sample A	Sample B	Sample A	Sample B
24 hours ..	7.9	3.6	99	39	50.2	18.3
48 hours ..	14.7	10.5	261	185	103.5	65.6
3 1/2 days ..	29	22	239	170	141.5	97.6
7 days ..	46	50	337	311	153.4	174.7

FIG. 3.—EXPERIMENTS CONDUCTED BY A CEMENT MANUFACTURER TO ASCERTAIN THE HARDENING OF HIS OWN CEMENT.

			Resistance for 19 millimetres penetration.		
			24 hours old.	48 hours old.	72 hours old.
Sample No. 1.	Initial Set	2 min.	Lbs.	Lbs.	Lbs.
..	25	—	200
" " 2.	" 4 "	..	75	225	—
" " 3.	" 41 "	..	175	300	—
" " 4.	" 87 "	..	200	350	—

The figures show that the slower the initial set is, the harder is the cement in its early ages.

Can it be seriously contended that these two samples are equally suitable for certain classes of work? "A" made a fairly hard concrete in normal time, whereas the concrete made with "B" was so soft that, at 5 days old, stones could be picked out of it with the fingers. Both samples passed the British Standard Specification, and the same aggregate was used for the concrete in each case.

For structural concrete work over centres, between shutters, and in deep heavy trenches, a quick-hardening cement is essential. In placing a contract for such work, the usual practice hitherto has been to order a quick-setting cement, under the impression that this would ensure quick hardening. But this has been proved above to be quite an erroneous idea, although some quick-setting cements may give good hardening results.

It is impossible to know whether a cement hardens quickly or slowly, unless it undergoes a hardening test.

Passing to the fifth reason, when the size of the initial set pat has been fixed, that set will be standardised. The pat used in ascertaining the initial set can also be used for the hardening test.

Aeration.

The question whether cement should or should not be aerated is always a bone of contention on big public works. Up to quite recently, most engineers specified that all their cement should be aerated. In fact aeration was looked upon as the panacea for all the ills and weaknesses that cement is subject to, and this deservedly so, for there is hardly a fault or defect that is not curable by aeration for a longer or shorter period.

Apart, however, from any advantage gained in the quality of a cement by aeration, comes the question, Is it economical? It is, of course, a well-established fact that aeration increases the bulk of dry cement; but what may not be so well known is, that cement also increases in

weight during aeration, through absorption of moisture from the atmosphere. Further, aerated cement requires more water to combine properly than non-aerated. Experiments have been carried out to ascertain the degree of increase in weight and bulk, and the particulars show that, due to aeration only, the increase in weight is 3 per cent., in bulk 11 per cent., and in bulk of neat cement mortar 8 1/2 per cent.

By the courtesy of Mr. G. N. Yourdi, M.Inst.C.E., the author is enabled to state in relation to the aerating shed of the Birmingham Corporation, in the Elan Valley, that there were booked out of the shed about 2,000 tons more than were received into it; therefore, on paper, the gain in passage through the shed was, say, 2,000 tons, or 1 1/4 per cent. This apparent gain may or may not have been wholly due to aeration. The bags sent out of the shed were supposed to be full weight, and liable to be checked at any time by one of the engineers. Then, again, considerable waste often occurs in an aerating shed, due to the flour being carried away by the draughts, or on men's clothes and railway wagons.

Take the figures given by the experiments and assume that 10,000 tons are wanted by a contractor, and, further, that the cement has to be measured, when making concrete, by volume.

FIG. 4.—EXPERIMENTS MADE TO SHOW THE EFFECT OF AERATION OF THE STRENGTH OF CEMENT AT DIFFERENT AGES.

No. 1.—EFFECT ON THE STRENGTH AT 7 DAYS OLD.

Description.	Sand Tensile lbs. per sq. in.	Sand Compression tons per sq. ft.
Aerated for 13 days ..	179	116
Non-aerated ..	249	173

No. 2.—NEAT TENSILE TEST UP TO FIVE YEARS.

Description.	7 days.	28 days.	3 mths.	6 mths.	1 year.	2 years.	3 years.	4 years.	5 years.
Aerated for 9 months ..	590	720	765	685	711	1035	890	705	800
Non-aerated ..	1454	1165	—	—	778	827	909	734	652

Aeration would increase his 10,000 tons to 10,300, and would make this 10,300 tons, owing to the increase in bulk of 11 per cent., go as far as 11,400 tons of non-aerated cement. So that aeration saves him the cost of 1,400 tons at, say, 30s., or £2,100. The cost of aeration at 9d. per ton would be £375, so that the saving would be £1,725.

Even if the cement is measured by weight, aeration would show a profit of £75, for the increase in weight would bring in £450, against the cost of £375. And in this case much better work would result, because there would be a large increase in the volume of the cement used and in the mortar produced. This is true, because, although aerated cement is not as strong in its initial stages as non-aerated, it gains rapidly in strength, and sooner or later becomes quite as strong as the other. See Table 4.

Measurement of Cement when making Concrete.

The author cannot too strongly deprecate the existing practice of measuring cement by volume instead of by weight. It affords an astute contractor a splendid opportunity of making a handsome and perfectly legitimate profit at the expense of the quality of the work.

FIG. 5.—EXPERIMENT MADE TO ASCERTAIN HOW MUCH THE WEIGHT OF CEMENT REQUIRED TO FILL A BOX WAS AFFECTED BY DIFFERENT METHODS OF PUTTING THE CEMENT INTO THE BOX.

Description.	Weight of box and cement.		
	Cwt.	qrs.	lbs.
(1) Box filled straight from bags—			
1st time	3	3	20
2nd "	3	3	27
3rd "	4	0	3
Average	3	3	26
(2) Box filled with shovel—			
1st time	3	2	23
2nd "	3	2	24
3rd "	3	3	2
Average	3	2	26

N.B.—28 lb. less cement contained in box when filled with shovel.

The usual practice in this country is to specify, in regard to concrete, that it shall consist of certain proportions of cement, sand, and broken stone, and that proper gauge boxes for measuring these proportions are to be furnished; in other words, the cement is to be measured by volume.

Such a clause is a source of joy to an experienced contractor, because he knows that, by careful management, he can make 90 to 95 tons go as far as the 100 tons of an inexperienced man.

In carrying out the work he will have one man, whose sole duty it will be to fill the cement measure carefully, lightly and gently, a shovelful at a time, instead of filling it in the usual "administration" way by dumping the bags straight into the box.

An experiment was conducted in order to ascertain how much the different ways of filling affected the weight. The particulars of this experiment are given in Table 5, and the result shows the difference in weight to be 6.8 per cent., the measure filled with a shovel being the lighter. Now assume that a contractor has a concrete mixer which turns out 160 mixings of one cubic yard each per day. On every mixing he saves 28 lb. cement, and on the day's work 2 tons; so that his saving every day, with cement at 30s. per ton, is £3. On every 50,000 cubic yards of 6 to 1 concrete he saves 680 tons of cement, or £1,020. This saving is of course effected at the expense of the quality of the work. In the face of these figures it is difficult to see any reason for continuing the present practice of measuring cement by volume, especially when it is so much easier and simpler to measure by weight. The manufacturer weighs the cement and is prepared to guarantee that each bag weighs so many pounds, therefore each bag contains a known quantity and does not need to be reweighed. If engineers would specify that concrete shall consist of certain proportions of cement, sand, and stone, the cement to be measured by weight and gauged with the sand and stone on the basis that one cubic foot of cement weighs 90 lb., the contractor could easily make his ballast box or hopper to suit either one or two bags of cement, and no measurement or weighing would be necessary.

In conclusion, the author tendered his thanks to Mr. Edward Sandeman, Inst.C.E., President of the Institution

of Water Engineers, for the invitation to read this paper and for permission to make use of the results of experiments conducted by his cement tester, Mr. T. Smith, to whom the author is also indebted.

RURAL HOUSING AT BYFLEET.

An interesting experiment that has been carried out at Byfleet, in the heart of Surrey, deserves far more attention than it has received. Byfleet is a wealthy residential district about an hour's journey from Waterloo. There has long been a dearth of cottage accommodation, and some of the men in the employ of landowners have been compelled to travel as much as 20 miles in a day in order to get to and from their work. Recently a few of the residents started a scheme known as the Byfleet Tenants, Ltd., and have carried it out under the auspices of the Housing of the Working Classes Act of 1890, and the Housing and Town Planning Act of 1909.

They intended to build 85 cottages, at a cost of about £30,000, and the scheme has developed down to the present to the extent of 30 cottages, 14 single-roomed flats with bed alcoves, and 18 flats with three rooms. These 62 homes, which have been created at a cost of £15,000, on land costing £600

per acre, are let at low rents, which, however, return four per cent. Houses and flats here have been designed by Mr. Raymond Unwin, and they make up a charming little street in close proximity to the station and surrounded by a little wood of birch trees. All the white-fronted and red-tiled dwellings are very substantially built. Each single-room flat has a bed alcove with a window to it, a kitchen with constant hot-water supply, electric light, of which the cost is included in the rent, and a small garden. The first-floor flats have a balcony. Larger flats have a sitting room, two bedrooms, bath, scullery, and pantry, electric light, and garden.

The rent of single-room flats, including all rates and taxes, is, 4s. 9d. per week, and for the larger flats the price is 6s. 3d. The cottages have three bedrooms, bath, either one or two living rooms, and garden, and the rent varies from 7s. 6d. to 9s. 6d. per week. There are no restrictions, but workers have the preference over all others, and both houses and flats are being snapped up as quickly as they can be built. Yet with land at the high price that prevails in Mid-Surrey, with thoroughly sound building and expensive modern drainage system, and every convenience for the tenants that skill and knowledge can devise, the scheme yields four per cent.

This pulpit, erected to the memory of Mrs. C. N. Peal by her sons, is executed in Caen stone with alabaster capping. The whole of the work was carried out by Mr. Gilbert Seale, sculptor.

PULPIT IN ST. JOHN'S CHURCH, EALING, LONDON.
HALL-JONES AND CUMMINGS, ARCHITECTS.

A JAIL ON THE RADIAL SYSTEM.

The new jail at Nairobi, East Africa, on the flats to the east of the town, presents many features that are of much novelty of interest for the European. The warders' huts, agreeably to a native's idea of comfort, are of mud and wattle, with grass thatch roof. Of 14 ft. diameter, with doorway and a small window opening at the opposite side, they are airy when open, and cosy when shut at night. Fifty-six such huts, laid out in two lines forming a square, leave an open space for drilling in the centre. These warders' huts are placed to the eastward of the jail building.

The original intention was to have a jail square of outside solid stone walls. From a central octagonal space, eight radial lines of cells were to run to each corner, and to the middle line of each side. On this central space a look-out tower was to be built. Between the radial lines of cells were to be open courtyards bath-shed, work-shed, etc.

This plan of jail building has been followed in India in some of the larger places of detention, and, provided there is plenty of land that is not too expensive, provides a system whereby an absolute close watch—from the central octagon—can be kept on all the cells.

The completed jail was originally estimated to cost about £20,000.

Later a revised plan was produced. It appears that the radial system of cells was objected to by the medical authorities as not providing sufficient ventilation in the ends abutting on the solid stone outside walls. Work in the meantime had been commenced on the building, after the radial system, and this portion has been completed. Future extensions will probably take the form of lines of cells abutting on to a central extended space—that is, cell lines from the side to the centre, running parallel with each other. This will facilitate the passage of air, thus guaranteeing that absolute ventilation so much desired by medical authorities.

The finished portion of the structure represents three of these radial lines of cells—or, to be exact, two and a half radial lines, surrounded by one side and a half of exterior wall. This outside wall is of solid stone, 2 ft. thick by about 15 ft. high, with coping stone on top suitable for a warder on watch pacing his rounds. The outside walls of the cells, lining the court-yards, are of solid stone, while inside walls are of cement blocks about 10 in. thick. One radial line consists of four large rooms, each of about 50 ft. by 20 ft., two of these being on each side of the corridor. There are six barred windows in each room of about three and a half feet. These, taken in conjunction with two doors in each room, provide plenty of air and ventilation. Besides these there are a number of ventilating spaces below the roof of the corridor, which is raised about a foot above the cell's roof. The roofs are of solid reinforced concrete, durable, strong, clean, and watertight. Floors are of cement, dry, clean, and healthy. In these community cells, each supposed to give sleeping accommodation to thirty-three prisoners, the prisoners sleep on thick coir mats spread on the floor, curled up in large thick woollen blankets. Emergency earth closets, abutting on and connected with these community cells for use at night time, have been constructed. All the earth closets in the place are entirely built of stone and cement.

The second radial line of cells is for those condemned to solitary confinement. There is a total of twenty-two cells, eleven on each side. Each of these is furnished with a large barred opening high up on the wall. The door of every cell has also a small barred opening, serving for ventilation, but primarily for the warder's eye. Ten cells, five on each side of the corridor, at the further end of this second radial line, are for native women prisoners. A gate across the corridor isolates these, and at the end of the radial line, which runs towards the corner of the outside walls, is the court-yard for the women's use. This courtyard is supplied with bath-room and two earth closets.

Then the third radial line, or, rather, half a line, as there are only the corridor and cells on one side, is for European prisoners. It consists of eleven cells, in all respects like the other solitary cells, with an additional opening at the outside end of the corridor through the main wall for the separate ingress and egress of white prisoners. In the courtyard in connection with this line of cells is a kitchen, and in the building a dining-room, two bath-rooms, and two earth closets are supplied. In the finished scheme, the European quarters will, it is understood, be removed to a separate building.

The interior ends of these radials are abutting on the central space, where there is a kitchen for the cooking of the convicts' food.

On the outside yard to the eastward is an open work-shed, and also a large bathing-shed. The east side of the prison and the south side are at present fenced with wire and interlaced split-bamboos.

The main entrance is to the north side, and is of temporary construction, built of cement blocks. The offices are of corrugated iron, and are placed inside of the temporary gateway. To the right of these, on entering, lies the hospital, temporarily built of cement blocks. There are two rooms for patients, with the usual hospital accompaniments of dispensary, kitchen, etc. On the left is the gallows-room, with drop pit and two cells, for prisoners under sentence of capital punishment. These cells are constructed of cement blocks, iron roof, and wooden ceiling.

An abundance of water is supplied by a pipe leading from the town main to the inside of the prison walls. All rain and other water is to be let off by cement drains.

Something less than £10,000 had been expended on the portion of the Nairobi jail so far completed.

A curious complication of the architect's functions may be noticed. It seems that he was expected to provide a fortress as well as a jail! Commenting on the calculation that the housing of the prisoners will cost about £3 per head per annum, the "East African Standard" remarks that "such expenditure could only be justifiable were the building meant for other and more profitable uses. If, for instance, it were intended as a place of defence in the event of any general native revolt, and could be thus used as a refuge for the wives and children of Europeans and Indians, the interest on the capital expenditure would be a well-paid insurance. So far as we have been able to ascertain, no such idea has been in the minds of the authorities responsible for this expensive structure. Nor is the building suitable, nor likely to be suitable, for defence purposes. Its location in the open plain is desirable, but there it ends. There are no loopholes,

and no corner turrets for a side-raking fire from machine guns. The water supply, conveyed to the interior of the walls by a single pipe, is liable to be cut off; and, finally, the fact that the outside walls are incomplete makes the jail for the present absolutely inadequate for any purposes of defence or refuge."

STANDARDISING HOT-WATER SUPPLY FITTINGS.

Mr. Henry Lea, M.Inst.C.E., writing in the "Times" engineering supplement, states that for some time past there has been a difficulty, increasing from year to year, in relation to the behaviour of iron and steel pipes, cisterns, cylinders, and boilers used in the supply of hot water for baths, lavatories, etc., in private houses, hospitals, and other institutions where the public supply of water has been of a very soft quality. Even galvanised iron succumbs, and in the case of steel galvanising affords but very slight protection from the corrosion which takes place, in many cases with such rapidity as to become a serious and costly matter.

Thanks to the efforts of the British Engineering Standards Committee, iron and steel pipes and the screw threads for them have been standardised for some years past, as set forth in Report No. 21, and great benefit has been felt from such standardisation. In the case of copper pipes, which do not require for the purposes under consideration to be nearly so thick as iron and steel pipes, the screw threads which are suitable for the latter are impossible for the former, because from the pitch and depth of such threads the thin copper pipes would be nearly cut through by the thread. The first thing, therefore, to be done is to standardise the copper tubes and their screw threads, for this is the foundation for nearly all that will have to follow, and this subject is now engaging the attention of a Standards Sub-Committee, whose work will be largely assisted by the information which is being collected and carefully tabulated by Associations of those concerned in the business. The National Association of Water Heating and Domestic Engineers, numbering some 70 firms of contractors, the Institute of Heating Engineers, consisting of manufacturers and professional men, and the Institution of Municipal Engineers are taking a keen and active interest in this work, and it is hoped that at an early date the Standards Committee, furnished with all the necessary details, will be able to issue their Report upon Standard Copper Tubes.

Upon this report as a foundation the next step will be to take up the subject of union joints, then, probably, hot-water cylinders, and, finally, it is hoped, fittings generally, as, for instance, gunmetal bends, tee-pieces, and valves. The standardisation of these things will be invaluable. Such is the state of confusion which now exists that the labour and cost of keeping a complete stock are becoming unbearably excessive. One London firm has stated that were a reasonable and common-sense system of standardisation insisted upon the result would be a saving of about £700 a year in its cost of stock keeping.

It is highly satisfactory (Mr. Lea concludes) to find manufacturers, contractors, and municipal authorities combining together to bring about such an important reform as this will undoubtedly be if carried out to a full conclusion.

COMPETITIONS.

Workmen's Dwellings, Banbury.

The Council of the R.I.B.A. are of opinion that the conditions of this competition are very unsatisfactory, but in view of the lateness of the date they do not see their way to inform members that they must not take part in it. They express the hope, however, that members will refrain from doing so.

Burgh School, Greenock.

A note from the R.I.B.A. states that: "Members and licentiates of the Royal Institute must not take part in this competition."

Extension to Salford Union Offices.

Fourteen designs were submitted in this competition, which is for extensions estimated to cost from £4,000 to £5,000, and Mr. Paul Ogden, A.R.I.B.A., the assessor, has made the following awards: 1st (£20), Messrs. Topham and Adshead, Manchester; 2nd, (£10), Mr. J. Bushell, Manchester.

Baptist Church and Schools, Nottingham.

Mr. Herbert W. Wills, A.R.I.B.A., the assessor in this competition, for work which is to cost about £7,000, has selected the designs submitted by Messrs. Ernest R. Sutton and F. W. C. Gregory, of Nottingham.

Scottish Memorial to King Edward.

A conference of Scottish local authorities, convened by the Glasgow Corporation, was held in Glasgow last week to consider the proposed memorial to King Edward. The meeting decided that the memorial fund should be applied in the first place to the establishment and maintenance of an institute to be called the King Edward Memorial Institute of Preventive Medicine; the institute to be dedicated primarily to research in relation to tuberculosis, and to be available to the whole of Scotland. A committee was also appointed to consider the question of the erection and maintenance of convalescent sanatoria.

LIST OF COMPETITIONS OPEN.

JANUARY 20TH, 1912. STATUE AT HAVANA.—Competition instituted by the Cuban Government for the erection at Havana of an equestrian statue of the Cuban General Maceo. Plaster models competing to the "Comisión Ejecutiva, Monumento al General Antonio Maceo, Secretaria (de Instrucción) Pública y Bellas Artes," Havana, before January 20th. The sum of 100,000 pesos (about £20,600) has been voted for the work. British sculptors proposing to compete could first put themselves into communication with the Commercial Intelligence Branch of the Board of Trade, 1, Basinghall Street, E.C., where also other particulars (in Spanish) may be obtained.

JANUARY 29TH. NEW GOVERNMENT PALACE, MONTEVIDEO.—Designs are invited for a Government Palace and a town improvement scheme. Premiums: For the former, £2,125 and £850; for the latter, £1,060, £640, and £425. Conditions, etc., at the Board of Trade, 73, Basinghall Street, E.C.

JANUARY 31ST. THE FEDERAL CAPITAL CITY, AUSTRALIA.—Competitive designs are invited by the Commonwealth of Australia for the laying-out of the Federal Capital City. Premiums are offered as follows: 1st, £1,750; 2nd, £750; 3rd, £500. Conditions, together with particulars, plans, and instructions, may be obtained at the office of the High Commissioner for Australia, London. Designs must be delivered by January 31st, 1912, to King O'Malley, Minister of State for Home Affairs, Commonwealth of Australia.

[The Institute of Architects of New South Wales and the R.I.B.A. have asked members and Licentiates not to take part in this competition unless the conditions are made more satisfactory. See our issue for November 8th, p. 485, and article printed in the issue of November 22nd, p. 537.]

FEBRUARY 3RD. NURSES' HOME, BOLTON INFIRMARY.—Premiums, £30, £20, and £10. Mr. John B. Gass, F.R.I.B.A., has been appointed the assessor.

FEBRUARY 15TH. NEW PARLIAMENT BUILDINGS, WINNIPEG.—Regulations governing the competition for the new Parliament buildings for the City of Winnipeg may be had from the High Commissioner for Canada, 17, Victoria Street, Westminster.

FEBRUARY 17TH. NEW OFFICES FOR THE PORT OF LONDON.—The Port of London Authority invite preliminary sketch designs for new head offices in Trinity Square, and for lay-out of a building site. Sir Aston Webb, R.A., is the assessor.

FEBRUARY 17TH. ELEMENTARY SCHOOL, YORK.—The City of York Education Committee invite competitive designs for a public elementary school to be built in Campheshon Lane, Bishopthorpe Road. Assessors, Messrs. T. Mellard Reade and Son, Liverpool. Apply, J. H. Mason, secretary, Education Offices, Clifford Street, York.

MARCH 15TH. LAYING OUT ESTATE, PRESTATYN.—Designs for laying-out the Prestatyn Estate are invited. Premiums of £50, £30, and £20. Application (with 19s. 6d. deposit, returnable) was to be sent by January 8th to Lord Aberconway and the Trustees of the Prestatyn Estate, 33, Henrietta Street, Strand, W.C. Designs by March 15th. Judge, Mr. H. V. Lancaster, F.R.I.B.A.

MARCH 16TH. PUBLIC OFFICES, HARROW.—Harrow-on-the-Hill Urban District Council invite designs for enlargement and alterations of their public offices, at a cost not to exceed £4,500. Premiums, thirty, twenty, and fifteen guineas. Plan and instructions (£1, returnable) from Mr. J. Percy Bennetts, Engineer and Surveyor to the Council, Council Offices, Harrow-on-the-Hill. R.I.B.A. will be asked to appoint an assessor.

JUNE 28TH. TOWN PLANNING SCHEME, HALE, CHESHIRE.—Schemes are invited by Hale U.D.C., for town-planning in this district, for which premiums of £50 and £25 are offered. Apply to Council Offices, Hale, Cheshire.

JULY 1ST. NEW CITY EXTENSION SCHEME, DUSSELDORF.—Premiums £1,000 and £375. Particulars from the Chief Burgomaster, Dusseldorf.

AUGUST 30TH. THE HENRY SAXON SNELL ESSAY.—The Henry Saxon Snell prize of fifty guineas and silver medal of the Royal Sanitary Institute is offered for an essay on "Suggestions for Improvements

in the Ventilating, Lighting, Heating, and Water Supply Appliances and Fittings for an Operating Room and its accessory rooms for a General Hospital of 400 Beds (no Students)." Essays (in which two competitors of different professions or crafts may join) to be delivered before 4 p.m. August 30th, to the Secretary, Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., from whom full particulars may be obtained.

NO DATE. HOUSING SCHEME, SADDLEWORTH.—The council invite architects to submit designs for houses suitable for the working classes, to be built of stone and in blocks of not more than six, on certain plots of land which have been selected in the district of Saddleworth. The Council will make the following awards: For the first selected designs £25, second £10, third £5. Descriptions of the houses and other information may be obtained on application to E. Rowbotham, Clerk to the Saddleworth Urban District Council, Uppermill, near Oldham.

THE LATE MR. JOHN
TOMLISON.

A PIONEER OF NATIONAL FEDERATION.

With the greatest regret we announce the death of Mr. John Tomlison, secretary of the Manchester, Salford, and District Building Trades Employers' Association, and of the Preston Building Trades Employers' Association, and formerly secretary of the Lancashire, Cheshire, and North Wales Federation. Mr. Tomlison, who died at his residence, "Norton Lees," Ansdell Road, Lytham, on Saturday, January 6th, after a long and painful illness, was born at Preston on August 10th, 1856. At the age of 15, he entered the office of his father, with the intention of following the business of a joiner and builder. Ill-health, however, which ultimately resulted in permanent lameness, caused his abandonment of this intention when he was about 21 years of age, and for the next twelve years he followed no occupation. In July, 1890, he formed the present Preston Building Trades Employers' Association, with an initial membership of about 30, and was appointed secretary of that organisation, which position he held at the time of his death. The membership of the Preston Association has for a number of years averaged about 175, practically comprising the whole of the employers in the building trade in the district. In the year 1894, he assisted in forming the old Lancashire Federation—the pioneer of the present system of National organisation—and was appointed secretary of that body in the same year. Four years later an amalgamation took place with the Manchester, Liverpool, and District Federations, under the present title of the Lancashire and Cheshire, and he was appointed secretary of the reconstructed society, which position he ultimately resigned on May 31st, 1911. On the re-formation of the old National Association of Master Builders, he was appointed secretary of the Northern Centre Council, and about the same time accepted the secretaryship of the Manchester and Salford Master Builders' Association (since reorganised to comprise all branches of the trade), which, in conjunction with the Federation, opened offices in Manchester. In 1904 he took a very active part in the formation of the Federated Employers' Insurance Association, Ltd., to deal principally

with the risks of building trades employers, and for about two years he was one of the directors, but resigned at the end of that period.

In 1904-5, Mr. Tomlison took part in the negotiations for the now established scheme of conciliation intended to prevent strikes and lock-outs in the building trades, and on its adoption he was appointed employers' secretary to the National, Northern Centre, Manchester, and Preston Boards, but relinquished the secretaryship of the National Board about four years ago, on the appointment of the present National secretary, and resigned the two Northern Centre secretaryships three years ago, in which he was succeeded by his partner, Mr. James Denver. Mr. Tomlison acted as secretary to the National Federation for a brief period during the interval prior to the appointment of Mr. A. G. White, but was prevented by a very severe illness from attending the annual conferences held in Dublin during that period.

In the year 1910 he formed his business into a company under the title of John Tomlison and Co., and took into partnership his assistants, Mr. James Denver, who has succeeded him in one or two of his secretarial appointments, and Mr. Sidney Elston Rigby, nephew of Mr. Tomlison.

The funeral, which took place at Walton le-Dale, near Preston, on Tuesday, January 9th, was attended by several representatives of the various organisations with which Mr. Tomlison had been so long associated.

Mr. Bloomfield Bare, F.R.I.B.A.

The death took place on Monday of last week, at his residence in Huskisson Street, of Mr. H. Bloomfield Bare, F.R.I.B.A., the well-known Liverpool architect. Mr. Bare was an enthusiast in the promotion of the higher interests of his profession, and took every opportunity of impressing upon the public his architectural ideals. It is now nearly thirty years since Mr. Bare commenced practice as an architect in Liverpool, after receiving his professional training in the surveyor's office of the London and North-Western Railway. For five years he was in partnership with Mr. H. L. Bethwick, architect and surveyor, and it was during this time that Mr. Bare acted as secretary of the Liverpool International Exhibition of 1886. Leaving England, he took up residence in Philadelphia, U.S.A., where he practised as an architect, only returning to this country some seven or eight years ago. He immediately resumed his artistic activities, and associated himself with the organisation of the Art Workers' Guild. Mr. Bare was also a member of the council of the Liverpool Architectural Society.

Mr. William Hall.

The death has occurred of Mr. William Hall, head of the firm of Messrs. William Hall and Son, builders and contractors, by whom many notable buildings in Liverpool and Bootle have been erected. Mr. Hall was seventy years of age, and had been in business as a contractor in Liverpool for nearly half a century. A member of the Liverpool Master Builders' Association for very many years, he was in 1894 president of the Association.

Mr. W. B. Huntington.

Mr. W. B. Huntington, wallpaper manufacturer, of Worcester, who died on November 13th last, left estate which has been proved at £334,335 gross.

SOCIETIES' MEETINGS.

SOCIETY OF ARCHITECTS.

The third ordinary meeting of the Society of Architects for the session 1911-12 was held at 28, Bedford Square, W.C., on Thursday, January 11th, Mr. G. A. T. Middleton, A.R.I.B.A., past vice-president, in the chair. Ten candidates for membership and ten for studentship were accepted. Mr. John Darch, F.S.I., then read a paper on "Illumination as a Study for Architects," which was illustrated by diagrams and lantern slides.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

A general meeting of this society was held in the society's room at the Leeds Institute on Thursday evening, January 11th, the President, Mr. S. D. Kitson, F.R.I.B.A., in the chair. An interesting paper was read by Mr. G. C. Workman on "Reinforced Concrete Applied to Buildings." The lecture was illustrated by many slides showing both constructional problems and architectural treatment of interiors and exteriors. The lecture was followed by a discussion on which many practical details were debated upon. A vote of thanks was passed on the motion of Mr. G. S. Crundy, seconded by Mr. W. H. Thorp, F.R.I.B.A.

INSTITUTE OF ARCHITECTS OF IRELAND.

A meeting of the Council of this Institute was held at No. 31, South Frederick Street, Dublin, last week, the President, Mr. A. E. Murray, R.H.A., F.R.I.B.A., in the chair.

A highly satisfactory report from the Publication Committee was received and adopted. A vote of thanks to Mr. Allberry, hon. secretary to the committee, was passed by the Council.

A report from the Professional Practice Committee in connection with the importation of shopfronts was received and adopted.

The Standing Committee were appointed as follows: Professional Practice—Messrs. W. Kaye-Parry, F. Batchelor, L. O'Callaghan. Arts Committee—Messrs. G. C. Ashlin, W. A. Scott, G. P. Sheridan. Publication Committee—Messrs. F. Hayes, R. C. Orpen, J. H. Webb. Examination Committee—Messrs. H. Allberry, R. C. Orpen, F. G. Hicks.

MESSRS. THOMAS PARSONS AND SONS' STAFF DINNER.

The annual dinner of the staff of Messrs. Thos. Parsons and Sons, the well-known varnish and colour manufacturers, took place on January 6th, at the Horse-Shoe Hotel, Tottenham Court Road. More than sixty were present, and telegrams were received in the course of the evening from Mr. C. Withers, chief of the London office, and several of the country travellers, regretting their inability to attend.

The chair was occupied by Mr. P. Gilliard, the senior traveller present. The toast of "The King" having been honoured, Mr. Gilliard proposed the toast of "The Firm," coupled with the names of Mr. George and Mr. William Parsons. He remarked that the outside representatives of the firm, of which he was proud to count himself one, had every good reason to recognise its prestige. It was a very great thing to serve a firm with such a

reputation as that of Thos. Parsons and Sons.

Mr. V. W. Theobalds, the works manager, responding on behalf of the firm, said it would be a great mistake to suppose that because the business had been running for more than a hundred years its vitality showed any disposition to decline. Quite the contrary: it was thoroughly up-to-date, enterprising, and full of force, vigour, and vim. There was a large and ever-increasing staff of travellers, ready to go anywhere—they went to a good many places already. He had not heard that one had reached Greenland's icy mountains—perhaps varnish would be no good there—but at least one had visited India's coral strands, and had come back with a nicely filled order book. He referred, of course, to Mr. Herbert Lloyd, who was going out again very shortly; the best wishes of all present would go with him. He was speaking on behalf of the partners in the firm, who were unable to be present, and he was sure that in saying they could not be better served by any staff he was only expressing their feelings; he knew they fully realised all the efforts made by the staff on their behalf.

During the evening, the gathering also drank the health of the chairman, Mr. P. Gilliard; Mr. C. Withers, to whom a telegram was sent, expressing deep regret at his serious and continued indisposition; Messrs. A. G. Mercer and W. H. Pantlin, whose organisation of dinner and programme were much appreciated, and Mr. J. Bowden, the employee longest in the service of the firm.

An excellent musical programme, supplied entirely by members of the firm's staff, closed the evening.

The Replanning of Delhi.

It is stated that the Indian Government has practically decided to employ the services of a town-planning expert from Europe in connection with the alterations at Delhi involved in the change of capital.

The London Labour Movement.

The management committee of the London district of the Amalgamated Society of Carpenters and Joiners, as has already been announced, have given notice to the council of the London Master Builders' Association of demands for an increase of 1½d. per hour in wages, double pay for overtime, and a reduction of summer hours from 50 to 47 a week. This is part of a widespread movement for improved conditions of labour in this branch of the building trade, and notices to expire during the course of the present year have been tendered in thirty districts of the country, including Ireland.

King Edward Memorial.

Full-size designs and models are being prepared for the consideration of the King Edward Memorial Committee, which is to meet specially for the purpose about the middle of February. The committee allowed Mr. Bertram Mackennal the sculptor, and Mr. W. E. Lutyens, the architect, a period of three months, which to complete this part of the work and the progress made justifies the expectation that the committee will by the time named have before them everything necessary to enable them to come to a decision. When completed, the model will show the whole plan of the memorial which is to be placed in the Brock Walk in the Green Park.

THE ARCHITECTS' & BUILDERS' JOURNAL.

WEDNESDAY,
JANUARY 24th, 1912.

Volume XXXV,

No. 888.

DOORWAY IN THE RUE DES ARCHIVES, PARIS.

This doorway dates from the seventeenth century, and is a delightful example of French work; sober in expression, pure in style, firm in detail, and refined in proportion.

DESIGN FOR A SILVER-MOUNTED ROSEWATER EWER. BY ALFRED STEVENS.

THE ARCHITECTS' & BUILDERS' JOURNAL.

JANUARY 24th, 1912.

CAXTON HOUSE, WESTMINSTER.

VOLUME 35. No. 838.

NOTE : The List of Contents will be found on page IV. of the front advertisements.

Architectural Education in England and America.

THE current number of the "Journal" of the Institute of Architects contains the announcement of the first instalment of the competitions which are to form an alternative scheme to the "Testimonies of Study" for the Final Examination or Associateship of the Institute. The system adopted is that six alternative problems in design are to be set by the Board of Architectural Education in each year; three of them to be announced in January of each year, and three in July. The results of the work on these problems as tests of proficiency will come into operation in November next, and after the end of the year 1913 the existing "Testimonies of Study" will be abolished. The position in the interim does not seem quite clear, or is not quite clearly put, but we presume it means that up to the end of 1913 candidates for election may either rely on the existing scheme of "Testimonies of Study," or may take up the new scheme of treating the special subjects set; but that after the end of 1913 there will be no further option, and the treatment of the specially set subjects will be compulsory. In the meantime this leaves the examination of candidates to go on under two different systems at the same time, which seems rather to confuse the situation; but we presume it was thought that so radical a change in the method of examination could not be introduced except by degrees. We should have thought it better to give ample notice of the date when the change would be adopted, and then adopt it at once and entirely. It may be expected, however, that the majority of candidates during the present year will adopt the new system, because they will probably think (rightly or wrongly) that in doing so they will be more favourably regarded by the examiners.

Although three subjects are set in January and three in July, it is not intended that candidates should have the whole half-year to work them out in. They are all related together "for the convenience of candidates," which means probably that candidates may have an early opportunity of knowing what will be expected of them, and of directing their thoughts and studies towards the subjects they intend to take. But dates are fixed for the ending in of each subject; Subject I. on February 29th; Subject II. on April 30th; Subject III. on June 30th; and the same system will be continued in the following half-year, with the subjects announced in July. We do not quite see the motive for this, unless it is the convenience of the examiners, who may thus consider one subject at a time and have done with it; unless it is supposed that it is better for the candidates to be encouraged to concentrate their minds on one subject at a time, which may perhaps be the case.

The subjects set for the candidates run in pairs, so to speak, and seem to have been arranged so as to provide each case for an artistic and a practical study. No. I. consists of a design for a monument, not to cover more than 100 square ft., to commemorate King Alfred's re-founding of London one thousand years ago, for a public place in the City; which place may be rather difficult to find, if it is to be within what is usually understood as "the

City." The centre of Finsbury Square, or Finsbury Circus, might perhaps come within the definition. The drawings are all to be $\frac{1}{2}$ in. scale and shaded. The nature and number of the drawings seem to be left to the candidate, but as this is not a competitive examination but only for proficiency, that is not of much consequence. The stipulation for $\frac{1}{2}$ in. scale is a good one; on that scale, details of a design have to be carefully considered, and an effect cannot be got by mere effective sketching on a small scale. It is surprising, in what are called "sketch competitions," what a difference there is between the effect produced by a small sketch elevation, and the same elevation when it comes to be worked out by the same hand to a larger scale. The other subject, accompanying this, is a terrace of five houses of 20 ft. frontage for a small watering-place, which will show what the candidate can do in the planning of a small street house. These are to be $\frac{1}{8}$ in. scale, with a detailed construction of one house to $\frac{1}{2}$ in. scale. The King Alfred monument ought to prove an interesting and suggestive subject in the purely artistic treatment of architectural design.

The second subject consists of a large monument "To an Explorer," to be placed against the wall of a public building; another $\frac{1}{2}$ in. scale subject. A limit of width should have been given, as a limit of area was given in the first subject. The accompanying subject for No. II. is a cloister, with an external entrance gateway or tower round a courtyard of a collegiate building, 100 ft. square. It should have been stated whether the 100 ft. measurement includes or does not include the width of the cloister walk; probably it means the width of the space exclusive of the cloister, but it would have been better to have this precisely stated. This is to be $\frac{1}{8}$ in. scale, with a $\frac{1}{2}$ in. detail of "the construction of one bay," so that this provides for the practical constructional element in the drawings. No. III. subject is a detached ball-room to a large country house, connected with the house by a covered way; "the decorations should be specially considered"; all in $\frac{1}{2}$ in. scale drawing, with a detail of the decorations. The scale of this detail should have been specified; this is again a slight want of precision in the instructions. This is a good subject for drawing attention to the treatment of internal decorations, which in such cases are too often not done by the architect, but entrusted to a firm of "decorators." The more architects give their attention to this matter of interior decoration the more likely they are to keep it in their own hands. In connection with this we may suggest that one of the remaining subjects might very well be given to the designing of a suite of furniture for a room. The second subject, together with the ball-room, is a landing-stage to a river or lake, with a restaurant; drawings to show complete construction $\frac{1}{8}$ in. scale and $\frac{1}{2}$ in. scale, but it is not stated what the $\frac{1}{2}$ in. is to include. We fear this want of precision will leave the Institute Secretary under the necessity of answering a good many questions.

That is the only criticism to be made; the subjects in themselves, so far, seem to be very good ones, calculated to test the candidates both in their artistic and practical proficiency. Candidates for the Final Examination must submit designs in answer to at least four of the six problems; the three already set and the three further ones to be set in July. We presume that means that each pair of subjects

is considered as one; another point which is not made as clear as it ought to be, and about which there will probably be questions asked. It will be interesting to see what the remaining three problems will be. We may suggest one or two. A design for a terraced garden, in plan and section, including the plan of the front of the house with which it is connected. A design for a stone bridge in a park, for a stated width of waterway, width of roadway, and height of the crown of the bridge above water-level. A design for an organ-case, for an organ of a specified size; a subject capable of much better treatment than it generally receives, and which is too often left to the organ-builder. Look at the grand treatment of some of the eighteenth-century German organ-cases, which are really works of art; we never see such a thing in modern England. Some of the eighteenth-century English organ-cases are finely treated, but the English organ of those days was too small an affair to vie with the great German erections. Nowadays we have organs of great size in town halls, but we rarely see a really fine organ-case; and there are few subjects more suggestive. To go to a very different class of subject, a great warehouse built in reinforced concrete might be a good exercise both in design and construction. But the new scheme, so far as it has gone, seems to promise a great deal in the promotion of architectural design in the future.

A recent issue of the "American Architect" contains the long Report of a Committee on Education of the American Institute of Architects. It treats the subject of architectural education in a very broad and comprehensive spirit. The general tendency of the Report seems to be that it has been very difficult to get the American architectural student to take any interest in architectural training except in regard to that kind of study which may lead to the making of money; what the Report calls "bread-and-butter courses," the object of which was "to make the student a wage-earning animal at the earliest moment and in the line of narrow, intensive activity. The result has had its limitations so far as the making of character and the development of culture and education are concerned." Within the last five years, it is said, there has been rather a reaction against this view of architectural education, but there seems to be still a complaint of the want of a broad and comprehensive interest in architecture. What is specially complained of is the want of interest in architectural history:—

"We have found that in the extension courses that now exist—except in the case of Boston—lectures on history are the least popular; this year, for example, New York could produce only one man to take ancient architectural history in the evening classes, and but five for the mediæval history, while twenty-four students took architectural drawing. This is all very natural, for the driving motive is quick increase of pay; but it means, if continued in, simply one thing, and that is an overplus of clever but essentially ignorant architectural draughtsmen, who will remain such to the end of their days, and a dearth of men of sufficient cultivation and intelligence to become efficient practitioners of architecture."

Is not this partly the fault of the American public, the clients of the architects? When we read the statement, as we did not long ago in an American article, that a man who proposes to erect a new building wants the drawings in a week, and that if one architect will not undertake to furnish them in that time he will go to another who will, it is not surprising that the faculty of quickness in drawing, of producing something presentable in the shortest possible time, comes to be unduly valued. This demand for rapid designing and building is creeping over us in England too, though it has not arrived at the aggravated stage which seems to exist in America; and both the English and American public need to be taught that good architectural design is not a commodity which can be produced in a hurry. Designing done against time can generally mean only the putting together of stock elements in architecture which are kept ready to hand; the most certain way of producing common-place work, the highest

merit of which can only be to look fairly presentable. On the other hand, it is rather curious to find an American education Report lamenting the want of interest in architectural history, just at the time when some of our own most thoughtful teachers are saying that too much attention is directed to history, and that it is owing to this that our contemporary architecture becomes a mere echo of the past. The truth is that historical knowledge is of the greatest importance provided the right use is made of it; without it no one can fully realise and feel what a great and endless subject architecture is; but the knowledge should be used to widen the outlook, to enlarge our ideals, not to furnish matter for mere realistic imitation.

Another subject of complaint in the American Report is that in some of the schools no consideration is given to modelling, which, as is rightly observed, "is the best possible method whereby students may be brought to think in three dimensions instead of in two." In our own Architectural Association schools modelling, we believe, takes a place, though perhaps not a very large one, in the course of instruction; and in regard to this point it may be suggested whether one of the subjects in the new Institute examinations for the "Final" might not include the production of a model of a design. The introduction of such a requirement would have a very important influence in reviving the practice of showing a design in the form of a model; a practice so largely used by the Italian Renaissance architects.

Students' Drawings at the Institute.

THE designs for the Soane Medallion are not up to the best average by any means. The subject given was a guildhall to seat 1,200 on the floor, with a smaller hall to seat 400, and a banquetting room for 200; the building to be regarded as situated in a public park, 100 feet back from the road; the drawings required being a plan of each floor, two elevations, two sections, an exterior perspective, and a street of details to $\frac{1}{2}$ -inch scale.

It is a large scheme for students to undertake, and much more serious work has to be done to win the Soane than is sufficient for the Royal Academy students to win the larger prize of 200 guineas; the Academy Travelling Studentship being, in fact, in most years, a reward rather easily earned. For the Soane some very elaborate sets of drawings have been sent in, but hardly any of them can be regarded as at all a satisfactory solution of the scheme. One thing that strikes us is the tendency to treat the main hall as a wide area—a circle, an octagon, or a square. This is the worst type of plan for an assembly hall where people are to hear anything, speech or music, uttered from a platform. The circular form promotes echo, and both that and a square form spread the audience out too much at the sides. The motive for the adoption of these types of plan is evidently the desire to get in a dome as the principal external feature, and perhaps the desire to show ingenuity or invention in planning, in the manner of working the subsidiary rooms around the central circle or octagon. Thus "Guild" shows his large hall as a square placed diamond-wise, with an apse at each point, and the two smaller halls parallel with two of the sides. The exterior perspective, with semi domes over the four apses, abutting against the central dome, looks very awkward. "Circle City" makes a better disposition of masses, the small halls extending as a front block right and left of the entrance, with the circular Guildhall in the rear. "Ou Topos" gives a Greek cross plan for the Guildhall, with the two smaller halls parallel with the two opposite recesses of the Guildhall, with a vista across; but the Greek cross is one of the worst forms for a public hall, in point of convenience and hearing. "Black Fish" has a circular hall in the centre, with subsidiary halls and other rooms projecting as four equal arms from it, in cross form; there is nothing to recommend it in plan, but the exterior perspective is quiet and in good taste, though a little too much like a prison. The other named already show no merit whatever in exterior treatment.

"Vista" seems the only design to which the medal could possibly be awarded. The author has adopted the proper form of a long rectangle for the guildhall; the corridor communication is well arranged, as also the cloak-rooms for ladies and gentlemen in connection with both the main entrances (an important point often neglected or muddled in student plans); the interior treatment of the large hall is good, and the arrangement of organ and orchestra much better than is usually seen. The architectural treatment is adequate in detail, but it would have been much better if the author had omitted the tower.

Among the other designs, "Fraternity" seems so enamoured of the square that he makes all his halls, large and small, complete squares. "Ship" (device) shows the best plan next to "Vista"; his circular columned "staircase hall" hardly deserves the name, as there is no staircase in it, but two rather narrow staircases leading out of it on opposite sides, which would be somewhat ill-lighted. "Vitæ" adopts an octagon with equal sides for the guildhall, with one of the smaller halls, and various committee rooms, planted against the sides of the octagon; there are also four reception rooms on different sides, but the banqueting hall seems to have been forgotten. "Experientia docet" shows a square guildhall, but otherwise a fairly good plan, though it is not good designing to make a banqueting hall architecturally balance two committee-rooms on the opposite side, merely by omitting the cross wall. A hall should show differently, in the architectural arrangement, from a couple of committee-rooms. The piled up central mass—a kind of Tower of Babel—is an effort to be sublime, but is out of place and useless.

We should not be surprised to hear that the Soane Medallion had been withheld this year; but if it is awarded, we should say that "Vista" is the only design which has any claim to it. (We are writing this notice prior to the announcement of the awards, owing to exigencies of going to press.)

The Tite prize is for the best design for a central courtyard of a Royal Exchange, covered by a roof. The average here is much higher than in the Soane designs, but the problem is a good deal easier. Here, again, there seems rather a tendency to adopt circular plans; one of them, signed "The Circle," is very clever as regards plan, with columns surrounding the interior, the spaces between which are occupied alternately by a niche and an entrance door into subsidiary apartments and offices. The author has adopted the Ecole des Beaux-Arts system of colouring and shading the floors and leaving the blocks of wall white; though it does not render a plan so readily intelligible as the English system of shading the walls dark. The roofing is a dome with round lights at the springing. "Centres" has also a circular plan, roofed by a dome with a central eye; there is a two-storeyed columnar order; it is good and correct, but not very interesting work. "Dum Spiro Spero," with a court in the form of a parallelogram, is superior to either of these; the details of the Roman Doric order and of the attic are beautifully and delicately drawn, and the whole set of great merit. The competitor who signs "φερω-κουρητε" presumably means his design to be executed in reinforced concrete, but the details, though clever, do not show any particular fitness for execution in that material; a serious fault in the design, taken as a whole, is that the three domical ceilings have no architectural relation to anything in the plan. The only other one we need mention is that signed with the device of a Red Lion. This is a rectangular court with a very good and architecturally conceived plan of the corridors; the elevation shows a rusticated basement with arched openings, surmounted by an order of coupled Corinthian columns; the detail sheet is a very good one. We are not sure that this is not the best fulfilment of the programme set.

There are some fine sets of measured drawings for the silver medal and ten guineas. "Arno" shows a very complete set of the church of Santo Spirito; "Sphinx" a small set of drawings of the gaim architecture of Cork prison;

There should rightly have been two r's in "φερω," or does he mean to make a pun by adopting the Greek verb "φερω"—"I bring concrete"?

and "Zeta" a very complete set of drawings of Compton Wynnyates, with the plan coloured to show the dates of different portions. If, however, the difficulty of measured drawings of this class counts for anything, the draughtsman under the odd motto "Shopeinshoudes" should have due credit for his set of drawings of the octagonal lantern at Ely, a subject the difficulty and complication of which might well have deterred a student from attempting to measure it up. It is done with great care and minuteness in showing the construction, and does high credit to its author.

The drawings for the Grissell Medal are not remarkable; unfortunately, they seldom are, this essentially practical prize apparently offering little attraction to architectural students. The drawings of the two applicants for the Owen Jones Studentship, Mr. Noel Leaver and Mr. G. W. Mason, it would be difficult to choose between; both show exceedingly good specimens of illustrated drawings from coloured subjects, polychromatic architecture, mosaics, etc., mainly from Italy. There is a large collection of sketches by candidates for the Pugin Studentship, but our impression from a necessarily brief examination is that they did not exhibit so large a proportion of good work as has sometimes been seen in competition for this prize.

The awards, announced at the moment of going to press, are as follows:—*Soane Medallion*, Certificate and £50 each: "Circle City," W. Friskin (London); "Antæ," P. de Jug (Leeds); *Owen Jones Studentship*, Noel H. Lever; *Pugin Studentship*, James Macgregor; *Tite Prize*, "Red Lion," Louis de Soissons (London, S.W.), Hon. Mention, "The Circle," T. H. Chalkley (London); *Grissell Prize*, "M-CM-XII," Thos. Braddock (Wimbledon); *Institute Silver Medal and 25 Guineas*—Essay—T. Harold Hughes (Aberdeen); *Institute Silver Medal and 10 Guineas*—drawings—A. E. Maxwell (London, S.W.); *Arthur Cates*, J. B. F. Cowper; *Godwin Bursary*, Geoffrey Lucas (London).

WHAT IS WANTED IN THE BUILDING TRADES.—III.

(Concluded from page 63 No. 887.)

TO resume consideration of the German method of professional training for master builders.

A short survey of the regulations in regard to apprentices, and the testing of journeymen and masters, will show the thorough way in which the organisation of the professional side of the building trade is carried out.

"Before anyone can undergo the test for Mastership in the building trade, he must be able to prove that he has undergone the test for journeymanship in one of the handicraft branches of the trade."

This provision of the Law of 1908 does not come into force until October 1st, 1913, and of course is not retrospective.

The guilds provide panels of members suitable to serve on commissions to which are confided the testing examinations for Mastership. The president of one of the higher Courts selects the commission from these panels. Appeals against rejection by the Test Commission may be made to the Courts within two weeks thereafter, but the Court must hear the guilds also before granting the appeal.

"The Law requires that the test must bring forth information as to the capability of the candidate for the sole conduct and cost-keeping of the usual work of the trade, as also to the possession of the otherwise necessary knowledge for the sole management thereof, and in especial to the book-keeping and cost-keeping required for its proper conduct."

The guild sets the questions to be asked, subject to the approval of the Ministry, which also regulates the formalities relating to the order and conduct of the test. Here are a few extracts from the regulations in force in Berlin and district (masonry and joiners' work):—

Tests for Candidates.

In making application to the Commission for a test, the

candidate has to refer to his present or late employment, write a short historical account of his trade experience, produce a certificate of having passed a journeyman test, also a certificate that since the expiry of his apprenticeship he has been engaged in the handicraft in question for at least three years, that he has become practically capable therein, and that he has spent a further two years as a leading hand therein. He must also furnish certificates showing what technical instruction classes he has attended.

If his preliminary statement satisfies the Commission, he is informed of the fact, and a date is fixed for test. Near relations, former employers, or partners of candidates are excluded from the Testing Commission. Not more than six candidates may be invited for any one day. Tests are held at intervals of six months generally.

A modest fee is required from each candidate, which goes to the guild that bears the cost of the fees paid to the examiners and other costs of these commissions. In certain circumstances fees may be remitted in the discretion of the Guild Council.

The test consists of an oral examination and the execution of a test piece of work, including the setting-out of a small design with description and estimate of cost, to a scale of $\frac{1}{100}$, together with some details of construction to a scale of $\frac{1}{10}$; also an estimate of the quantities and cost thereof.

The test extends over six working days of eight hours, and is designed to test fully the capacity of the candidate. It takes place under supervision of members of the Commission in a place set apart for the purpose.

The oral examination is directed to test the general trade knowledge of the candidate, his knowledge of simple book-keeping, and of the legal and other enactments affecting his trade. His knowledge of trade terms is tested by requiring him to describe fully the test-piece.

He is examined in calculations in regard to roofs and the corpus of buildings, with examples from current practice; his knowledge of statics and factors of safety being tested by simple examples in wood, stone, and iron building construction.

He is examined in foundations, their characters, and the method of dealing with various kinds, masonry and the usual constructional types thereof, the like for wood construction and for the general finishing of a building. His knowledge of materials is tested, also his general grasp of the theoretical side of the art.

Finally his knowledge of how to direct building work and how to deal with variations and admeasurement are tested.

The examination may be shortened for those who have passed a final examination at any State or State-recognised building school. A verdict is rendered within eight days. If a pass has been secured, a certificate records it; if the candidate has failed, he is told in what respect, and a delay is prescribed which must expire before he can offer himself for re-testing. It is only necessary to be re-examined in those points in which the candidate failed on the former occasion. A second rejection is final.

The possession of a pass certificate entitles the candidate after his 24th year to assume the title of Master, and to undertake the training of apprentices. In this connection the Builders' Guild of Berlin has prepared an elaborate syllabus of the work in which a student should be prepared before presenting himself as a candidate for the Mastership test.

And the work of the guilds does not stop here, for they consider that the proper training of those who have to follow on is their most important work.

The indentures of apprentices is the foundation of the training. The apprentice must serve at least three years, every one must be bound, and this fact notified to the Guild, which thenceforward keeps track of the apprentice.

The employer of an apprentice is legally bound under penalty to present him for his journeyman's test. He must not only present him, but do his best to get him satisfactorily through it.

An apprentice who fails in this test cannot advance any further in his profession. The tests are bi-yearly, and on

similar lines to those already described, but on a lower plane of acquirement.

The test comprises two parts, theory and practice; the practical part is for handicraftship, while the theoretical part relates to the preparation, handling, and care of materials used in building, also to the characteristics of good and bad materials and the use of machines.

All these requirements imply the provision of

Proper Building Schools,

and this has not been neglected. There are various grades of schools, such as:—

(1) Schools preparing pupils to act as master builders and contractors; (2) schools giving instruction suitable to those who will be employed in offices and on works as draughtsmen, foremen, etc.; and (3) schools for the preparation of those who intend to become technical employees under the Government, railways, and public bodies, on staff positions.

The schools are mostly State-provided and controlled. They receive pupils from the age of sixteen who have received a primary education, selection being by examination. Adult mechanics are however admitted to certain classes. Elaborate syllabuses set forth the courses of study, and test examinations are held at their conclusion. Courses of lectures on the higher branches of the building art are given in Berlin for master builders.

Conclusions.

It must be evident from the foregoing that in Germany the art of building is held in esteem, and that the title of Master Builder is intended to mean a real professional standing and a higher level of attainment than commonly obtains here.

This country has been learning a good deal from Germany during recent years, and it seems as though there is here another opportunity to acquire the knowledge which pays, and to turn it to account for the cure of the evil which always afflict the building trade, but are especially in evidence when times are hard, by establishing a thorough system of technical and professional training on similar lines to those in force in Germany, so that everyone who professes to be a builder may be expected, in the near future, to have qualifications equal to the demands of one of the most exacting, varied, and progressive industries.

It would seem that to the Institute of Builders, an old established and respected institution, a great opportunity is given. If that body were to lay itself out to extend its influence by means of county branches, and, after awakening builders generally to the need for better professional training, proceed on similar lines to those which have been pursued by the institutes of other professions, so that Fellowship it should mean a high standard of professional attainment, it might eventually control the professional training for the building trade as effectively as the professional training of lawyers, medical men, and engineers is controlled; and to the mutual advantage of members of the building profession and the public whom they serve.

The whole educational system in regard to this industry also needs overhauling. Co-ordinating and proper building schools and colleges should be established in important centres. And when the building trade can show that it provides a thorough training and testing of those it admits into its ranks, it will have a good case for going to Government for that legal protection which is the ultimate need of all professions.

The first thing required is the raising up of an examination of what might be done to improve the professional qualifications and standing of builders as a class, in which connection the following extract from a book by Mr. Hyndman may be cited with force:—

"It is the conception of what shall be that breathes life into what is. The mere machinery of politics [the writer would substitute "organisation"] is useless without the forceful energy of intelligent idealism to provide the motive power."

[The opinions of our readers on this subject are invited.]

THE WORK OF ALFRED STEVENS.

BY E. F. STRANGE.

The reputation of Alfred Stevens has been steadily advancing since his death, and to-day his work, much of it in a sense architectural as well as monumental, is more widely, if not more highly, appreciated than ever before. Mr. Strange's admirable synopsis of it, and the accompanying illustrations, will therefore be cordially welcomed.

A LECTURE on the work of Alfred Stevens was delivered by Mr. E. F. Strange, Assistant Keeper, Victoria and Albert Museum, on Monday, January 15th, before the Architectural Association.

Mr. Strange said he would first run over the main facts of Stevens's life. Stevens was born on December 30th, 1817, at Blandford, and was the son of a house painter. He began to copy pictures at the age of ten, and he painted a wonderful portrait of himself, reputedly at the age of fourteen years. He was introduced to the Hon. and Rev. Samuel Best, by a Mr. Henry While or White, who described himself as "fond of the art of painting." There was some doubt about the name, but White was probably correct: Best was Stevens's "principal benefactor," and he sent him to Italy in 1833. Stevens went to Naples first, and he himself said that he spent eight years at the Academy at Florence—in two periods of two and three years, with an interval between. He arrived in Florence in the autumn of 1836. Stevens promised to write every month, but a whole year passed without any tidings from him. Whereupon Mr. White wrote to the Director of the Academy, conveying the anxiety of Stevens's parents, and enquiring whether Stevens had met with an untimely end. The Director, in his reply, said that Stevens had been working there, but not as a student of the Academy. He had been studying in the life school and had made a considerable number of copies of pictures. At that time, said Mr. Strange, he was away with an American sculptor named Kinloch.

In his book on Stevens, Stannus said that he went to study Salvator Rosa, but Stevens was known subsequently to have changed his mind. During the time he was in Italy he managed to see much, to visit most of the towns, and to study most of the work. A number of Stevens's Italian studies and sketches remained, said Mr. Strange, and of these a landscape in water-colours, and a study of rocks at Pozzuoli, were shown upon the screen. Among a miscellaneous collection of drawings and sketches acquired by the South Kensington Museum, said Mr. Strange, were found some battered fragments of studies which he believed were those submitted by Stevens in the competition for the fresco decoration of the Houses of Parliament. A condition of the competition was that competitors should supply an example actually worked in the material. That by Stevens was a scene from Richard III. Copies only of this were in existence, the originals having been destroyed. Other fragments of drawings prepared most likely for the earlier competition of 1843 had also been discovered. These were of figures for four corners of a circular composition, illustrating certain portions of Milton's "Paradise Lost," and Spenser's "Faerie Queene." Stevens, after his return to England, gave evidence on a committee of enquiry into the training given at the School of Design. Stevens was master

here only for two years, and he left in sympathy with the headmaster. He said that there was but one course in the Academy—a course intended for painters, and consisting mainly of the study of the human figure. There was no instruction in design. "Pupils," said Stevens, "generally enter the Academy with the intention of becoming artists; the study of the human figure is therefore the great feature of their education. Some of these, towards the completion of their studies, are by their natural disposition or by circumstances led to turn their attention to ornament with their already acquired knowledge; but little special study is sufficient to make such men excellent ornamentalists. In this manner Italian designers are made."

At the Italian academies, continued Mr. Strange, the average period of studentship was ten years. In the course of the enquiry this point also was considered. One of the witnesses (Mr. Townsend) had said he thought two years long enough for the acquirement of a sufficient degree of technical skill for the purposes of a designer. Stevens was asked his opinion. "If," he said, "by technical skill he understood the power of being able to copy well, either in drawing or painting, a form which is put before you, it appears to me that when a man has attained that he has finished his studies."

Again: "I think that technical skill depends upon the knowledge of a pupil. I think a pupil will never be able skillfully to put down, either in painting or drawing, any form which he is not

perfectly acquainted with. I hardly think that manual dexterity comes from anything but from a boy being very certain in his own mind what he is about to do." He said that a preliminary school course of four years "at least" was necessary for the young designer.

In 1847, continued Mr. Strange, Stevens obtained a commission to decorate a portion of Deysbrook House, in West Derby. The story was told that Stevens having postponed the work again and again, at last set off and arrived a fortnight before the end of the time allowed for its completion. The three rooms were finished in time, and remained perhaps the most remarkable examples of mural decoration in this country. Whether or not it was a fact that the work was executed at so rapid a rate, he did not know. Many careful studies for the decorations were now in South Kensington Museum. (These drawings were then shown upon the screen.)

Stevens's design for the gates to the Geological Museum, in Jermyn Street, were unfortunately never carried out. These remarkable gates were based upon his Florentine studies.

When Stevens returned to England it was his intention to become a portrait painter—or, at least, a painter; but he drifted instead into various forms of design. (Examples of his work, such as a rose-water sprinkler, a table centre, Indian knives, and candlesticks, were then shown.)

His use of the human figure in industrial designs was one of Stevens's strongest and most interesting characteristics. No Englishman ever made use of it to greater advantage. He was particularly fond of arranging figures round a central stem, and many beautiful candlesticks designed in this way were now in South Kensington Museum. Much of Stevens's industrial work was, in the speaker's opinion, rather over-elaborated, though the ornament was invariably executed

PORTRAIT OF ALFRED STEVENS BY WILLIAM ELLIS.

(From the Original Medallion owned by Messrs. Hoole, of Sheffield.)

with wonderful precision and skill. His designs for street lamps were not very well known; but these all showed a serious attempt to beautify a purely utilitarian object. He did not overload them with ornament, and he seemed to have accepted the conventional form of lamp at the top.

In 1850 Stevens went to Sheffield and worked for Hoole and Son. For this firm he designed fireplaces, grates, stoves, and other objects of utility, all of which he invested with what hitherto had been unheard-of importance. These designs created quite a sensation at the Exhibition of 1851. (A design for a grate with two fire dogs, the original of which is now in the Victoria and Albert Museum, was then shown.)

slide of the plaster model of the door-knocker for Dorchester House, Mr. Strange said that the work, as executed in bronze, had lost much of the effect of the original design. This happened so often in Stevens's work; many of his designs which had been carried out failed to fulfil the expectations raised.

Dr. Holford gave Stevens the commission to decorate portions of Dorchester House, not in 1853, as was stated by Stannus, but in 1856. Stevens at that time (a year before the Wellington Monument controversy) was not such an unknown man as it was customary to believe.

A well-known contemporary periodical contained the following appreciative remarks:—

circumstances there is no fear as to the result; nor, we should think, that all the apartments will not eventually be placed in Mr. Stevens's hands. . . . We have often had occasion to speak of Mr. Stevens's work in ornamental art with high praise. The style in which he is strongest is Italian (so called), the most appropriate, on the whole, for English houses of the class of Dr. Holford's; yet he is no servile copyist—his compositions, though fully imbued with the full and fervid character of the Italian school, are yet no mere *refaccimenti*—he thinks for himself. In any other European state he would have achieved by this time a much wider celebrity than has yet fallen to his lot. This arises from no shortcomings on his

DESIGN FOR THE DECORATION OF ST. PAUL'S CATHEDRAL, BY ALFRED STEVENS.

Sincerity, thoroughness, and a genuine love for his work, continued Mr. Strange, distinguished all Stevens's details of household furniture; and if they had been required for his greatest efforts they could not have been more brilliantly conceived. (Among the examples now shown were panels in blue tiles for one of his stove designs—at present in the Tate Gallery—a pair of finger plates for folding doors, and the lion which was made for the British Museum railings, and which was also included in the Wellington Monument in St. Paul's.) Showing a

"We are much rejoiced to hear that the internal decoration which is now about to enhance and complete the structure [Dr. Holford's House, in Hyde Park] is likely to be in the hands of an Englishman—and of one who, we are quite sure, will perform his part worthily. Mr. Stevens, of Kensington, is already entrusted with the decoration of the dining-room, with respect to which he is given a *carte blanche*, and this with the full concurrence of the architect (Vuliamy), which speaks well for that gentleman's liberality of feeling. Under these

part, but from the fact of there being no proper status yet for an ornamentalist in this country—at least, for a British one. We trust, however, that will ere long cease to be the case, and that ornament—without a strong feeling for which, we reiterate, there can be no true union of the arts—will have its rank acknowledged. The success predicted in the present instance will give it aid, . . . inasmuch as our impression would not hesitate to vent Mr. Stevens's powers in his own style by the side of those of any living ornamentalist.

alist, and this notwithstanding that he may be generally known to the public by the assistance he has given in the best class of ornament connected with stoves and grates than by his other compositions. . . . As regards Mr. Stevens, we believe him equal to any efforts in high-class Italian ornament; for which he possesses also the peculiar advantage of being equally successful in his efforts of colour as in those of form, thus grasping a far wider and more varied range than would otherwise be the case."

Stevens's work for the 1851 Exhibition—continued Mr. Strange—added much to his reputation, and when he came almost at once to the performance of some of the great work upon which his fame chiefly rested, he was by no means an unknown man. It was rather uncertain whether Stevens had ever exhibited at the Royal Academy. He (Mr. Strange) had found by consulting the entries in the Academy Catalogue for 1856 that a "Mr. A. Stephens" had exhibited a drawing of the interior of a church. This might conceivably have been Stevens. He was personally inclined to think it was, because this was the only exhibitor that year who failed to communicate his address. This seemed to point directly to Alfred Stevens.

Continuing, Mr. Strange said he had tried to obtain admission to Dorchester House, but had failed. The privilege was perhaps not unreasonably denied, but one could not help wishing that, wherever possible, Stevens's work might be made accessible to the public. Steps should certainly be taken for the preservation of Stevens's own house at Havering Hill, and of the decorations at Deysbrook. It should be possible to do something in both cases.

Stevens was associated with Digby Wyatt in the design of a pavilion to be set up at Paddington Station, but the work was never carried out. For the Crystal Palace he did two ceilings in the Italian Courts; what would be the future of these was a matter for serious consideration. Another outlet for Stevens's energy was the designing of majolica ware, some of which had been acquired by the Museum in 1864. At South Kensington he was responsible for the tables in the refreshment room (except for the marble tops), and he also prepared the design for one of the large heating coils. Stevens did not do anything in the decoration of the Museum; this was chiefly done by Sykes and his fellow pupils. Stevens would have nothing to do with the decoration of the old part of the Museum. He would look in during the evenings when the designs were being prepared, converse for a little, and perhaps make a few suggestions, but nothing more.

It might be safely asserted, continued Mr. Strange, that no finer design for a certificate had ever been prepared than that which Stevens designed for the International Exhibition in London, 1862. The wood-engraving was made by W. J. Linton, a pupil of Stevens while he was master in the School of Design. Sketches by Stevens for the Memorial for the 1851 Exhibition were then shown. The competition was held in 1857 and settled in 1858, after a particularly acrimonious discussion. Stevens's model was now in the Museum. It represented four continents joining hands round a central shaft, and showed the finest form that this favourite motif of Stevens's had ever reached. A series of bas-reliefs ran round the shaft, beneath the soffit of the cornice, the size of

which member was perhaps not excessive when it was regarded as a protective shelter for these bas-reliefs. It was probable, also, that a bigger base would have been provided than that which appeared in the model.

The figures on the Dorchester House fireplace, thought Mr. Strange, were the second best that Stevens ever made. To him, however, they conveyed an impression almost of discomfort; as a design, nevertheless, the execution was marvellous.

[The plaster model of this fireplace, now in the Museum, was shown upon the screen, and among the many other examples of Stevens's work that were shown and described by Mr. Strange were the following:—Decorations for St. Paul's Cathedral; alternative sketch designs; detail tracing by Stannus for portion of filling of the dome; studies or models for Isaiah, Jeremiah, and Daniel, and a sketch for Joel and Jeremiah, and many sketches and studies of details.]

Mr. Strange then turned to the Wellington Monument, showing a sketch design, a perspective, a model, a view of the completed monument, the figures of Valour and Cowardice and of Truth and Falsehood, and models and sketches of the

equestrian figure. For comparison with this last, Mr. Strange showed the statue of Gattamelata, Padua, by Donatello.

Within the short space of time at his disposal, Mr. Strange said, it was only possible to give but a brief sketch of the history of the Memorial to the Duke of Wellington. A sum of £20,000 was left over from the amount voted for the State funeral of the Duke, and with this money, combined with a sum of £5,000 which had previously been voted by Parliament for the purpose, it was proposed to set up a memorial in St Paul's Cathedral. Sir William Molesworth, then First Commissioner of Works, invited four sculptors—Baily, Foley, Gibson, and Marochetti—to compete for the commission. Only Baily and Foley competed, and their designs were rejected by the Commissioner, who refused to consider offers to modify them to his satisfaction. The immediate result was an acrimonious public discussion, inspired by the conviction in the minds of many artists that it was intended to give the work to the Court favourite—Count Marochetti, the "Baron Marofatti" of "Punch" of those days. Sir Benjamin Hall, Molesworth's successor in office, was bombarded with memorials and letters demanding, not

A PORTION OF THE STUDY FOR THE CARTOON OF JOEL (DESIGN FOR THE DECORATION OF ST. PAUL'S CATHEDRAL), BY ALFRED STEVENS.

DESIGN FOR A LAMP STANDARD.
BY ALFRED STEVENS.

unreasonably, the employment of British artists. A new competition, open to artists of all nations, was then instituted, and it was arranged that models should be publicly exhibited in Westminster Hall before a decision was arrived at. The conditions were announced in September, 1856, a plan being issued with them, showing the proposed situation of the memorial under one of the arches on the north side of the nave of the Cathedral. For this competition Stevens entered. The Victoria and Albert Museum fortunately possessed not only his original sketches on the plan issued by the Office of Works, but also the actual model sent in for the competition and included in

the exhibition at Westminster Hall, which opened on July 20th, 1857, under the motto, "I know but of One Art." This was No. 18 of the 83 models which complied absolutely with conditions designed to secure equality of judgment. The committee appointed to make the awards consisted of Lord Lansdowne, the Rev. H. H. Milman (Dean of St. Paul's), Lord Overstone (a financier), General Cust, Mr. Gladstone, and Mr. Cockerell; the Committee thus representing both Houses of Parliament, the Church, the Army, High Finance, and Architecture. The Committee reported that "Mr. Cockerell, the only one of the appointed judges professionally connected with the arts—though we have derived from him valuable assistance and information in the progress of the examination—has declined taking a part in the ultimate decision." The architect having washed his hands of the business, the other authorities proceeded to award the prizes, as follows:—Calder Marshall, R.A., £700; W. F. Woodington, £500; E. G. Papworth, £300; Giovanni Dupré, of Florence, £200; Mariano Folcini and Alisse Cambi, of the same city, £100; Alfred Stevens, £100; M. Noble, £100; E. J. Hähnel, of Dresden, £100; and T. Thorneycroft, £100. A

DESIGN FOR A LAMP STANDARD.
BY ALFRED STEVENS.

significant paragraph in their report was to the following effect:—"We have not considered ourselves bound to take into exclusive consideration the peculiar fitness and adaptation to that spot in St. Paul's Cathedral which appears to be in contemplation for the erection of the proposed monument; which consideration might possibly have led to some difference in the selection." They further suggested that on this point experienced artists should be consulted.

Lord John Manners then became First Commissioner of Works, and he announced in Parliament, in June, 1858, that he and Penrose had decided upon Stevens' design. On September 9th, 1858, they asked for a full-size model, and this was duly prepared.

Offering a few critical remarks upon the monument as carried out, Mr. Strange said he thought that the loss had been chiefly in the treatment of the upper portion, and in the figures. The upper storey seemed to have become rather heavy, when compared with the model, and the big projecting moulding would probably tend to obscure the equestrian statue when placed in position. Personally he would have liked to see the monument erected in the open air. The monument was originally in the Chapel of SS. Michael and George, which it was at one time proposed to make into a Wellington Chapel. Penrose was to be employed to make it suitable for this purpose, and a distinguished artist was to be commissioned to do the paintings, but nothing ever came of the proposal. Mr. Strange then quoted from contemporary criticisms of the monument. One of these read as follows:—

"Mr. Alfred Stevens's is one of the loftiest designs in the competition. An open arch rises upon a picturesque cluster of twelve isolated columns, supporting a rich pedestal, high above which stands the bronze statue of the Duke. Two groups of sculpture at the sides represent Truth crushing Fraud, and Valour quelling Cowardice; the two vanquished figures being flung out from the pile with a boldness and terrific spirit. Still, this monument is in the main architectural; it is in three stages—the first, an enriched base made up of twelve columns, which support an entablature bearing an enriched frieze, from which rises a semicircular-headed arch, the soffit of which is elaborately panelled. Over this arch the next stage is supported by four moulded columns; and from the ends of this stage are flung the strange figures we have referred to. Above this stage, on a plain entablature, but enriched pedestal, is an equestrian statue of the Great Duke. If, however, the monument is to be placed beneath one of the arches of St. Paul's Cathedral, this design—arch within arch—will be objectionable. The decoration of this monument is very elaborate; but we do not admire the selection or arrangement of the objects upon the sides of the sort of altar-tomb, upon which is placed the recumbent figure of Wellington."

Another criticism said:—
"The least worthy of the three, and indeed the least worthy of the nine, is that of Mr. Stevens. Built up in storeys of disjointed architectural members intended for quite other purposes, reminding one somewhat of the curiously and painfully raised fabrics sometimes seen on the floor of a nursery, with a formal altar-tomb inserted below, an equestrian figure at the top, and certain violently composed figures projecting midway from its sides, its uninteresting materials put together with scarcely so much design as to satisfy the requirements of constructive security, entirely destitute of dignity and repose, exciting no feeling in common with the character and associations of the Duke, it towers up so high an architectural pile as would completely block up the recipient archway, and would, if erected, constitute the heaviest, most inconsistent, and least suggestive structure that could well be conceived for such a purpose."

The "Critical and Descriptive Catalogue" of the Exhibition of the models contained the following:—

"'I know but of One Art.' A fine piece of Venetian architectural splendour, most admirable in its restrained richness, and well studied in its light and shade. Erected in a provincial square it would

THE WELLINGTON MEMORIAL IN ST. PAUL'S CATHEDRAL, WITH ALFRED STEVENS'S FULL-SIZE PLASTER MODEL IN POSITION.

DONATELLO'S "GATTAMELATA" AT PADUA.

be the pride and crown of the place. The bronze statue high in the air—the open arch below—the pillars—the crown—the crushed figure of War squeezed under his shield—are full of spontaneousness and originality."

Other criticisms from contemporary journals were as follows:—

"There are three other prizes of £100 each; and these have been given severally to No. 12, the work of two Florentines, MM. Mariano Folcini and Ulisse Cambi;

No. 18, that of Mr. Stevens; and No. 21, contributed by Herr Ernestus Julius Hähnel, of Dresden. Of these three, the award to the Englishman is unquestionably a mistake. On no possible principle of judgment can we understand how this work came to be singled out from such a collection as this—and least of all for such a purpose."

"No 18 is essentially architectural, and is carried to a great height. . . . Against the end of this [second] stage

are groups of figures that would puzzle a conjuror to make out what they are intended to represent; they may be Satan reproving Sin, or the Death of the Dragon of Wantley, or anything else you may choose to name. Reaching beyond these nondescripts, on a plain entablature, and to crown the whole, on an enriched pedestal, sits the Duke, on, we presume, Pegasus."

Continuing, Mr. Strange said that Stevens's model for the equestrian figure showed the Duke holding a cocked hat in his outstretched hand. There might be historical justification for this if the story he had heard was true, that Wellington had decided to hold out his cocked hat in his right hand as a prearranged signal for the advance at Waterloo.

Stevens must almost have thought with his fingers; they seemed to keep pace with the working of his great intellect. His restless mind was working ever through his eyes and hand, and was always striving to realise form. He had extraordinary perseverance in trying subjects over and over again in endless variety of arrangement.

Concluding, Mr. Strange said he would show one piece of Michelangelo's work, the tomb of Lorenzo de Medici, which had more in common with the finest work of Stevens than anything else of which he knew, and which, very strangely, hardly suggested any figure that Stevens ever drew. Stevens arrived at a pitch of ideality and abstraction which was not altogether inferior to that of Michelangelo. The Italian master worked under totally different conditions—amid a community of artists and art-lovers, at perhaps the most glorious period of Italian art. But Stevens was Early Victorian. If ever there was a voice crying in the wilderness, it was that of Alfred Stevens

GENERAL VIEW OF THE LARGE DRAWING-ROOM AT "DEYSBROOK," NEAR LIVERPOOL (NOW A CHILDREN'S HOSPITAL), SHOWING DECORATIONS BY ALFRED STEVENS.

DETAIL OF CEILING DECORATION IN LARGE DRAWING-ROOM, "DEYSBROOK,"
NEAR LIVERPOOL, BY ALFRED STEVENS.

the finished little work, and, like many other artists, was hopeless as a business man. But he lived life for his "One Art."

DISCUSSION.

Sir Charles Holroyd said he would most willingly propose a vote of thanks. Mr. Strange said that Michelangelo worked in a community of artists; he did, but nevertheless he was very solitary. When, for instance, he had finished part of the Sistine Chapel, and although the Pope was quite satisfied, Michelangelo said he was afraid that the times were unfavourable for art.

The door for the Geological Museum, continued Sir Charles, always struck him as better than that by Ghiberti, and the reason that he (Stevens) understood form better, and had kept the construction in a far finer way. Stevens might have received from the Sistine Chapel his inspiration for his beautiful designs, which included the forms of children linked together. The candlestick in the right transept of St. Mark's was probably that upon which Stevens used his design for a candlestick with winged figures around. Referring to the curious fact that casts seldom or never

realised the excellence of the first sketch, the speaker said that this was always the case, even with the finest workmen. Donatello's bronzes, for instance, were afterwards worked and chased with hammer and file. The seats in St. Paul's Cathedral, in the speaker's opinion, detracted from the effect of the Wellington Monument, and should be taken away.

Mr. D. S. MacColl, seconding the vote of thanks, said he was glad that the various studies and sketches by Stevens were shown to an enlarged scale upon the screen. Their effect was much better realised. Some of Mr. Strange's criticisms seemed extremely acute, but he was not disposed to agree with them all. Mr. Strange was of course a staunch upholder of Stevens's fame. Again, they had to thank Mr. Strange for the additional knowledge concerning Stevens's early life. The drawings which were thought to have been sent in for the competition at the Houses of Parliament were, said Mr. MacColl, now definitely known to have been for that competition. With regard to Deysbrook, Stevens did not make the drawings in a fortnight. He had the whole scheme planned out completely in his mind before starting for Deysbrook, and, arriving there, had rapidly produced

the decorations on the walls with the aid of two assistants.

In doing little things Stevens was rather too elaborate; but in big things all the exuberance fell away, and the subject came out in all its beautiful plain perfection. The friendly notice quoted by Mr. Strange bore the mark of one of the few men who really knew Stevens's worth, but who did not represent the general opinion. Recently Mr. James White-law, an architect who took the Silver Medal of the R.I.B.A., came back from Italy, and went to see the Wellington Monument in St. Paul's. He was so overwhelmed with Stevens's work that he made a complete set of drawings of the monument and presented them to the Stevens Society.

The story about the cocked hat was not legendary, but historical, and Stevens had it definitely in mind when he designed the monument. With regard to the monument, he was inclined to agree with some of its critics. The original design was perhaps finer; and of course it should be remembered that the first intention was for the monument to be carried out wholly in bronze, but marble was subsequently decided upon. The face of the marble arch, too, was to have been covered with bronze hangings.

Mr. W. Strange said that Stevens possessed one rare quality—he was a great draughtsman. Technically his drawings were masterly, easy, and certain, and were hardly excelled by any Italian draughtsman at any time.

Mr. W. R. Colton, referring to the great difference between models and finished productions, mentioned as an instance, the lions designed for the British Museum railings. The mane of the lion was literally gouged out in grooves, and he thought Stevens must have been bitterly disappointed. He would like to know whether the plaster model was in existence. He himself had a model which was infinitely finer than the finished work. In the door-knocker to Dorchester House they saw the same defect—the design was ruined by the reproduction.

Mr. Strange, in the course of a brief reply, said that Mr. Drury told him Dalou had criticised Stevens's work with great admiration, but said it always struck him that Stevens did sculpture like a painter. Stevens had two great friends at the time—Cockerell and Penrose—who secured him the commission for the Wellington Monument.

By the courtesy of Mr. Strange we are able to reproduce a number of the designs which accompanied his lecture. The original drawings are now on exhibition at the Victoria and Albert Museum, South Kensington. We are also indebted to Messrs. Henry E. Hoole and Co., Ltd., of Green Lane Works, Sheffield, by whose kindness we are able to reproduce a portrait of Stevens and some of his designs for firegrates. For nearly eight years—from 1850 to 1857—Stevens devoted a considerable portion of his time to designing and modeling grates, fenders, and similar work for Messrs. Hoole, who had the perspicacity to recognise the talent of a genius who, as frequently is the case, was not regarded at his true worth until after his death.

The bronze equestrian statue which is to complete the Wellington memorial is now finished, and it is hoped to have it fixed in position by St. Paul's Day, January 25th.

The monument was originally to have been surmounted by an equestrian statue, but this was opposed by Dean Milman.

This fine grate was made by Messrs. Hoole, of Sheffield, for the International Exhibition of 1862. The panel on the back represents "The Rape of Proserpina." The casing is relieved with vertical strips of ormolu at the angles.

The panels to this grate are shown in detail on the next page.

FIREGRATES EXECUTED FROM DESIGNS BY ALFRED STEVENS.

This grate and fender are executed in "armour bright" iron, the figures, serving as "dogs," being of cast bronze with ormolu enrichments at the bases.

FIREGRATES EXECUTED FROM DESIGNS BY ALFRED STEVENS.

These are Stevens's original cartoons for the blue and white porcelain panels to the grate shown on the preceding page.

Before his work was completed Stevens died. The statue which will crown Stevens's work has been designed by Mr. John Tweed from Stevens's unfinished sketch. The necessary funds are being collected privately by a committee, and the amount is almost in hand.

The exhibition of works by Alfred Stevens at the Tate Gallery, Millbank, which was to have closed on January 14th, will remain open until the latter part of March, the lenders having consented to extend the period of their loan in view of the great interest taken by the public in the exhibition.

MAGAZINES AND REVIEWS.

A considerable part of the "Art Journal" issue is devoted to an article by M. Salomon Reinach on "New Facts and Fancies about Leonardo da Vinci." "The Work of William Kent at Rousham" is, judging from the illustrations given, hardly worth an article; it is poor, commonplace stuff. The editorial article on the "Æsthetic Conditions of To-day," with its ill-natured and rather vulgar sneer at the Royal Academy, is neither very wise nor in very good taste. The "Art Journal" used to be on the side of rational and learned art; apparently now it is to uphold all the eccentricities of the day as representing the true art. This, to be sure, is to be in the fashion.

The "Burlington Magazine," in an editorial article, suggests, as a system of providing for the securing of national art-treasures for this country, that in the first place the annual grant to the National Gallery should be raised to £25,000, instead of the present absurdly inadequate £5,000, but that this increase should be voted as an annual increase to £10,000, and in addition to this a lump sum of £500,000 with interest at 3 per cent., which capital sum might be drawn upon, in case of necessity, for the purchase of any one of a certain selected list of masterpieces. "When this sum is used up the income of the National Gallery would have sunk to twice its present amount; but in expending the lump sum it is to be hoped that the greater part of the supremely important masterpieces of early art in the country would have been acquired, and the remaining £10,000 a year might well suffice for the building up of that much-needed collection of masterpieces of nineteenth-century art which is badly needed for the inspiration and guidance of artists in this country." It is not a bad idea. Something must at any rate be done to enable the National Gallery to purchase works which would otherwise be sold out of the country, or we shall gradually lose our most valued art-treasures. Is it any use hoping that some owners of great works might learn to be so patriotic as to refuse to sell them to the foreigner? That would be one way out of the difficulty. The new craze for Chinese art is illustrated in a long article on the contrast between a St. John the Evangelist by Titian and a picture of a Chinese saint, to the effect that the one is totally unreal and the other represents a Chinese saint as the painter saw him. This may be quite true, but it does not alter the fact that the one is a noble figure and the other a mean and ugly one; but that is apparently to be considered as of no consequence.

The "Architectural Record" (New York) is a very interesting number.

It contains an article on "The New San Francisco," with a number of illustrations of the new buildings, among which the typical high building of America seems less prominent than one might have expected, though the Humboldt Bank building takes the form of a high tower, not badly treated architecturally. The writer of the article, Mr. A. C. David, says that the old San Francisco was "a most winning and entertaining place, the least American of the larger cities of the United States," and that it contained a number of buildings of real architectural distinction, designed and built early in the 'fifties. The new San Francisco, judging from the illustrations given, will also contain some buildings of architectural distinction, though their quality is rather unequal. It is rather surprising to see that the complete classic columnar type of architecture is largely adopted for offices as well as for banks. The office of Messrs. Balfour, Guthrie and Co. is a square front with the windows between Doric columns. The buildings in which the columnar order is not used are not very refined in detail, but they are mostly what may be called sensible architecture, suited to the occasion. Following this is a very enthusiastic article on the Liverpool Cathedral, accompanied by a number of photographs, some of them showing the vaulting in progress, with the method of building the centering. We take it that the writer, Mr. Wilberforce Horsfield, is an Englishman; it would have been perhaps more interesting to have seen how the work strikes an American eye; but we think he is right in his conclusion that "Liverpool and Westminster Cathedrals are both well worthy to go down to posterity as examples of twentieth-century ecclesiastical art." Though the Liverpool Cathedral adopts the forms and details of mediæval architecture, it is no mere imitation; the plan and a great deal of the architectural treatment are quite new and original, and the interior of the Lady Chapel, the only finished portion, is a really fine piece of modern Gothic. The only thing we do not like in the illustrations is the reredos over the altar; the decorative cresting to this is far too exuberant. A piece of original architecture of quite another type is illustrated in an article on "The People's Savings Bank at Cedar Rapids, Iowa," by Mr. Louis Sullivan, an architect who evidently thinks for himself—perhaps a little too much; but the result in this case is certainly interesting. The fourth of a

series of articles by Mr. Sloan on the architectural treatment of concrete structures deals with "Concrete in Landscape Gardening." He shows that concrete can be very well used for small decorative fountain basins; the four illustrations of these are very good, and quite suitable for concrete; but in other illustrations the forms adopted are only imitations of masonry—a mistake constantly made in these cases. The grouped "columns for the Pergola," with their coarsely profiled cap and base mouldings, are very bad. To design characteristically in concrete, it is necessary to forget masonry forms altogether; which the designers obviously find it very difficult to do.

The "Nineteenth Century" contains an important article by Mr. D. S. MacColl on "The National Gallery; its Resources, Problems, and Administration." The problem, is, of course, how to secure the best pictures which are in the market, and prevent their being bought out of the country. He raises the question whether the expenditure of money by American millionaires in paying enormous prices for old pictures is a temporary craze or is likely to be a permanent condition; in the latter case, as he says, no mere raising of the annual grant to the National Gallery to £25,000 or even £50,000 will be of any practical use; the only thing is to fund a sum of a million to be drawn upon as necessity arises. Another point to be considered is to give greater power of independent action to the Director, so as to enable him to purchase at once, if necessary, without having to take the opinion of the Board of Trustees. That the trustees should be (as has been proposed) a committee of experts, he deprecates, and rightly; they would only differ among themselves and hamper the action of the Director. Another point which Mr. MacColl makes is that the reason the British Museum is so well served is that the head of each department has under him assistants who are also experts, going through a training which qualifies them to become heads of departments in their turn. He suggests that the same system should be established at the National Gallery, so that a new director may come to his post after a life of preliminary training for it.

The "National Review," which seldom touches on anything so frivolous as art, has an article by Mr. Austin Dobson on "Louthborough, R.A." whose well-composed but very artificial landscapes were at one time in considerable favour, and

THE PEOPLE'S SAVINGS BANK, CEDAR RAPIDS, IOWA.
LOUIS H. SULLIVAN, ARCHITECT.

may still be seen at dealers' exhibitions and loan exhibitions, but who also worked largely in London theatres as a scene-painter; as he had been intended for an engineer, he probably had acquired some technical knowledge which was of use to him in designing scenery. He was a Dutchman by birth, but at thirty settled in London and became practically an Englishman. As little is known of him, the article is of some interest, and a good deal of notice of contemporary events and people is worked into it.

In the "Contemporary Review" is a good article on Ruskin by Mr. Basil de Selincourt; an endeavour to state, in a sympathetic spirit, what was the real value of Ruskin's message to his generation, apart from the weaknesses of picturesque verbiage and wrathful exaggeration which, as the writer fully perceives, were Ruskin's weaknesses as a teacher, both in regard to art and life. It would take too much space to summarise his conclusions here, but the article is worth reading.

The "Century" gives a plan, illustrations, and a description of the Lincoln Memorial which it is proposed to erect at Washington, for which Congress has authorised an expenditure of two million dollars. The site recommended is an

admirable one, placing the memorial close to the Potomac river, on a site on the central axis of the Washington Memorial and the Capitol, which latter is at the opposite extremity of the vista. The proposed monument, of which Mr. Henry Bacon is the architect, takes the form of a kind of Greek Doric temple, with its longer axis at right angles to the main axis of the site; it is completely surmounted by a colonnade, and above the plane of the solid wall, within the colonnade, rises a blocking, rather Roman than Greek in style, with a frieze of garlands between each of which is the name of one of the States. The whole looks well enough, and is very refined in design, though it may be thought a pity that such a very American man as Lincoln should be commemorated in the architectural language, so to speak, of Greece and Rome. However, the classical idiom has been so fixed from the beginning on all the public architecture of Washington that perhaps it would be difficult to depart from it now without producing a discord.

"Scribner" contains an interesting article on "Abbey's last Mural Paintings," those made for the Pennsylvania State Capitol at Harrisburg. Some of them have been seen in London; one ("Penn's Treaty with the Indians") was exhibited a year or two back at the Royal Academy. The main and central picture is an "Apotheosis of Pennsylvania," containing portrait groups of the Pennsylvania worthies of past times. There are some interesting recollections as to the artist's life and his way of getting up materials for his large decorative works.

The "Antiquary" contains an article by Mr. Tavenor-Perry on "Hartlepool and the Church of St. Hilda," the commencement of an essay which is to be continued. A plan of the mediæval church is given; of the seventh-century church founded by St. Hilda there are no remains. Mr. D. MacRitchie (F.S.A.Scot.) contributes an article with a plan and section of a ruined earth-house on the South Uist (outer Hebrides); the centre compartment is circular and domed over, the domed portion (with horizontal joints) being carried on a series of arches supported on piers radiating from the centre with a narrow and lower passage round them. It is an interesting bit of prehistoric domestic architecture.

SOUTH LONDON TECHNICAL ART SCHOOL.

The annual report of the City and Guilds South London Technical Art School for the session 1910-11 shows that there has been a substantial increase in the entry of students during the year ending in July last, when the number on the register was 120, as against 103 in the previous session. The school, which is in the Kennington Road, can point to an extraordinary array of past students who have achieved high honour and distinction. Sir William Goscombe John, R.A., was, during the first decade of the school's existence, one of a group of students under Mr. W. S. Frith, in the modelling section, which included Sir George Frampton, R.A., Mr. F. W. Pomeroy, A.R.A., Mr. W. R. Colton, A.R.A., the late Mr. Harry Bates, A.R.A. Sir William Goscombe John studied at the school for three years previous to 1889, when he gained, like so many other students of the school, the gold medal and travelling studentship of £200 of the Royal Academy.

Of the House Decoration Section of the school, it is reported that last session's

work was of a most satisfactory character. Mr. W. K. Stevens, the teacher in this section, writes: "It is gratifying to find that there is more demand for really trained handicraft labour of all kinds, and in my opinion anyone thoroughly trained can find work at an ample remuneration."

NOTES FROM PARIS.

Contractors' Banquet.

In Paris, they know how to dine; and the annual banquet of public works contractors (Les Entrepreneurs de Travaux Publics) supported this proposition. It took place at the Hotel Continental, M. Augagneur, Minister of Public Works, presiding. The President of the Republic, and the Ministers of Commerce, of the Colonies, and of Works, sent representatives, many senators and deputies were present, and the band of the 102nd Regiment made the music. Such functions seem to afford a capital opportunity of getting influential men by the ear, and M. Chagnaud, president of the contractors' syndicate, seems to have done justice to the occasion. He pointed out that in Paris a great deal of work that ought to be done was being neglected—in one quarter, for instance, the unfulfilled promise to lay down tramways was twenty years old. Also he demanded from the Government such action as would ensure the contractor entire freedom from molestation in his business. He demanded that all attempts at violence and sabotage should be put down with a firm hand. The reply by the Minister of Works need hardly be chronicled. It took the usual stereotyped form. He took a very sympathetic view of the need for further expenditure on public works, but regretted that the exigencies of the budget. . . . The formula is only too familiar. Also he condemned very indignantly the destruction of property by workmen, and even ventured on the quite definite pronouncement that "Le sabotage est odieux"! but he did not say what would be done to put a stop to it. Nevertheless, it was a great occasion. Cannot our British Institute of Builders, or Federation of Employers, persuade a few Cabinet Ministers and high public officials to "assist" at the annual banquets?

House of Retreat for Architects.

M. Lucien Leblanc, architect, of Paris, has conceived the idea of creating a house of retreat for architects, and is going to submit a scheme to the Central Society of Architects. Until the particulars are made public, the fancy plays round all sorts of wild possibilities—homes of rest, convalescent homes, almshouses, and what not. Whatever form for the *maison de retraite* may be suggested, its bare conception seems to indicate that the French are either a less proud or a more practical people than we are. In any case, developments will be awaited with interest; for it may quite possibly turn out that M. Leblanc's scheme is worth imitating.

The Prix de Rome.

The dates of the 1912 competition for the Prix de Rome have now been fixed: First sitting (12 hours' sketch), March 12. Second sitting (24 hours' sketch), March 15th. In each case the sketches will be judged on the following day. The *Loge* day is March 19th; and the exhibition for the final competition will be held on July 23rd, 24th, 25th, and

DETAIL OF COLUMN IN THE PEOPLE'S
SAVINGS BANK, CEDAR RAPIDS, IOWA.
LOUIS H. SULLIVAN, ARCHITECT.

27th; judgment being delivered on July 26th. The Prix de Rome, it may be recalled, was founded in 1720, and entitles the winner to a stay of three years in Rome at the expense of Government, with the certainty of a position as Government architect. The competition is open to all Frenchmen between the ages of fifteen and thirty, whether or not they are members of the Ecole des Beaux-Arts. The awards are given by a jury consisting of the eight architect members of the Institut, twelve other permanent members, and nine who are renewed from year to year.

The Gare de Grenelle.

The Paris Municipal Council has approved of the scheme for reconstructing the passenger portion of the Gare de Grenelle; towards the cost of which the city will pay a contribution of 35,000 francs to the railway syndicate of the Ceinture.

A Palace of Agriculture.

The Parliamentary Commission entrusted with the duty of enquiring into the project for building, in Paris, a Palace of Agriculture, has concluded its labours, and presented its report to the Government. Two projects have been put forward by the Commission. The first proposes the use of the site of the Halle aux Vins; the second, the building of the palais at the Champ de Mars. A third site is proposed by a minority of the commission, who suggest building on lands at the rear of the Ecole Militaire.

Palace of Justice, Constantine.

The awards in the competition for a palais de justice at Constantine, Algeria, have been announced. M. Dumoulin, of Algiers, is placed first, and will superintend the work. The project placed second is that of M. Richard, of Paris, who receives 3,000 francs; while the third premium, 1,500 francs, goes to M. Christofle, of Constantine.

A Fresco Class.

A course of instruction in fresco painting has been instituted at the Ecole des Beaux-Arts, with M. Paul Baudoin as instructor.

Society of French Artists.

The Société des Artistes Français has elected the following "bureau" for 1912: M. V. Laloux, architect, member of the Institut, president; M. Boisseau, vice-president; M. Dawant, vice-president; M. Louis Bonnier, secretary-reporter; M. Focillon, secretary-treasurer; MM. E. Renard, Georges Lemaire, Pascal (member of the Institut), and Jules Jacquet, secretaries.

A New Director of Works.

The new administrative director of works for Paris is M. Cacaud, prefect of the Ardennes. He succeeds M. de Pontich, who has been appointed receveur municipal of the City of Paris.

Garden City Exhibition.

An exhibition of the designs premiated in the competition organised by the Comité Départemental des Habitations à bon Marché de la Seine has been held in Paris, which has thus achieved its first Garden City Exhibition. The designs were on view for a week in the Salle Saint Jean of the Hotel de Ville, and no charge was made for admission, the object being to popularise the garden city idea. The first French garden city will probably be built in the department of the Seine.

Huge New Stores Projected.

Paris, already rich in large business buildings, is about to make two important additions to them. The two opposite corners of the Rue Royale, at the Made-

COTTAGES ON FARNHAM ROAD, GUILDFORD. DRAWN BY HAROLD FALKNER.

leine, have been respectively acquired by two rival syndicates, who are going to erect huge dry-goods stores, as they would be called in America. It is stated that the capital to be expended on these undertakings will amount, in the aggregate, to not less than two millions sterling, a considerable portion of which will necessarily be expended on the buildings, the architectural treatment of which will be regarded with considerable interest, as they should represent the *dernier cri*.

CORRESPONDENCE.

Cottages, Farnham Road, Guildford.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Of the cottages you illustrated in last week's issue, I send herewith an old drawing I made years ago while waiting for a train at Guildford. They are a delightful group, looking either up or down the road, and I am prepared to answer your question that they are perfectly sanitary and dry, as they stand up some 3 ft. above the pavement, and had, when I saw them, been recently redrained.

I do not think any words of mine can add to the splendid letter of the Master of Charterhouse to the "Times," or your leader thereon, but I can say that I know the road and the way in and out of Guild-

ford very well, and that this is *not* the place where the road wants improving.

There is a speed limit of 10 here, and at that pace the spot is not dangerous.

What is required is that the corner from the railway bridge should be taken off so as to let motor-traffic from Farnham into the North Street and a new road from the top of North Street into the London Road so as to avoid the High Street and Spital Street altogether.

Speaking of the cottages, the public would appreciate them more if the timber work which undoubtedly exists under the rough-cast showed. The main street is capable of respecting the old, and recognises timber houses as old. He is of course incapable of appreciating the beautiful, because he doesn't see it.

I do not for one moment counsel the removal of the rough-cast. As a matter of fact it simplifies the buildings and throws up their extraordinarily successful grouping. The importance of these cottages is as an auxiliary to the other most important buildings—Bull's, the Capital and County, the County Court, Town Hall Chambers. They help one to realise what an old town was like. They give strangers coming from the station just the impression they should have, that there is something good in Guildford, and that it may be, as it is, worth while to go on beyond.

H. FALKNER.

TRADE AND CRAFT.

Artistic Lighting Fittings.

It is not very often that a trade catalogue can be truthfully described as being really delightful. From Mr. W. J. Stokvis, of Arnhem, Holland, we have received a catalogue of lighting fittings, seventeenth-century replicas, in which these illustrations are beyond question artistically charming. Mr. Stokvis, whose business was founded some five-and-forty years ago, has gone to the museums and art galleries for his models, has selected these with true taste, and has copied them with the utmost fidelity, reproducing not merely the beautiful form of the original, but its spirit also. Gerard Terborgh, Frans von Mieris, Gerard Dou, Gabriel Metsu, Quentin Matsys, Nicolaes Maes, A. van der Werff, Jusepe de Ribera, David Teniers, and many another Dutch or Flemish artist, have been laid under contribution, the artists named being represented in the catalogue by reproductions of some of their pictures in which appear ceiling lights, lamps, or lanterns, of which copies have been made in three dimensions; and in each case the picture is shown in juxtaposition with an illustration of the object of which it has inspired the making. Mr. Stokvis, however, has gone farther afield than the Low Countries. Great Britain, Germany, Italy, and Spain have yielded him some choice examples of early design and craftsmanship in metal-work, with the result that his catalogue shows a fine range of choice, both in the object and in its treatment. With respect to each object figured—electrolier, lantern, candlestick, or what not—the source of the original is indicated, so that the authenticity of the design may be easily verified. The numerous candelabra are strikingly beautiful; and the quaint old-world charm of the beautifully proportioned lanterns or hanging lights, such, for example, as those taken from Gerard Dou's "Girl with the Burning Light," from Teniers's "Guardroom," and from Ribera's "Diogenes with the Lantern," is simply irresistible. The articles are made either in polished or oxidised brass, and are adapted for ordinary gas, acetylene, or electric light. Mr. Stokvis's beautiful work secured a gold medal at the Brussels Exhibition of 1910, and the Grand Prix at the Roubaix Exhibition of 1911. His English agent is Mr. E. C. Sparkes, 118 and 120, Wardour Street, London, W.C.

Vitreous Tiles and Mosaic.

Wall decoration, whether the building to be treated be public or private, offers many æsthetic opportunities, of which the architect is not slow to avail himself. The materials at command are so many and varied as to create some embarrassment in the choice. In considering the problem, it should be taken into account that while an artistic glass tiling may entail a greater initial expenditure than some other methods of finish, there is no doubt that its advantages are considerable. The vitreous tiles and mosaic manufactured by Messrs. Chance Brothers and Co., Ltd., of the Glass Works, near Birmingham, are of much interest because of their durability, entirely sanitary surfaces, brilliant tones, and the variety of colour marking that may be obtained, as well as their freedom from all possibility of crazing. The tiles are produced with regular edges for work requiring a tight

joint, and also with antique rough-cut edges; while moulded angles, cappings, and skirtings are produced, so that a complete scheme can be carried out in the material. For entrance halls, vestibules, staircases, bathrooms, fireplace surrounds, and similar work, they give an excellent effect; and when this material is used as mosaic, floors of indestructible character can be obtained. We are informed that samples may be had at any time on application to the manufacturers.

Standardisation of Shop-Fronts.

A remarkable development in shop-front fitting is announced. Messrs. E. Pollard and Co., the shopfitters, of Clerkenwell Road, London, E.C., have elaborated a system of standardising metal shop-front work, so that the parts are interchangeable and can be put together without difficulty by builders who are not specialists in shopfitting, and of which the price per foot run is a known factor. As Mr. E. Pollard points out, however, the standardisation of shop fronts, pricing them at so much per foot run, and supplying them complete for local fitting, are the bare outlines of the idea. The standardisation of parts effects enormous economies, because it gets rid of the heavy cost of preparing special dies and tools; whereas the standardised shop-fronts can be produced at the cost of metal and labour only. "We have an extensive plant of metal-drawing machinery," Mr. Pollard explains, "and by standardising our work, and arranging our metal workshops on scientific lines, we have cut down the cost of metal shopfronts until they are within the reach of the smallest shopkeeper in the smallest town." The most practical and successful patterns and sections have been selected for standardisation. Several styles are available, and much variety may be imparted by the use of bent returns, "island" windows, and other devices. The builder who is interested in the erection of shop property will no doubt be glad to avail himself of the advantages which Messrs. Pollard's system affords, of putting in elegant and attractive modern metal shop-fronts of which the cost can be so easily calculated beforehand, which bring business to the shop-keeper, and secure tenants for speculatively built shop property. The metal used may be brass, bronzed metal, gunmetal, or German silver; and Messrs. Pollard will be pleased to suggest plans and schemes, and to estimate costs, on receipt of measurements of frontage and an indication of the depth of lobby required.

LOCKWOOD'S PRICE BOOK.

The term "Price Book," which is a survival from early days, when its significance was not exceeded, has long ceased to cover adequately the variety of subjects included in a volume which has greatly outgrown its title. The prices no doubt remain a very important feature, but are perhaps less valuable in themselves than in the opportunity they afford of enumerating the resources that are at the disposal of the architect and the builder in the matter of materials, manufactures, and methods, the systematic entries under each trade marshalling for convenient review the innumerable units which collectively represent the forces at command; and these occupy about two-thirds of the volume. The remainder of the book is very usefully filled with tables and memoranda, the R.I.B.A.

building contract, legal notes, marks and qualities of wood, the texts of various building and public health acts and by-laws, and other matters of use and interest, which render it invaluable as a work of reference for architect and builder.

Lockwood's Builders', Architects', Contractors', and Engineers' Price Book for 1912. Edited by Francis T. W. Miller, A.R.I.B.A. With supplements containing the London Building Acts, 1894 to 1908, etc., etc. London: Crosby Lockwood and Son, 7, Stationers' Hall Court, Ludgate Hill, E.C. Pages clxvii.+488+vi.+260, 6½ins. by 4½ins.; price 4s.

OFFICERS' TRAINING QUARTERS.

The new Headquarters, Officers' Training Corps, Glasgow University Contingent, officially opened on January 12th by the Right. Hon. the Earl of Rosebery and Midlothian, Chancellor of the University, is built upon a portion of the playing-field, and fronts upon the building-line of University Avenue, adjoining the gymnasium buildings. The drill-hall is about 70 ft. by 43 ft., and a miniature range of 25 yds. is erected alongside, and equipped with the "Solano" target. The front building is of 2 storeys, and is faced with white stone. The ground floor comprises adjutant's room, infantry and engineers' orderly rooms, engineers' store, armoury, and also cloak-rooms and lavatory accommodation. On the upper floor are the officers' mess room, lecture room, and library, cadets' dressing-room, and large infantry store.

The plans were prepared by Messrs. H. and D. Barclay, architects, and carried out under Mr. Colin Sinclair, M.A. Professor Medley took an active interest in the inception and carrying out of the scheme, and was assisted by Captain A. N. E. Browne, adjutant, and the officers of the corps.

The contractors for the work were: Messrs. Robert Murdoch and Son, mason work; Messrs. Ferguson and Anderson, joiner work; Messrs. Peter White and Co., slater work; Mr. John McFeat, jun., plumber work; Messrs. William Tonner and Sons, plaster work; Messrs. D. Campbell and Son, painter work; Messrs. Ashwell and Nisbet, heating engineers, and Messrs. Brownlie and Murray, steel roofs. Mr. John Stitt, Master of Works to the University, superintended the erection of the building.

LONDON FIRES IN 1911.

The official statistics of London fire during 1911 show that during the twelve months there were 4,455 fires, an increase of 1,250 compared with the previous year, and the largest number known to the London Fire Brigade. During the exceptional summer the Brigade dealt with 50, 60, and even 70 fires a day, many of them on the commons and open spaces around London—an explanation that in a large measure accounts for an increase that might otherwise be regarded as alarming.

One hundred and twenty persons lost their lives at London fires during the year. Over 100 persons were rescued by the firemen from burning buildings. The fires included that in Sidney Street on January 3rd, when a superintendent received injuries which resulted in his death; that at the Carlton Hotel on August 9th, which resulted in the loss of one life; and that at Messrs. Bowater's paper warehouse, Seawitch Wharf, East Greenwich, on September 11th, which burnt for nearly a fortnight, and which caused damage estimated at £40,000.

OF WELLINGTON FOR THE MEMORIAL IN ST. PAUL'S CATHEDRAL, LONDON.

PROPOSED NEW PARLIAMENT BUILDINGS, WELLINGTON, NEW ZEALAND: DESIGN AWARDED THE FIRST PREMIUM (£1,000).
J. CAMPBELL, F.R.I.B.A., F.N.Z.I.A., AND C. PATON, ARCHITECTS.

NEW PARLIAMENT BUILDINGS, WELLINGTON, N.Z.

Colonel W. L. Vernon, F.R.I.B.A., Government Architect of New South Wales, and the assessor in this competition, has made the following awards: First prize (£1,000), John Campbell and Claude Paton, Wellington; 2 (£500), Thomas Turnbull and Son, and J. S. Seddon, Wellington; 3 (£300), W. H. Gummer, Auckland; 4 (£200), John Campoell and C. A. Lawrence, Wellington. There were thirty-three competitors, and, in all, 327 drawings. A remark that would hold good for almost all important competitions is as follows: "The work of adjudication is not made easier by the apparent indifference of some authors to the important question of cost; whose designs for this reason necessarily lose ground." In the conditions it was stated that the cost was not to exceed £110,000. The drawings were to be executed only in pen and ink, without colour of any kind, excepting that a wash of colour might be applied on the plans and sections over the area of those portions of the building that are to be erected at a later date; while the elevations only might have shadows of a light monotone cast at an angle of forty-five degrees with horizontal and vertical planes to indicate projecting parts; and the door and window openings and roofs might have a flat pale wash of ink or of the monotone; but the walls on plans and sections were to be filled in with black indian ink only. Each competitor was required to furnish a typewritten report describing the building and stating the exact cubical contents with the estimated price per cubic foot, to include heating, ventilation, electric light, "and other works, structural as well as mechanical, necessary to fit the building for the reception of furniture, and the efficient fulfilment of its purpose." The efficient lighting, heating, and ventilation of the interior of every part of the building were to be considered as of primary importance. The building was to be designed "so as to afford reasonable resistance to fire and earthquake shocks, and provision must be made for the use of materials best adapted for these conditions."

The first three premiated designs are shown on this and succeeding pages.

THE ULSTER SOCIETY OF ARCHITECTS.

The above society held its annual general meeting on Monday, January 8th. There was a good attendance of members and associates.

Routine business being disposed of, the report of the Council for the year 1911 was submitted, discussed, and adopted, as follows:—"During the year 1911 the Council held six meetings, which were well attended. In addition three general meetings were held, to which all the members, associates, and students were invited. We regret that these general meetings were not better attended, and the Council hope that in future the members and associates will give practical support to the Society by taking an active part in the discussions and business arranged for the general meetings."

"During the year we received three resignations. It is therefore strongly urged on our junior members that those associates who are qualified for full membership should seek to be enrolled as

members, and take their proper place and standing in the ranks of the profession.

"At no time in the history of our Society has there been greater need, in the interest of the junior members, for co-operation and combined effort, with a view to improving the conditions of architectural practice, particularly in the interests of the younger members of the profession. Every week brings reports of the actions of the numerous district and urban councils who are carrying out, or proposing to carry out, small building schemes for labourers' and workmen's dwellings, and larger schemes for technical and municipal buildings and schools. In the great majority of cases the architectural work in connection with these schemes is entrusted to road surveyors, builders' clerks, and country surveyors' assistants, or others. The Board of Works and other controlling Government bodies have sanctioned and approved of such persons being employed as architects, thus frustrating the purposes and intentions of those who originally framed the provisions of the Labourers' Act. The

PROPOSED NEW PARLIAMENT BUILDINGS, WELLINGTON, NEW ZEALAND.
PRINCIPAL FLOOR PLAN OF FIRST-PREMIATED DESIGN.

results of such policy on the part of the local Government Board are to be read in the reports of badly designed and badly built houses, necessitating an excessive annual outlay in repairs or reconstructions.

"With such warnings in view, we find that during this year several rural and urban district councils have rescinded previous resolutions and have appointed architects assistant county surveyors, who had already accepted office on condition that their full time should be devoted to their duties as surveyors. Such appointments are remunerated at rates that would be a positive loss to any unqualified person who would faithfully and conscientiously carry out the duty attached to these appointments.

"During this year the Belfast Corporation Bill has passed Parliament, and will in due course result in a revision of the existing by-laws in force in this city. Such by-laws will be likely to affect architectural practice and the interests of building owners. It is of extreme importance, not only to architects, but also to building owners, that competent consideration should be devoted to the framing of such by-laws, which will have far-reaching results, either for good or evil, in the future progress, both architectural and commercial, of our city. We have been assured that your Society will have the opportunity of considering the draft by-laws before the same are presented to the City Council for final adoption.

"The interests of the members will be safeguarded as far as possible by your Council, but it is earnestly requested that every member of the Society will loyally co-operate with and support the Council in every possible way.

"The matter of affiliation with the I.B.A. has been further pressed, and it is hoped that within a reasonable time this will be accomplished."

The Hon. Treasurer, Mr. Houston, submitted a statement of accounts for the year, which showed the Society to be in a satisfactory financial position.

A discussion arose as to the best means of furthering the objects of the Society, and some recommendations were made to that effect to the incoming Council.

Reference was made to municipal undertakings, as the proposed Art Gallery, and the proposed competition for workmen's dwellings.

Mr. McDonnell referred to the candidature of Mr. Gilliland for membership of the City Council, and proposed "That the Society learns with pleasure of the candidature of W. J. Gilliland, F.R.I.B.A., for Victoria Ward, knowing, as it does, the attention and expert knowledge he will bring to further all the interests of the city in the large expenditure about to be entered into in municipal undertakings, and the Society trusts that Mr. Gilliland will be successful in his candidature." The motion was passed with acclamation.

Ballot papers for officers for the coming year were then opened by the scrutineers, resulting in the election of officers as follows:—President, H. Seaver, B.E.; Vice-President, J. J. McDonnell, J.P.; Council, W. J. Gilliland, F.R.I.B.A., F. M. Young, F.R.I.B.A., and N. Fitzsimons, F.R.I.B.A. Associate Members of Council, T. W. Henry and J. Seeds. Auditors, F. H. Tulloch and James Ferguson; Hon. Treasurer, E. R. Kennedy, F.R.I.B.A.; Hon. Secretary, Thomas Houston, Kingscourt, Wellington Place. The Corresponding Committee of Derry Architects to elect two members of Council in addition to above.

A SUB-CONTRACTOR'S CLAIM.

A case of interest to builders came before His Honour Judge Bonsey at the South Shields County Court on Thursday of last week. Mr. Thomas Anderson of that town, master plasterer, sued Messrs F. H. Heath, Ltd., of Manchester, contractors and builders, for £52 18s. 1d., in respect of extra work on a contract which he had with the latter to plaster the new Empire Theatre at Chester-le-Street.

Mr. Anderson was represented by Mr. W. H. Hope (of Messrs. Ritson and Hope, Sunderland), and Messrs. Heath were represented by Mr. E. J. Meynell, barrister-at-law, instructed by Messrs. J. Hislop and Son, of Manchester.

Mr. Hope stated that there was a contract to plaster out the auditorium from dado height, and to cover with fibrous plaster the roof principals, and to supply a fibrous plaster proscenium for the sum of £114 2s. The work was described

by the architect, from whom the plasterer got the details on which he based his price, and to which he made his fibrous work. Owing to a variation in the radius of the arch of the principals from the sketch supplied to the plasterer, the fibrous work would not fit, and key blocks were inserted at the joining of the sections of the moulded cornice, and further plastering was necessitated, and was done with the concurrence of Messrs. Heath's foremen on the job. As the dado should have been carried out in pressed brick, and was built in common brick, it was agreed that the dado would be rendered in cement. Rooms which should have been cleaded were got ready for plastering, and Anderson's men, on being told by Heath's men on the job that the rooms were ready, plastered them out without further orders. There was also a claim for overtime worked at defendants' request.

Mr. Hope contended that Messrs. Heath had constituted the architect their agent,

THOMAS TURNBULL AND ISON, F.R.I.B.A., F.N.Z.I.A., AND J. S. SEDDON, ARCHITECTS

PROPOSED NEW PARLIAMENT BUILDINGS, WELLINGTON, N.Z. DESIGN AWARDED THE THIRD PREMIUM (£300).
WILLIAM H. GUMMER, ARCHITECT.

and that Messrs. Heath's representatives on the job were competent to agree to the extra work due to defendants' deviation from the plan, though defendants contended that plaintiff should have taken his measurements from the building itself. The account had never been disputed, but had been embodied in the builders' account and rendered to the architects by the defendants, with directions to the architect to pay it. The architect had agreed to payment for the work which he had considered was not in the builders' contract, providing also for the builders' profit, but had refused to pay the items of extra work, on the ground that he considered that the work was necessary to be done before Heaths could be said to have carried out their principal contract, and they had been paid all that was due on that contract.

Mr. Meynell contended that the defendants never ordered the work, and that their representatives on the job had no authority to place any such orders or to confirm the architect's action in any respect, and that the architect was the agent of the building owners, and that if he had pledged anyone to payment for the work, it was the building owners. He contended that the price for the extra work to the principals was excessive, and disputed the order for overtime to be worked.

After a lengthy hearing, His Honour, in summing up, said Mr. Meynell contended that plaintiff could not recover because he could not produce an order in writing given by Mr. Heath himself, the managing director of the defendant company. As a general principle, that contention was right; but a foreman under certain circumstances has some authority, and he may consent in the interests of his master to slight deviations or substitution, and even order goods of a small nature. It might be that if the case depended on that the judge would not be inclined to find for the plaintiff at all. It would be too doubtful and too dangerous to admit such authority of the foreman; though in this case there would be no objection to a foreman ordering work, having regard to the fact that, in the defendants' interests, great pressure was being put on plaintiff to hurry with the work. "Owing to the principals living such a distance from the job there could be no objection to the foreman giving small orders. The architect in the contract was not the agent of the building owners. He was Heath's agent. Heath says he relied on the architect to see the work carried out properly. The architect thinks the work properly done as extra work, and Anderson ought to be paid for

it by Heath, who may or not be in a position to recover from the theatre company. . . . I must say that there is very strong evidence of the complete ratification of the acts of the foreman and architect. . . . But as to the price I shall make the deduction of £5 from the £19 charged. As to the other items, which are smaller, and depend upon the foreman (with the exception of the dado) they are disposed of as Heath's orders." The judge disallowed the last two items of £3 10s. 6d. and £1 5s. 1d., the deductions making, in all £9 15s. 7d., and gave judgment for £42 19s. 6d. with costs.

THE GARDEN CITY MOVEMENT.

The Garden Cities and Town-Planning Association, in order to cope with their increasing work, have taken larger premises at 3, Gray's Inn Place, W.C. The premises are upon the ground floor, and provision exists for the holding of classes and meetings. A programme of classes has been arranged in order to give practical instruction in "What Town Planning Means," and in order to equip a number of lecturers for popularising the movement. It is proposed to deal with the legal, sociological, architectural, engineering, municipal, financial, and scientific aspects of the question, while the point of view of the private owner of land will be specially dealt with. Particulars of the classes may be obtained from the Secretary. The annual meetings of the asso-

ciation will be held at Carpenters' Hall, London Wall, E.C., on Monday, February 5th, when the Hon. Mr. Justice Nevill will be in the chair; Mr. Cecil Harcourt, M.P., will speak on the progress of the movement, and Professor S. I. Adshead, F.R.I.B.A., will give an address on the beautifying of London.

Letchworth Garden City's Financial Success.

The Letchworth Garden City, which has been in existence for eight years, shows, by its latest report, a net profit of £174 14s. The growth of the town is shown by the fact that last November there were 1,515 houses, shops, and buildings, and, in addition, 49 factories and workshops. Those, with the addition of 115 houses, schools, etc., on the estate when purchased, made a total of 1,630 permanent buildings. Apart from the introduction of new industries, the enlargement of existing factories has become an important element in the growth of the town. The health of the town is excellent, and the death-rate is believed to be the lowest in England; it is stated to be 6.3, against 13.4 for the whole country. The infantile mortality rate is 54.54, compared with 106 for the whole country. Although it will not be possible to declare a dividend for two or three years, the directors hold the opinion that the Garden City idea has definitely proved itself economically and financially sound. This experience is very gratifying, not merely with regard to Letchworth, but as an augury for the general movement.

PROPOSED NEW PARLIAMENT BUILDINGS, WELLINGTON, N.Z. PRINCIPAL FLOOR PLAN OF THIRD-PREMIATED DESIGN.

NEWS ITEMS.

A Town Plan for Portsmouth.

At last week's meeting of the special town-planning committee of the Portsmouth Corporation the borough engineer was instructed to prepare a preliminary "town plan." It is understood, however, that the scheme at this stage will not go beyond the outlining of roads, etc., and be marking out of sites for public buildings.

Stevens's Wellington Monument.

Mr. John Tweed's bronze equestrian statue of the Duke of Wellington, which has been remodelled from the original design by Alfred Stevens, was placed in position at the summit of the Wellington Monument in St. Paul's Cathedral on Thursday last, January 18th, and is to be unveiled on January 25th, the date of the Feast of the Conversion of St. Paul.

Change of Address.

Messrs. Pepler and Allen (Mr. George L. Pepler, F.S.I., and Mr. Ernest G. Allen, A.R.I.B.A.), architects, surveyors, consulting land agents and valuers, announce that they have moved to Howard House, Arundel Street, Strand, W.C. The telephone number (Central 637) and telegraphic address (Rusinurbe, London) will not be changed.

Books on Architecture and Building Construction.

Messrs. W. and G. Foyle, of 135, Charing Cross Road, W.C., send us their latest catalogue of technical and scientific books. The list is a very comprehensive one, and includes a large number of books on architecture, building construction, and kindred subjects. The prices quoted are for new copies and the latest editions, but nearly all the books can be obtained second-hand at about half the published price.

Winnipeg Legislative Building Competition.

Mr. Ian MacAlister, Secretary of the R.I.B.A., informs us, in a letter dated January 18th, that he had then just received from the Minister of Public Works, Manitoba, the following cablegram in reference to the above competition: "Date for acceptance of plans extended to March 31st." Notification to similar effect has also been sent to us by the High Commissioner for Canada.

Proposed New Bridge at Twickenham.

The subject of a new bridge over the Thames at Twickenham has occupied the attention of a committee of the Twickenham District Council for some months, and a short time ago the council received the committee's recommendation to concur in the opinion that a footbridge should be constructed, and that the Surrey and Middlesex County Councils, the Ham District Council, the Dysart Trustees, and the owners of land on Eel Pie Island should be approached with a view to their contributing towards the expense of construction, estimated at £6,000. The recommendation was referred to the Town Planning Committee of the council.

Magdalen College Tower to be Restored.
After the Tom Tower, Oxford, it is the plan of Magdalen Tower to submit to the

restorer. Twenty years ago a good deal of work was done in restoring the carving and tracery, but further restoration is now necessary, and in the course of this year the work will be undertaken.

Rochdale Infirmary Extension.

The awards in this competition are as follows: 1st, Mr. Hugh Healey, A.R.I.B.A. (Jesse Horsfall and Healey); 2nd, Messrs. Sykes and Evans; 3rd, Messrs. Butterworth and Duncan—all of Rochdale, the competition being limited to local architects. The premiums were 50, 30, and 20 guineas respectively. Eleven designs were submitted.

Halifax Town-Planning Competition.

Professor Adshead has made the following awards in this competition: 1st, Messrs. Longbottom and Culpan; 2nd, Messrs. Medley Hall and Son; 3rd, Messrs. C. F. L. Horsfall and Son—all of Halifax, the competition being a local one. The premiums were 100, 30, and 20 guineas respectively. Eight designs submitted, which will be exhibited shortly at the Town Hall, Halifax.

Caerleon College.

A new training college for teachers is to be erected at Caerleon, near Newport, Mon., from designs by Messrs. Alfred Swash, F.R.I.B.A., and Son, architects, of Newport. The contract has been secured by Mr. F. Bond, of Cardiff, at £26,000, exclusive of the cost of site, furniture, and fittings. The college will be for the training of male teachers, the female teachers going to the new establishment at Barry.

The Villa d'Este as an Academy of Art.

The announcement of the "Tribuna" that the Archduke Francis Ferdinand has presented the Villa d'Este at Tivoli to the Austrian State in order that it may be transformed into an Austrian Academy of Art, similar to the French Academy in the Villa Medici on the Pincio, is not, the Vienna correspondent of the "Times" reports, expressly confirmed, but is probable. It is no secret that the Archduke Francis Ferdinand, who inherited the Villa d'Este as the heir of the last Duke of Modena, regards it as a white elephant, of which the upkeep is estimated to cost as much as £4,000 a year. The question of selling the villa has repeatedly been discussed, but a sale is said to have been discountenanced in the highest quarters.

Carpenters' Company's Prizes.

The Worshipful Company of Carpenters offer prizes to "Craftsmen, or those engaged in the actual work or carpentry, joinery, or the other arts connected with building," who must have attended at least five lectures of the series on the arts connected with building that are now being delivered at Carpenters' Hall, for the following designs:—(1) Row of six labourers' cottages, cost not to exceed £1,000; (2) Village workmen's institute, cost not to exceed £350; (3) design for any piece of domestic furniture in any material. For (1) and (2), the prizes are £5 5s. and £2 2s.; for (3) £3 3s. and £1 1s. The first lecture of the series is to be delivered to-night, at 7.45 p.m., by Mr. Thackeray Turner, F.S.A., whose subject is "The Unity and Difference in Art and Craft."

NATIONAL FEDERATION OF BUILDING
TRADES EMPLOYERS.*Midland Centre Annual Meeting.*

The annual meeting of members of the Midland Centre of the National Federation of Building Trades Employers was held at the Imperial Hotel, Birmingham, on Thursday, 11th January. The President (Councillor J. Hardy Walker, of Derby) was in the chair, and there were 35 members present. The following officers were appointed for this year: President, Mr. J. B. Whitehouse (Birmingham); vice-presidents, Messrs. W. Yates (Leicester) and G. Gough (Wolverhampton); treasurer, Mr. H. Willcock (Wolverhampton); auditors, Messrs. R. Webb (Birmingham) and A. Brazier (Bromsgrove.) Representatives to the National Council, National and Midland Conciliation Boards, etc., were also appointed.

The annual report stated that during the past year the labour unrest necessitated somewhat frequent meetings of the various Conciliation Boards. Perhaps the most serious difficulty during the year was with the Builders' Labourers at Nottingham, who were on strike for two months in the early summer, and were sympathetically supported by other branches of the trade. Five meetings of the Midland Centre Conciliation Board were held, with results that have been already recorded.

The membership of most of the affiliated Associations was well maintained, Birmingham reporting an increase of 26, and Nottingham of 10. The first Midland Centre Year Book and Directory was issued in March last, and the committee had been much encouraged by the appreciative reception accorded to it. A scheme for the insurance of members against Workmen's Compensation risks had been adopted. The most important matter, perhaps, that had been before the Federation during the year was the National Insurance Bill. Whilst generally approving the principle of a National scheme of insurance, the members came to the conclusion that the measure before Parliament required careful consideration, and the efforts of the National Federation, the Centre, and the local associations, were consequently directed towards securing amendments and urging the necessity for delay before the Bill became law.

[Although the desired delay has not been granted, efforts to get the Act amended will doubtless not be relaxed, and its effects on the building industry should be carefully watched and recorded.]

The report was approved and adopted. It was decided to hold the usual Conference of Midland Centre secretaries in March. The question of National Federation finance was considered, and the proposed alterations of rules were generally approved. The Emergency Committee were instructed to consider the question of Midland Centre Finance in February. The statement of accounts showed a small balance on the right side. The Emergency, Collective Insurance, and Year-book Committees were appointed. It was decided to call the attention of the National Federation to the action of the National Conciliation Board in sending out circular letters in reference to the importation of work. The President was requested to convey to the National Federation a hearty invitation to hold their next summer meeting in Nottingham. —Condensed from a report received from FRED. W. AMPHLET, Secretary.

ILLUMINATION AS A STUDY FOR ARCHITECTS.*

By JOHN DARCH, F.S.I.

IN submitting this paper to the Society of Architects, the author's object was to draw attention to the present objectionable methods of artificial lighting, to point out a more reasonable and acceptable way, to define the position of the architect as against that of the engineer in this matter, and to touch briefly upon some of the points necessary to a proper understanding of the subject.

The Position of the Architect.

If the examples of lighting that may be seen everywhere have any power of demonstration, it must be conceded that the average architect is not greatly impressed with the importance of good illumination. It is seldom preconceived, and is largely left to the empirical methods of the electrical engineer or gasfitter.

The art of illumination is correlated to architecture and decoration; it is a thing apart from engineering, and independent of the nature of the illuminant, while its rules apply with impartiality to electricity, gas, acetylene, or oil lamps; it is, in fine, a study for the architect. The architect may, of course, employ a specialist; but, even then, he should know enough to judge the work of such a person.

Having dealt at some length with the governing factors of illumination, which were classed under the following heads: (1) physical; (2) physiological; (3) æsthetic; and (4) economic, the author proceeded to consider

General Principles.

The whole case for good lighting is embodied in a very simple axiom—namely, the purpose of artificial lighting is to make readily and properly visible the things required to be seen.

This may be made more definitive by the following rules:—

(1) The lamps or other sources of light to be so disposed that they do not occupy the field of vision; (2) the illumination to be sufficient to cause the objects to appeal at once and with comfort to the eye; (3) for general illumination the light to be well diffused, with a preponderating downward direction, freely flooding ceilings and walls; (4) local lighting to such as desks, benches, exhibits, etc., to be specially suitable and in most cases adjustable in position and power; (5) the colour to be as pure and white as possible. Monochromatic light, as a rule, to be avoided.

A false light makes a false impression, and an interior, no less than a face, can only be its own self when naturally presented. It requires nothing more than common sense, and a consideration of the natural demands of any object to be illuminated, in order to produce truthful and agreeable results.

General v. Local Lighting.

The relative merits of general and local lighting have been the subject of much discussion. Thus, a bank may have a general illumination sufficient for desks and all purposes, or the desks may be locally illuminated with desk lamps from which a small amount of light may escape into the gloom overhead; or, again, there can be a combination of both. Daylight has been quoted as an exemplar in favour of general lighting only, but when it becomes practicable to provide artificial

light equal in quality and abundance to that of freely admitted daylight, nothing could be said against it. It is a question of sufficiency of light, and of what has to be illuminated; each case needing special consideration. In the average public hall general lighting only would be the best, because the illumination at the working level, which would usually be sufficient at 1 ft.-candle, could easily be obtained, and because it is desirable to exhibit the decorative features. A school or reading room would be a different matter, for 3 ft. to 5 ft.-candles would be necessary, and to get this in general lighting may mean a fatiguing blaze of light, and a large expenditure, while any varying local needs could not be met. There are cases where all needs are best met by local lighting only, but the most economical and satisfactory results are usually obtained by a small measure of general lighting combined with an adequate and well-shaded local lighting.

General illumination may be broadly considered as of two kinds, direct and indirect, but there may be modifications and combinations of both.

Direct lighting is that in which the light radiates immediately from the source to the objects to be viewed. Where glass shades are used it would still be considered direct lighting. This method is usually economical and convenient, but it should be used only where it can be made to accord with the foregoing rules, as for example:—(a) Ceiling lights in lofty rooms, where the eyebrows, which are designed to screen the eyes from the sky, will serve the same purposes at night, and in such cases no lights should subtend an angle greater than 30° from above the eye; (b) direct lighting would also be used in places that are normally viewed in one direction, as shop fronts, churches, public halls, picture galleries, etc., in which the lamps may be recessed or screened; (c) under any circumstances where the lights do not come before the eyes.

The author then considered the art of shading, condemning many forms of shade commonly in use, and suggesting better forms for the effective protection of the eyes.

Indirect Lighting

is that in which the illumination is obtained from surfaces illuminated by concealed lights. It usually presupposes a white ceiling and upper walls or other extensive diffusing surfaces—the larger the better. The results are great uniformity of lighting, approaching practical daylight more nearly than with any other system, while admitting of greater distinction of vision and affording comfort to the eye.

It has been objected to this form of lighting: (1) that it has a cold and cheerless effect; (2) that there is a flatness and an unpleasant absence of shadow; and (3) that light is wasted by absorption.

With regard to the first, if by "cold" is meant whiteness of light it is a point gained; nothing but prejudice could prefer coloured light; the ruddy glow of evening may be very beautiful, but we should not like to have it all day.

As to the second, that it is flat and shadowless, it is really not true. Indirect lighting does no more than to relieve the blackness of shadows, just as daylight does, while it puts a soft gradation on

reliefs, as was seen in the photograph exhibited by the author.

With regard to the last, it is a fact that of the total flux of light, a considerable percentage is absorbed, but it is also a fact that more light enters the eye than by a higher intensity of direct illumination and, as stated, vision is much easier.

The means that may be employed are arc lamps—providing they are of the right kind—tungsten glow lamps or incandescent gas in inverted bowls or reflectors on pendants or brackets, or lights may be hidden behind cornices, screens, or in many other forms. Where there is not a suitable ceiling, downward reflectors will be required, but to maintain the principle they must be large and with a diffusing surface. It is absurd to put them under a good ceiling as is often done.

[This subject was then illustrated by eighteen lantern slides from some remarkable photographs taken at night by Mr. Thos. Ritchie, showing the interiors of the Natural History Museum, art class rooms, gymnasium, drawing offices, bake house, cabinet making and dressmaking factories, London newspaper machine room, jewellers', dress, and other show rooms, and also a church, all amply illuminated—from 4 to 10 ft.-candles—and yet with soft and daylight effect. Indirect lighting from ceiling gave the best results, in other cases 36 in. over reflectors were used. Good illumination was obtained from "semi-indirect" lamps, but they are objectionable on low ceilings.]

The author next dealt with photometry and illuminometry, standard units and nomenclature, lamps and pole curves, and then proceeded to consider

Decoration, Wall Paper, and Reflection

Effective lighting depends upon two factors; (1) the illumination as expressed in foot-candles or lumens—i.e., the light falling on a surface, irrespective of the nature of that surface; and (2) the light absorbing power of the surrounding surfaces.

When an architect decides upon dark oak panelling or deep red wall paper, does he fully realise the extent of its effect upon the lighting, or would he put much as three times the illumination in such a room that in a room with light decoration? Where is the wall paper that has printed on the back of it:—

avg. coeff. refl. 0.42

or whatever the coefficient of reflection may be?

The factor of reflection is of more importance in the illumination of a room than is generally realised; indeed, without some reflection, illumination would be absolutely nullified; the lamp might shine, but darkness would reign. What we do see depends entirely upon the specific absorption of the surfaces before us, both as to luminosity and colour. One ft. candle on white paper would be more than 200 ft. candles on black velvet.

The following are a few coefficients of diffuse reflection selected from Dr. Loos's lists:—

White blotting paper	0.9
White cartridge	0.8
Light yellow paper	0.7
Plain clean deal	0.6
Yellow painted wall—clean	0.5
dirty	0.4
Pale pink paper	0.3
Vermilion or blue green	0.2
Deep chocolate	0.1
French ultramarine	0.05
Black velvet	0.0

*Extract from a paper read before the Society of Architects on January 11th.

The rule for finding the total illumination due to the lamp plus the reiterated reflections, in the simplest case of an enclosed room, is:—

Total illumination = $I(1 + k + k_2 + k_3 \dots k_n)$
where k is the coefficient of reflection and I the initial illumination; k being less than unity, the above may be thus stated:—

$$\Sigma I = \frac{I}{1-k}$$

from which it may be seen that if a room lightly decorated has a coefficient of reflection of 0.7, the total flux of light on any surface would be $3\frac{1}{3}$ times that of the initial illumination. If, however, we take a case of dark walls, etc., say, k 0.15, the total would be only 1.17—no increase worth speaking of. In practice, secondary illumination adds from 25 per cent. to 100 per cent. of that from the lamps.

Of no less importance is the physiological aspect of contrasts against dark backgrounds, to which reference has been already made.

The author by no means advocated white interiors. Uniformly white interiors are fatiguing to the eye if not to the mind; if white is used, it should be varied just as soft shadows vary relief surfaces. If a darkly decorated room requires more light to lighten it, such depth of colour serves no better purpose than to eat up costly light. According to Fechner's law of sensation, contrasts in light and shade are relative and not absolute, and the relation being fixed we are unable to judge of absolute intensity; so that any scheme of decoration on a somewhat lighter scale may equally meet the artistic sense and afford considerable advantage in illuminating value.

The eye needs relief and rest, and the lower part of a room, where the value of reflection is small and where the eye more naturally falls, is the best place for darker areas. Hence, floors should be dark, and dadoes are desirable, but not in too strong contrast to the upper walls.

Practical Application.

This paper will be concluded with a few notes on the practical application of the foregoing to churches, schools, hospitals, public libraries, and factories—chosen to afford as large a variety of treatment as space will allow. The important subject of domestic illumination was too large to be included in this paper.

Churches.

The simple-minded person would suppose that the beautiful decorations of many churches are placed there to be seen; but go into the first church you may meet, during full evening service, and you will probably find that the upper two-thirds will be lost in a gloom that is heavy and depressing, while the lower third will be largely obscured by dazzling points of light, and the chancel scarcely visible; every face will have a hard patchy appearance due to want of diffusion, and the preacher is at all interesting two vexatious pulpit lights will send you home with smarting eyes.

It is not a question of brilliant lighting *versus* the mystic gloom, which some architects have advocated as conducive to worship. The "dim religious light" of a morning service may have its charms, being usually relieved by softly illuminated surfaces that can be seen with comfort; but the obscurity of an evening service, pierced by obtrusively brilliant points that dominate everything and refuse a haven of rest to the baffled eyes, is not likely to be helpful to worship—excepting by way of penance.

This is but one point of consideration amongst many to be found in church lighting.

Treatment will depend upon the style of architecture and many contingencies. Sufficient light for practical purposes is the first consideration— $1\frac{1}{2}$ ft.-candle at the pew level; the next is eye comfort, and another is to make the building and its decorations easily and agreeably visible—a quiet general light is all that is required. Chancels are effectively illuminated by lights behind the chancel arch or other projections; the Guards' Chapel in St. James's Park is so treated, and has a sublime effect. The pulpit and reading desk require 4 ft.-candles, Notices and inscriptions should be illuminated. Avoid what has been already described as decorative lighting.

Schools.

The author had examined a number of modern elementary schools, and generally speaking had found the artificial lighting to be (a) insufficient; (b) too uneven, having usually but four gas or six electric glow lamps to a class of 40 children, and these too near the centre of the room; (c) in the class-rooms unprotected lights in nearly every case in the direct range of vision of both scholars and teachers; and (d) the blackboard, which needed more, really had less light than elsewhere, to say nothing of the gloss.

Dealing with the class-room only, there are three methods of lighting, either of which may be made satisfactory.

(a) Indirect illumination by high-power lamps illuminating a white ceiling and frieze.

(b) Direct lighting from ceiling lights pendent about 2 ft. to get diffused light from ceiling and not placed centrally, but nearer the left-hand window.

(c) If pendants, reaching to 6 ft. or 7 ft. from floor, are continued to be used, there should be eight or ten of them, where there are now four or six, and each should have opaque shades in which the light can be entirely recessed. A form shown by the author would, he explained, serve also for general illumination, for where it is adopted the ceiling and walls are fully illuminated; the eyes will be protected and the greater intensity concentrated on the desks, where it should be a minimum of 3-ft. candles. For pencil drawing and needlework, special desks or tables should have an illumination of 8 ft.-candles.

The wall at the teachers' end is the exhibition screen, and should be specially lighted with screened lamps giving an illumination of 5 or 6 ft.-candles.

Hospitals.

It had been the author's privilege to inspect many of the principal London hospitals with special respect to their lighting arrangements, and where everything else is so very admirable the artificial lighting reminded me of Miss Nightingale's trenchant observation, that "the very first requirement in a hospital is that it should do the sick no harm." There is, obviously, a universal want of discrimination in the modes of lighting, the fittings were generally found to be inappropriate, and the "shades" afforded no relief to the stinging points of light that were exposed to the eyes of the sensitive patient and that to the lower and weaker part of the eye.

Briefly, the ward unit, of, say, twenty beds, should be provided with a general illumination of about 0.5 ft.-candles, with protected or indirect illumination.

The sisters' and nurses' tables should have lamps adjustable—without dusty cords—to from 3 to 8 ft.-candles, the latter for dark needlework, with dark shades that will entirely recess the lamp—preferably dark green opal. The patients' lights are too often conspicuous by their absence, the nearest light, usually a single glow or gas lamp, being 12 or 14 ft. distant; there should be a screened light at the head of each bed, placed low behind and on one side of the head, giving an illumination of 3 ft. candles, and adapted for use for medical examination.

The dispensary is usually the worst served; dispensers have complained of the worry of reading the prescriptions in the inadequate light, while many bottles stand in semi-gloom. A shaded light, giving 4 or 5 ft.-candles, is required to each man; the shelves should be illuminated with screened lights, while special facilities are desirable for reading the graduated measuring glasses.

The operating theatre calls for special consideration, for there is a large amount of surgical work done after dark. Here, again, there is no established form of lighting; each hospital having its own arrangement, not all satisfactory. The essentials to success may be thus summarised: (a) White ceilings and walls, pale grey or green dado and darker floor; (b) separate general illumination with screened lamps over the sinks and sterilisers; (c) the lights to the operating table should not be clustered together as they commonly are—forming black shadows—nor be placed directly over the table, whereby the surgeon's work is obscured by his own head and hands; (d) lamps must not radiate heat on the patient or on the surgeon's head; and (e) all septic risks must be avoided; therefore, there must be no dust creating cords and pulleys or fittings, and glass must be smooth and easily cleaned. Well-made arc lamps may be used, either (a) direct-lighting, white flame arcs placed over a diffusing ceiling light, or where there is no skylight, indirect lighting—both affording a splendid light. There is an excellent scheme in practice in Germany, wherein isolated beams of light are concentrated on the table from a projector lamp outside the room, whereby dust, heat, and the intrusion of workmen are quite precluded.

Libraries.

There is, perhaps, no greater tax on nervous energy than continuous reading of educational literature; it is important, therefore, that the further burden of eye strain should not be imposed on the reader by misplaced and inadequate lighting. Better the plainest building where the books can be read in comfort than a marble mausoleum of literature that chills enthusiasm and worries the eyes of the student. I have seen many handsome libraries, but not one properly illuminated.

The ordinary library requires a small measure of well-diffused general lighting—0.5 to 0.75 ft.-candles. The principal feature, however, is the local lighting, which should consist of (1) a separate light to each reader—on his left—with an opaque or semi-opaque shade; (2) every desk lamp should be adjustable so as to permit of a modification of from 2 to 10 ft.-candles, and under the reader's control—anxious librarians may have them made "fool-proof"; and (3) the reader should be expected to switch on and off his own light, which would effect a great saving.

The news stands are always well patronised. A good light is wanted for them, as newspapers are not so easy to read as a clearly printed book. The author showed an illustration of waste and bad lighting, in which a lamp doing duty over a double desk gave but an illumination of 0.32 ft.-candles, a pitiable result from a 30 candle-power lamp, apart from the shadow nuisance of the puckered paper. In contrast to this there is in Cripplegate Library a stand with pairs of bracket lamps of 8 candle-power each so placed that it gives $3\frac{1}{2}$ ft.-candles on the page—ten times the illumination, with half the expenditure of light, and no shadows. These are not, however, all that they should be, for whichever way you look the glowing filaments hit you. This could be easily obviated by the use of deep and dark shades directed towards the desks.

Where will you find book racks so illuminated that the titles can be deciphered without practically having to dab one's nose on the books? Where is the glazed indicator in the lending department that can be read without being bothered with gloss? Do architects ever think of the irritation caused by the upward reflection from polished table-tops?

Factories and Workshops.

Holland is the only country that has framed an Act that properly stipulates the amount of light to be provided, and where such as embroiderers, jewellers, and draughtsmen are required to have a minimum of 15 bougie metres (about $1\frac{1}{2}$ ft.-candles), and all others 10 bougie metres. British legislation is confined to enamelling shops and underground bakehouses, which are, respectively, to be "efficiently" and "adequately" lighted, expressions which mean nothing in particular, and therefore useless. Definite legislation is urgently necessary, for there is still an overwhelming majority of workers under conditions that are ruinous to eyesight and health.

In machine shops the majority of accidents are said to occur after 4 p.m., and no wonder, for brilliant points of light against a dark background must baffle the eyes and deceive as to distances. What is wanted is a well-diffused general light, aided by whitened and illumined ceilings and walls. Nothing is better for this purpose than indirect lighting. Screened local lighting should then be added to all points requiring the attention of operatives and to benches, desks, etc. Money spent in a liberal lighting of factories and workshops is repaid a hundred-fold in better and more work.

DISCUSSION.

Mr. H. Freyberg, F.S.I. (London), in proposing a vote of thanks to the lecturer, said he thought it would be impracticable to have a light for each reader in a library open to everybody, and to trust to the readers to switch the lights out when finished with. He agreed with the lecturer that the illumination of schools had been shamefully neglected. He remembered his own schooldays, and how badly the form rooms were lit. It was nothing less than their duty to see that the sight of the rising generation was preserved by carrying out proper methods of illumination.

Mr. B. R. Tucker, M.R.San.I. (Past Hon. Treasurer), in seconding the vote of thanks, said that one of the chief points which architects had to take into consideration was the question of cost. They were limited to a certain expenditure by

their clients, and that limit left very little to be devoted to any special scheme of lighting. Light in its travels diminished in an inverse ratio to the square of the distance, and they could not afford the amount of light necessary for lighting a room by reflection from the ceiling, owing to the great amount of light lost. It might do for public buildings, but for private habitations it was out of the question.

Mr. Justus Eck said, as an electrical engineer, he was one of those people whom Mr. Darch had aimed a shaft at, and it would be a pity to take to heart too seriously all that the lecturer had said regarding the bias of experts. It was to be regretted that Mr. Darch had not referred to daylight illumination. From what was seen around them, it would appear as though architects in the past were not quite certain whether a window was a ventilator or a lighting device; but the study of papers like the lecturer's would no doubt improve the illumination of buildings both from the daylight and the artificial lighting point of view. The importance of artificial lighting being as similar as possible to daylight had not been sufficiently impressed. Beautifully decorated buildings were seen to great advantage by daylight, and it was important that the effect produced on the eye should not be destroyed or minimised by artificial light. His experience, when approaching architects with a view to the use of arc lamps, was that they invariably declined to consider their use owing to their appearance, although he saw no reason why arc lamps should not be made an artistic feature.

Mr. H. Mackinnery said that architects could have every confidence in the illuminating engineer, even if they were experts in one particular direction. He himself was interested in one form of lighting—the application of tungsten and metal filament lamps—but he had on more than one occasion recommended the use of other lamps. They, as illuminating engineers, endeavoured to forward the industry, and not personal interests. There was a difference between the actual effect of daylight and illumination by artificial light. In daylight the surroundings were very bright, and exercised a controlling influence on the aperture of the pupil of the eye, whereas to illuminate a room artificially with many foot-candles would mean the use of a concentrated light producing very dark surroundings.

Mr. J. S. Dow felt that there must be many instances where an architect required a certain arrangement of lights on account of the architectural features of a building, and such arrangement would be governed by quite different factors from those which illuminating engineers usually employed. He hoped that on some future occasion a paper by an architect would be read before their society on this subject.

Mr. Darch, in reply, said that the architect was the man who held the key to the situation. If he would only turn his attention seriously to questions of lighting, he could do more for them than any other person. They would do more good by spreading the gospel of illumination among architects. Mr. Freyberg had suggested that readers could not be trusted to turn out the lights, but he (the speaker) thought they could. Many large public libraries at the present time were fully lit for one or two readers, and he thought that was a greater waste than if one or two were left on by readers

under the system he proposed. Mr. Tucker had said that indirect lighting could not be adopted in many cases owing to its cost, but he was of opinion that, light for light and effect for effect, it could be installed at an equal cost with direct lighting. It was not the fact that light lost by reflection within a room. There were of course slight variations, but inside a sphere it had been proved that light was not lost whatever the size of the sphere. He had also said very definitely that daylight should be the guide to artificial lighting.

THE LONDON LABOUR MOVEMENT

The notice given by the London district of the Amalgamated Society of Carpenters and Joiners of demands for increased wages and shorter summer hours was considered at a meeting of the masters last Thursday, January 18th, but no decision was reached. It is expected that the two sides will meet in a conference, but as the men's notices do not take effect till June 8th the negotiations will probably go on for some time before a definite answer is given.

The demands, as has been already stated, are for an increase of wages from 10½d. an hour to 1s., double pay for overtime, and a reduction of summer hours from 50 to 47 a week. These are considered by the masters to be exorbitant. Their view is that the brighter prospects which the building trade is beginning to enjoy after a period of stagnation lasting for five or six years would be checked by such a considerable increase in working expenses. The prosperity of the trade is dependent to a great extent on the enterprise work on speculative lines in the suburbs, which is largely undertaken on borrowed capital. The proportion of failures in the trade in the last few years has been high, and it is pointed out that any such substantial rise of wages as would threaten the stability of speculative builders would tend to discourage the flow of capital to the industry. The employers complain also of being hardly hit by recent legislation, in particular by the Insurance Act and the Workmen's Compensation Act. In addition to the contributions for invalidity insurance, they anticipate a heavy burden in connection with the unemployment provisions, the building trade being one of the three groups of trades to which this part of the Act applies. Complaint is also made of the uncertainty as well as the weight of the liabilities imposed on builders by recent Finance Acts.

Proposed New London Exhibition Building

It is stated that arrangements are being made for the formation, on an extensive site near Buckingham Palace of a huge exhibition of the type of Olympia. The details, however, are not yet available.

JANUARY 29. ADDITION TO CENTRAL POLICE AND FIRE STATION, SWANSEA.—The Corporation of Swansea invite design for additions to this building, including the provision of a new police-court. The successful architect will be appointed to carry out the work. Names to be sent to Mr. A. D. Jenkins, Borough Estate Agent, 3, Prospect Place, Swansea, before January 29th.

Architecture and Painting.

HE two papers read at the last meeting of the Institute of Architects, under the heading "Colour as Applied to Architecture," did not cover exactly the ground which one would have expected from the title. They dealt really with the question of the relation of the art of painting to the art of architecture, a very important

and very interesting subject. But before we come to that, which is the union of two arts, there is the subject to be considered of the part which colour may play, purely as colour, in heightening and assisting the effect of purely architectural detail. This part of the subject seems to have rather dropped out of notice, except in a sentence or two in Mr. Edgar Wood's paper; but it is the most distinctly architectural phase of the subject, and should have been considered first.

There has always been a difficulty in settling the relative claims of contour (or profile) and colour in reference to architectural detail. The subject divides itself into the two problems of the treatment of modelled surfaces or mouldings, and of flat surfaces. Mouldings produce their effect by gradations of light and shadow. The application of colour to the different mouldings of, say, a Gothic arch, has the result of weakening the effect produced by gradations of light in delicately profiled mouldings; the arch-moulding becomes a series of bands of colour, which impress the eye more strongly than the light-and-shade effect produced by the profiles of the mouldings; and in those styles of oriental architecture which employ colour largely we generally find that there are few mouldings, and those often of rather poor profiles. In the highly coloured styles of architecture, it seems to have been felt that colour was enough, and modelled surfaces were of less consequence, and in fact, interfered with the colour effect. Apparently one cannot have both effects, modelling and colour; one interferes with the other. The reason for this is suggested in Mr. Wood's remark that colour is emotional, while form is a matter of intellectual perception; and "in the East the emotional instinct proved too strong, and everything is sacrificed and surrendered in order that colour may become the all-powerful appeal." It is a question of sunlight to a great extent. Strong sunlight brings out colour effect with great brilliancy, and even seems to create the desire for it; and architecture becomes rather emotional than rational. The Renaissance in Italy was purely a rational movement, and, as the writer of a good article in the "Times" observed, the great Renaissance architects "designed entirely in plainness."

Architectural materials which have strong inherent colour, such as polished marbles, are adverse to the effects of moulding; the lights and shadows of the moulding do not come out. What we seem to need in constructional polychromy is the massing of colour by the opposition of broad expanses of material which contrast, but harmonise in colour. Much more might be done with this, and the effect much broader and more reposeful than the insertion, for instance, of marble and granite columns in a façade mainly of neutral-tinted stone. These, like the Purbeck marble

shafts in some of our cathedrals, disturb the unity of the architectural design, and are rather a commonplace source of effect.

In buildings in which the main lines are accentuated by moulding, the employment of bright and decisive colour is better left to the flat interspaces of the design. Externally, such a material as mosaic supplies this; internally, it has never been done so well as by stained glass; and it is important to remember that, as far as regards stained glass, the subject—in other words, the story portrayed—is of less importance to the general effect than the colour, and the pattern which it makes. Pictures of events in stained glass are seldom (we might almost say never) successful; it is demanding too much of the material. Stained-glass design should symbolise rather than illustrate a subject. And its colour is its most important element. In stained glass we have a source of colour-effect which, rightly treated, has something architectural in style about it, and takes its place as a decorative portion of the architecture; and it is hardly effective apart from an architectural framework. It is not, properly speaking, a pictorial art, and that is why it blends so well with architecture.

When we come to mural painting, and to painting generally, we then have to consider an art which is much more than architectural decoration. That was the real subject of the two papers at the Institute; and it means not architectural decoration in the ordinary sense, but the harmonious combination of two arts. In Sir Alfred East's paper there are some important points to be noted. In the completion of any public building, he thinks, the architects should be absolutely responsible; that is, that if it is to be decorated with mural paintings, the architect and the painter should be, as it were, in collaboration from the first; each should have some general knowledge of the art of the other. The result would be, that the architect would know beforehand what subject the painter was to treat, and what space he would require; and would arrange that space so as to have a good lighting for the picture; the pictures and the building would be planned together and make one whole. That is a counsel of perfection, and we doubt if it has ever been realised in this country. Generally speaking, some spaces on a wall are found suitable for mural painting, or have been left for that purpose, and a painter is invited to paint on them subjects illustrating the history of the city, or something of that kind, which may prove not to be decorative at all in the sense that the architect would like. The moral is that the intended mural decorations of a public building should be settled in advance, the painter appointed in advance, and the architect and painter work together from the first.

"But," says Sir Alfred East, "what shall I say to the architect who designs a private house and leaves no space for sculpture or painting?" That is an old complaint revived. A good many years ago, the late Mr. John Brett declared that there were hardly any houses in London where a picture could be hung in a good light, and he induced the Council of the Royal Academy to offer their architectural prize of the year for a design for a town-house with rooms which would have a good light for pictures. Sir Alfred East evidently has much the same opinion; he thinks that one of the causes of the decline in the purchase of easel pictures is that neither the architect nor the commercial

decorator ever considers that it is possible for the cultured man to be interested in the arts of painting and sculpture. We should doubt that being the reason; the decline in the purchase of pictures is more likely to be because times are bad; a man who has plenty of money and who has a love of pictures will be likely to purchase one that he admires, without any consideration as to whether his house has a good position to hang it in; he will get it in somehow. But we fear it is too true that an architect, in designing a house, does not sufficiently consider whether the client has pictures or sculpture for which he wants a good position. It is certainly a point to be considered. Perhaps, on the other hand, it may be said that the client ought to inform the architect what pictures and sculpture he wants provision for, and not leave it to chance. At all events, the suggestion is one to be borne in mind by architects who are making plans for a house, and probably it very seldom is.

In regard to the mural decorations of public buildings, it is pointed out by Sir Alfred East that the painter is often called upon to paint an historical incident, and he has then the difficult task of endeavouring to arrange his composition so that, while illustrating his subject, the contours and the qualities of colour may be such as to have a decorative effect; and to the contours of colour Sir Alfred East attaches much importance. That is one of the most original points in his paper. All form is expressed by either straight lines or curves; the bounding contour of a mass of colour must be either straight lines or curves; the result may be very different, in a mural painting, in regard to its harmony with the lines and style of the architecture. We may as well quote his remarks on this head, for the point is novel and important:—

"The question arises, naturally—what is the best form, the most suitable form, by which we may display a particular colour at its best? That is a difficult question to answer, and if it is a difficult one in a single instance, how much more difficult and complex does it become when there are several colours to be placed in conjunction! and, after solving this problem, as far as colour is concerned, we have then to consider if the conjunction of colour we have accepted is such a one that will conform to the special conditions of the building to be decorated. This is a difficulty, and one that may be presented to the painter with varying results, according to the conditions presented by each particular building. He has to consider the masses and details of such a building to be decorated; his decoration should be so sensitive that it should support not only the larger masses of the structure, but each detail by which the architect has himself embellished his structure. He must be as sensitive as the architect in sustaining the purpose of its being; he must not in any way destroy or warp such an object; he has no right to take away the knowledge that there is a surface on which his painting is superimposed, or remove by some optical illusion any structural quality of the building which is necessary for its support. All these things he has to consider, and, if he were a great decorator, he would consider these; but, if he be a victim of some local authority, who dictates to him what he shall do, or how he shall do it, then failure is certain."

As a subsidiary question, it is asked whether, if there be no historic incident to record, the painter would not serve the architect better by substituting decorative landscape in place of an incident painting. In France there is a great deal done in the way of decorative landscape—some which is rightly called so, some which is not; it is important to remember the distinction. A decorative landscape is one treated so far in a flat and conventional manner, that it becomes a suggestion of landscape rather than a realistic presentment, and therefore does not do away with the sense of the wall's being there. A landscape painting in the full and complete sense of the word cannot be painted as a decorative mural picture, because it does away with the wall, and substitutes a view into a distance. If this distinction is borne in mind, decorative landscape may be a very pleasing and successful means of bringing colour into interior architecture.

Mr. Wood seems to have adopted the idea that has been often promulgated of late, that pictures are nothing except in connection with a scheme of decoration, and that the easel picture is self-condemned as a mere portable work having no relation to the architecture. With this we cannot

agree. Painting has a life and a value of its own, quite independent of architecture. If an owner had a definite number of pictures and had a room designed with wall-panels adapted to their shapes and sizes, so as to enshrine them in an architectural framework, that would no doubt have a more decorative effect than hanging them separately, in an obviously temporary manner, on a wall. That has been done in the room at the Louvre, specially designed for a series of pictures by Rubens, with excellent effect. There are many difficulties in following out that kind of scheme in a private residence. There is the uncertainty in the fixity of tenure in a house in modern times; not like the days when houses were built with the intention that they were to remain the family mansion from generation to generation. Then, before a definite architectural framework can be made for a private owner's pictures, he must be satisfied that he has completed his collection and does not want to alter or add to it; and that can seldom be the case. The best thing is, perhaps, to design an architectural framework for the most important pictures, which are likely to be permanent, and leave the remainder to be hung in a removable manner on the wall. To those who say, like Mr. Wood, that this is an undecorative way of using pictures or of treating a room, the answer is that the best pictures have a value of their own, higher than any decoration; and the placing of a picture in a gilt frame (gold being the great separator and harmoniser in connection with colour) sufficiently divides it off from its surroundings to give it a separate life of its own. To condemn "easel pictures" because they cannot be made part of a scheme of mural decoration is absurd. Many of the finest pictures ever painted have been easel pictures; the art of painting at its highest is of more value than any mere decoration, and those who only regard pictures as part of a scheme of decoration show a very inadequate appreciation of the art of painting.

Westminster Abbey and the Monument Question.

THERE is room, perhaps, for some further comment on the subject of Westminster Abbey and its monuments, on which a correspondence has lately been going on in a leading daily paper; a correspondence provoked by an unguarded expression as to what was held to be the duty of "clearing away some of the rubbish which defaces the Abbey." We call it "unguarded," because the journalist who wrote that light-hearted sentence could hardly have been thinking very seriously of what such an opinion really implies.

How the Abbey first came to be regarded as the special place for the memory of an eminent man to be commemorated by a monument it is perhaps rather too late now to enquire; it is ancient history. The Abbey was regarded, one may suppose, as the national church, having a far greater antiquity than St. Paul's, besides having been for centuries the coronation church of our kings; and as man, eminent in his parish or neighbourhood, is given a monument in the parish church, so it was thought that man who had deserved well of the nation at large should have a monument in the national church. As long as there was plenty of space, the honour of a monument in the Abbey was granted pretty freely, especially to military and naval commanders who had more or less distinguished themselves; and monuments were erected to reputation far slighter than would be accepted for any such claim to-day. The majority of these monuments were erected at a time when architectural taste was entirely at variance with the form of architecture represented by the fabric itself, and some of the most bombastic and tasteless monuments commemorate reputations which have now shrunk to very small dimensions; one might say, indeed, that the size and scale of the monuments seems almost in inverse ratio to the scale of the reputations. Thus the Abbey has been crammed up, it may be fully admitted, with a medley of monuments quite out of keeping with the style of the church, and a good deal of the detail of the ancient walls has been defaced or cut into to make room for them.

We may cordially wish that this had been different; that the monuments had been better designed, and kept, in most instances, to a smaller scale; and that, if they could not be expected to be in the same style as the building, at a time when all the spirit of mediæval architecture had died out, they should at least have been arranged, as to size and position, in some symmetrical relation with the architecture. But to talk of removing them now is another matter entirely. The position is summed up neatly in Mr. A. C. Benson's phrase: "I do not for a moment say they were right to put them up, but I am quite certain that we should be wrong to take them away." The reasons for this conclusion are twofold. First, a monument erected in former times to the memory of any one who was honoured in his own day ought to be considered a sacred thing, not to be touched. If it is to be accepted as a principle that a monument erected in good faith as a memorial is to be liable to removal or demolition at any time when a future generation finds fault with its taste, there is no security for the permanence of any monument whatever. We do not know what a future generation may think of some monument which satisfies our taste to-day; and if we pull down the monuments erected by our forefathers, our descendants may logically conclude that they have an equal right to pull down ours. On such a principle there is no security for any monument whatever. The second reason, which is perhaps an even stronger one, is that the Westminster Abbey monuments form an exceedingly interesting chapter of history. They not only recall the memory of a good many actors in the past life of the nation, but they form an object lesson in the history of our national taste, or (as some may say) want of taste. Human history is even more interesting than the history of Gothic architecture, and the Abbey monuments form a chapter in it which we cannot afford to efface.

A minor reason for not disturbing them, which is mentioned by Sir W. Richmond, is that the removal of many of them would undoubtedly leave bare spaces where mediæval masonry or detail had been cut away or defaced; spaces which would have to be made up with modern Gothic detail which would have no interest at all. The monuments are, in their way, a reality; their former positions would have to be patched up with unrealities. We have called this a minor reason, but it is one not to be overlooked. We may also add that the eighteenth-century monuments are not all as bad as they are called. There are works among them, some of them bearing the names of sculptors not undistinguished in their day, which have considerable merit as designs; though these, we admit, are mostly among the smaller and less prominent examples.

The second proposition made by the "Morning Post" was that it was time that some definite decision was come to as to the number of new monuments to be erected in a building already so crowded with them. Of course it is. The *entrée* to the Abbey can no longer be open to minor reputations. It has become a more decisive honour than it used to be, since it is evidently impossible now to consent to the erection of new monuments except in the case of men whose title to fame is really of the highest, and is universally admitted. And unless we are to have an entire dearth of great men in the future, which one hopes may not be the case, it is obvious that in a short space of time it will be practically impossible to find space for any more monuments. It is, therefore, of some interest to find Sir W. Richmond reviving the idea, which was much talked of a good many years ago, of building some kind of special annexe to the Abbey for the reception of future monuments; an annexe so arranged as to be practically part of the Abbey church, so that the traditional honour of commemoration within the Abbey may still be kept up.

At the time of the discussion referred to, one suggestion made was that a new national Campo Santo should be erected on the open piece of ground, at present laid out as a public garden, at the south end of the Houses of Parliament. This was rather a fine idea; only it would not carry with it the traditional honour of a memorial in the Abbey. It would grow to have a traditional honour of its own in time,

but for a century or two it would be a new site with no tradition. To satisfy the traditional feeling it would be requisite to add to the Abbey some kind of annexe which would form part of the interior. This may seem a very dangerous thing to talk about, but if carried out with judgment it might be done so as not to be open to the charge of irreverence to the ancient building.

There are three ways in which such a thing might be done. One is, to do what was actually done at the Portuguese abbey church of Batalha; to add to the Abbey, at the west end, an octagonal building specially designed as a monumental chapel, and connected with the west door of the Abbey by a porch common to both. At Batalha the monumental chapel was added at the east end, but that is only a question of conditions of site. In London the monumental chapel might occupy the ground occupied by the rather unfortunate temporary edifice put up for the coronation. The architecture of the Abbey at the west end is of much less value than that of Henry VII.'s chapel, and would not be interfered within any material way by the octagon chapel, except being partially concealed by it from some points of view. This kind of octagon chapel for monumental purposes has architectural precedent: there are other examples besides Batalha. It could hardly, however, be a very spacious one. A second expedient would be to form a new cloister on the north side of the nave, for which there is plenty of room. The third, and we think the best, would be the erection of a new north aisle to the north of the nave. The existing outer wall of the north nave aisle has been very much restored or refaced, but in any case it need not be much interfered with; it would only be hidden from view from the outside. Our idea is that openings would be made in the lower portion of the existing wall, so as to give free circulation into the new aisle and make it part of the church; and the existing aisle windows would merely have their glass taken out, and remain as traceried openings into the new aisle.

This proposal was actually put forward at the time when the whole subject, as we have already mentioned, was largely discussed some twenty or five-and-twenty years ago, and the idea was received with a good deal of favour at the time. As for those who would call such a proceeding "vandalism," and so on, we can only reply that there has never been any time, when architecture was a living art, when men were not ready without scruple to add to an older building whatever was necessary for its new or more extended purposes, often without the slightest care even to assimilate the style of the additional building with that of the older one. Henry VII.'s chapel itself is an example.

The Wellington Monument.

IT is a satisfaction to see Stevens's great monument at last completed as he designed it; though one cannot help thinking sadly of the years of struggle which the sculptor went through over it, amid an official generation which had little sympathy with him and little understanding of his genius. To some extent he may have given cause for dissatisfaction by a dilatoriness over the work which even now it is not very easy to understand, but which probably arose from the fact that he was an artist peculiarly sensitive and hard to please over his own work. Michelangelo, no doubt, would have turned out such a monument in two or three years; but he was one of the men of genius who enjoy also a robust temperament, sure of their powers, and not sensitive to criticism. Stevens, with a genius somewhat resembling that of Michelangelo, was evidently widely different in personal character.

The Wellington monument has undergone a strange history, too characteristic of the way we treat works of art in this country. The equestrian statue, which was intended to form its terminal, and for which the upper portion was specially designed as a pedestal, was condemned by a Dean as an unsuitable object in a church, and the work left manifestly incomplete. Then it was set up in a side chapel where it could only be seen as a silhouette

against the light. Nor is its present position quite satisfactory from an artistic point of view; it is too lofty for its situation under the arch, which presses down too closely over the crowning figure. Its real position, both in an architectural and sculptural sense, should have been in the centre of the nave; but one can understand that there would be ritualistic objections to such a position; it would have been thought too like the intrusion of a secular monument into the centre of a place of worship. But it is a pity; it would have had a grand effect in that position.

Now that the equestrian statue is in its place, it may be said that its execution, from the rather rough models left by the sculptor, is exceedingly satisfactory; nor does it appear by any means too large in scale for the rest of the work; in fact, it appears smaller and less prominent than might have been expected. It was well judged of the sculptor to represent Wellington bareheaded; the introduction of the orthodox cocked hat would have given the figure a prosaic and too realistic appearance. What is to be regretted is that the height of the monument and the conditions of light are such that it is hardly possible to see properly the two grand supporting groups of sculpture. On a very bright day it may be better, but we have unfortunately so few very bright days; and under ordinary circumstances only those who have seen the model of the "Valour and Cowardice" group at a lower level in the South Kensington Museum will be able to realise its power fully; the spectator who sees it only in its present position will have to take it a good deal on trust. The whole monument could only be really seen and judged of properly, in its sculptural details, if it were placed in an arena with raised steps around it, so that it could be looked at from a higher level than the floor on which it stands.

As an architectural and sculptural composition it is entirely satisfying; there are some minor details which are not quite so good. Had such a monument been carried out in France, the sculptor would have been required to work in collaboration with an architect; and in that case probably we should not have seen the rather ragged-looking relief ornament on the surface of the plinth moulding, which is not very architectural in feeling; nor probably should we have seen the rather weak detail of the realistic rope knots in bronze which divide off the panels on which the names of the battles are inscribed. Sculptors seldom fully understand architectural detail of this kind. The finest detail of the whole work, except, of course, the bronze figure groups, is the treatment of the bronze sarcophagus, solid and monumental in effect, yet with a fine elaboration and flow of line in the decoration.

With the recollection of this detail in one's mind, it is very annoying to see, when leaving the cathedral by the west doorway, the two wretched lamp-posts which stand on the blocking against which the steps abut at each side. They look like common street lamp-posts put there as a makeshift. Surely there ought to be something better designed, more worthy of the façade, to occupy this prominent position in connection with it.

The Legros Exhibition.

THE collection of works by the late Professor Legros, at the Society of Fine Arts, gives a remarkable impression of his artistic genius. One feels as if looking at a collection of works of an Old Master, so far are these from any of the fashions of art of the present day. The small sepia drawings and etchings are remarkable for their combination of human pathos with a keen perception of composition. In his portrayal of human life Legros was in art rather what Crabbe was in poetry; it is not the beauty so much as the pathos and misery of life that he portrays; but in all these scenes he never forgets to be an artist in line and composition. His landscape sketches, often slight, always have a largeness of scale and effect; and the two large landscapes in oil that are included are different in character from any other contemporary landscape painting; low in tone and colour, but perfectly complete in their balance of composition and effect; the "Souvenir of Burgundy" is especially fine. "The Storm" with an old cottage in the centre of the picture,

under a threatening sky, is exceedingly powerful. The design for "A Basin with Masks and Children," for execution in silver, is an evidence of the versatility of his genius.

The Proposed New Guildhall Galleries.

THE extensions to the Guildhall, on which it is proposed to spend £50,000, are to include, it appears, new picture galleries for the permanent collection and for loan exhibitions; three galleries, each 70 feet long, and various smaller rooms, and it is hoped that these new galleries will form an additional inducement to owners to give or lend important pictures. Now is the time, therefore, to consider the question of the best method of lighting these galleries. A great deal has been said recently about the mistake in lighting the new rooms at the National Gallery whereby the light is concentrated on the centre of the room instead of on the pictures. Discussions of this kind are of no value unless they lead to practical results, and the point ought to be fully considered before the new Guildhall Galleries are planned.

National Federation of Building Trades Employers.

TODAY (Wednesday) is being held, in the Balmora Room of the Trocadero Restaurant, Piccadilly Circus, London, the annual general meeting of the National Federation of Building Trades Employers of Great Britain and Ireland. The agenda, always interesting, contains this year many items of exceptional importance. A proposed alteration in the methods of Federation finance may be passed over as a matter of purely domestic concern. Of greater public interest is a proposal to amend the National Form of Contract; and, akin to it, and of similar far-reaching effect is a proposal by the Institute of Builders for a Form of Sub-contract for use where specialists employ made sub-contractors. The details will doubtless appear later, when they may be more fittingly considered in the light of the discussion upon them and its issue. Other items of general trade importance are a suggestion from Yorkshire as to fair-wages clauses in contracts; a proposal as to provisional sums in quantities; the question of standard wages and increased cost of living; the supply of goods to the public at trade prices; the expediency of closer alliance with kindred trades; and discussion as to future action with regard to the Insurance Act. The National Conciliation Board rules are to be the subject of several proposals for amendment; and the rules of the national joint agreement with the plasterers will come up for consideration. Added to this very full programme will be the usual election of officers, which, however, is always conducted with businesslike expedition. In the ordinary course, the president, Mr. J. W. White, of Sunderland, will be to be congratulated on a strenuous and statesmanlike year of office, during which he has figured conspicuously and effectually in matters of truly national importance, distinguished from the merely internal affairs of the Federation, will no doubt be succeeded in the chair by Mr. James Wright, of Nottingham, whose position of senior vice-president falls in due rotation to Mr. Frederick Higginson of London. Mr. Wright has been a charmingly unassuming but energetic worker in the Federation movement since 1895. Mr. White's energetic defence of the interests of the entire industry, and the conspicuously general character of so many of the items above enumerated, lead us to point to the very serious question that arises out of this important series of articles which we have printed, "What is Wanted in the Building Trades." The obvious inference is, that large numbers of outsiders, who contribute neither money nor energy to the National Federation, are nevertheless profiting greatly by its labours. This is obviously and flagrantly unfair. But what is the remedy? Probably it lies in the direction hinted at in our article, "Eliminate the unfit, as is done in Germany, by compelling a man to show just cause for assuming the honourable title of builder, and but very few of those who obtain the credentials will find it expedient to remain outside the organisation which, it is hoped, will in due time be able to secure for them this recognised status."

ON THE NEED FOR AN ENGLISH SCHOOL OF ARCHITECTURE.

AN INTERVIEW WITH PROFESSOR REILLY.

THE whole question of architectural education as carried out in this country at the present time is raised by the new problems in design set for the Final Examination of the Royal Institute of British Architects; and in view of the fact that the subjects given are cognate to those of the Architectural School of Liverpool University, and included in the Liverpool Sketch-Book, we have thought it of interest to publish the following interview with Professor Reilly, under whose direction the Liverpool School is making such a distinct advance.

Asked what his opinion was on the probable effect of the new R.I.B.A. scheme on the future training of English architects, Professor Reilly said:—

"This new scheme of designs seems to me the most important step in architectural education that the Institute has taken for many years. It is the first frank recognition that training in design should be seriously considered, and that facility in design, like facility in draughtsmanship, can only be obtained by constant practice. Till now we have been apt as a nation to suppose that if the student were well grounded in history and building construction the power to design would follow as some heaven-sent blessing on his labours. All that the Institute, so far, has required has been one design and the making of certain working drawings during the Final Examination. This latter did not, from the subjects set, test so much the student's power of conceiving abstract form as his ability to construct. There might be something to say for this in a merely qualifying examination, such as the old Final. In the new Final, however, the student is invited to show his ability in and his enthusiasm for his art in some direction of his choice, and can obtain distinction therein. With an examination conceived on these more liberal lines it is appropriate that the Institute should ask beforehand for evidence of training in the main business of architects—that is, in designing.

"As to the immediate effect of these designs set at regular intervals, I hope it will be somewhat similar to what has happened in America. Students there work, all over the continent, at a series of problems set by the Beaux-Arts Society. For this purpose a group of students and assistants will hire a big room and form an atelier, inviting leading architects to criticise their work. These ateliers are either attached to the local school or architectural society, or are entirely independent. A healthy rivalry springs up between the various ateliers, which the building papers assist by publishing the best designs of each. When, therefore, two American students meet, though one may come from the East and the other from the West, they have at once a great deal in common and a great deal to discuss. Each has worked at the same problems, and each can learn something from hearing about the other's solutions. I hope the same results will follow here. I hope the local societies who have to judge these designs in the first instance will form ateliers and offer prizes. I hope in time the scope of the problems will be enlarged—the size of the paper (which is fixed at imperial more for the benefit of the examiners than on the students' account) must very soon be—and that a new enthusiasm for design will bind together into one body all English students of architecture. It is a great step forward that one of each pair of subjects should be a monumental design, to be shown in shaded and rendered drawings. I hope ambitious students will always choose the more monumental subject. By making shaded drawings they will familiarise themselves with solid forms rather than with mere outlines.

"The other subject is meant, I presume, for the country student who may not have the opportunity of school training in design and drawing. But whichever is chosen, the mere fact of working through a series of designs will help to preserve to each student his own individuality. He will learn to express himself, and thereby his ambitions

will be kept alive. He will not be content to remain forever an assistant. This being so, I hope the young architect will claim more time for himself. Masters are naturally a little apt to think only of their own work and not of their assistants' careers. But this will right itself if the proper spirit is abroad, and with all the students of the Empire doing the same designs at the same time I have great hope that a new life and new enthusiasm will arise to the great advantage of our architecture."

"The School of Architecture at Liverpool University has a definite scheme of study based on Greek work, has it not?"

"The school has a definite scheme. To my mind it could not be a school except in a very elementary sense of the word without one. The main idea underlying the teaching is that the students should look at each problem from what may be called the monumental point of view: that is to say, they should seek first in their designs the qualities of unity (especially of plan), scale, and refinement. These are qualities that are included in the idea of the monument, and they obviously are best exemplified in Greek architecture. In this way, therefore, the school designs may be said to be based on Greek work. But the subjects set are modern subjects, and copies of Greek buildings do not, and could not, result, any more than they did in the 'fifties and 'sixties during the neo-Grec period in France. In any case, it is necessary to give students some convention in which to work; if you do not, the school will form a bad one of its own—a group of students will start *l'art nouveau* or something of the sort. You cannot have a number of people working together in one room each using a different style. It is one of the advantages of school training that it provides an atmosphere—a tradition. All we try to do at

PROFESSOR C. H. REILLY, M.A., A.R.I.B.A.

BY W. E. DAVIES.

From "The Liverpool Architectural Sketch-Book."

Liverpool is to ensure that the purest forms are used, and we hope the result works out in monumentally conceived buildings."

"And you consider that it is better to go back to the original source for inspiration, than to reinterpret what has already been interpreted by the Renaissance?"

"Certainly. Why should we trouble about immature styles, except historically? In the days of the Italian Renaissance Greek detail was not known, though even then the best architects, like Peruzzi, by refining on Roman detail reached something akin to it. The same remark applies to the work of Lescot and Goujon. But now that we know the old wine we cannot pretend that the new is better. In the progress towards purer detail the history of the individual architect has recently been the history of the race. Twenty years ago nearly everyone was designing in some Early Renaissance or immature style like Elizabethan or François Premier. Then the same architects took a larger scale and based their work on that of Wren and Palladio, while to-day every competition reveals the presence of a strong movement towards Greek forms."

"The criticism has been made that such training as you adopt at Liverpool is calculated to produce men with one idea only, and that there is a strong tendency towards mere classicism, cold and formal, like the early nineteenth century gave us. What do you say to that?"

"I think you are right in saying that the early nineteenth-century architecture in England was, on the whole, cold and formal. It was so because, apart from the work of the leading men, like Soane, Cockerell, and Greek

Thompson, a great deal of it was little better than copy. A copy—even of a Greek portico—is always a dead thing. The corresponding work in France, however, is a very different matter. Would anyone call Ginain's Ecole Médicinal or Duc's Palais de Justice cold or formal? The fact is, I suppose, the French were artists, whereas we were at that time mainly archaeologists. If we are artists to-day we need fear no undue formalism. With the vast variety of buildings that modern civilisation requires, there need be no fear that one form, and one form only, will restrict St. George's Hall can simply serve the purpose of a hall, a series of halls; it can never make a warehouse or an office building. And if we examine modern American buildings we do not find one idea, one *motif* only, prevailing. What we do find, however, is that one *motif* is selected for one kind of building—as the Pantheon *motif* for university libraries. In this way character is gradually acquired. In time a building with the Pantheon *motif* will in America suggest a dignified storehouse of books."

"But do you not think that, while founding the main lines of design on Greek work, there should always be an attempt to put fresh life into the detail at least, so as to give it an individuality of our own day?"

"Artists are bound to do this. We are not more exacting like our predecessors than the problems we have to solve are exactly like theirs. All I mean by the use of Greek detail and Classic *motifs* is that we should take the highest and finest forms as our standard rather than the half-understood detail of other centuries. To copy that, to base our design upon that, is to-day the merest affectation. It is only logical to go back to the source for inspiration. It is the same in all the arts. The last post-impressionist

movement in painting is, I think, a reaction towards simpler forms and cleaner drawing; the similarity between some of Gauguin's paintings and archaic Greek sculpture is very pronounced."

"Is it not a fact that there is a danger of overlooking the necessities and actualities of everyday practice (such as the average architect will have to face) when attention is so largely devoted to problems of design in 'the grand manner'?"

"Whatever manner we work in, 'grand' or otherwise, becomes an affectation if it is not consistently applied. In no past period of architecture was there one style for cottages and another for mansions. The charm of the former—its character—very often lies in its implicit relation to larger buildings. If you take a town which is largely eighteenth century, like St. Ives, Cornwall, you will find the same square proportions, the same square sash windows and low-pitched roofs in all the houses, from the fishermen's cottages (of which the town mainly consists) to the squire's mansion. Even the smallest cottages have a definite eighteenth-century character, and yet remain cottages—ideal cottages, as the present artist population seems to think. I maintain that the architect trained in what is called 'the grand manner' is more likely to build a really good cottage than the man who has only considered cottages. If he is an artist, or has any taste at all, he will not make the elementary mistake of building a pretentious cottage, but at the same time he will not build one affecting to belong to some other century—early a subtler form of pretentiousness. His cottage should have the same sort of relation to larger work that country clothes by a good tailor have to town clothes by the same man. We know that a trellis porch may add an indefinable sense of style to the squarest, simplest cottage. There is no reason to my mind, therefore, why in the pursuit of a more monumental and more worthy architecture for our public buildings all classes of buildings should not profit. Good architecture is not a trick—he result of a recipe: like any other art, it has its origin in emotion sincerely felt. All that training can do is to facilitate its expression."

"Your opinion is, then, that as regards freedom in the practice of architecture, there is a great deal too much of that element in the present condition of affairs, and that since the beginning of the nineteenth century the greatest curse upon English architects has been their liberty of choice coupled with lack of architectural education, resulting in a chaos of style frequently expressed by the term 'free classic'?"

"Yes, most emphatically."

"Then there arises the question of construction. It is understood, is it not, that this merits as much attention as 'design' itself, when, as a fact, the two are interwoven? And how do you regard in relation to the Liverpool School of Architecture, the claims of modern methods of building, and their expression in architecture? For example, there is reinforced concrete: how do you find an expression for that in work which is based on Greek models?"

"Construction is the architect's technique. As the painter must learn to handle his materials, so the architect must of necessity learn to construct. Nevertheless, I do not believe at the outset in burdening the student with all the minutiae of ordinary building construction and materials. He need not know, for instance, how cement is made. Teach him what is constructable, and only let him design such things. Let him know the average proportion of solids to voids on certain types of plan. He will learn better the details of carpentry joints—of doors and windows even—a little later in his career. Such things anyone can find out when necessary: they are not of the essence of architecture. I think we may easily make construction a fetish, and forget the architect's real position—that of the master-mind conceiving his building as a whole, its masses, proportions and rhythms before a stone is set, and giving to them their high spiritual significance. On the one side there is a spiritual side to a picture as well as a material side, and strangely enough it is the Ruskinians who have chosen the material side."

"As to reinforced concrete, I do not think it will for many centuries lead to new forms of architectural expression. I doubt if it will ever be used externally on any but engineering works. Architectural forms which may in the first instance have arisen out of material necessities in the long process of evolution gain other meanings equally important, or even more so. We use an Order more often to express dignity than for mere strength, and dignity will still be necessary, whether buildings are made of reinforced concrete or not. New needs like those to which the skyscraper answers in America are more likely to alter the terms of architectural expression than any new materials."

"Finally, then, you would like to see the neo-Grec movement an established thing in this country, to the practical exclusion of other styles; that is to say, so that the general body of practising architects might be counted on to produce buildings of good average merit, and closely related to one another in their character of design; just as, for example, the bulk of the work done under the Georges can be designated 'Georgian'?"

"Yes, that is the condition of things I should like to see if you interpret the term 'neo-Grec' sufficiently widely. Schools of design have this great advantage, that while they do not hamper the genius from giving individual expression to his work, they prevent the average man from falling below a certain level. How else can we explain the fact that we see no really bad Georgian work, no really bad Early English, no really bad Louis Seize? The character is everywhere maintained. The average man, when once a standard of taste is established, is only anxious not to go outside it and betray himself. Where there is little cohesion among architects, as during the last two decades, the average man on the other hand is tempted to think himself a genius and to turn things upside down for the mere fun of the thing."

THE UNITY AND DIFFERENCE IN ART AND CRAFT.

BY THACKERAY TURNER, F.R.I.B.A., F.S.A.

ON Thursday last Mr. Thackeray Turner read a paper on "The Unity and Difference in Art and Craft" at Carpenters' Hall, London, this being the first of a series on various subjects by various authors arranged by the Worshipful Company of Carpenters. Turning first to an analysis of his subject, Mr. Turner said it seemed that art must have an element of creation in it—there could not be life without creation. Art could not exist without craft, though the painter and sculptor could of course each be his own craftsman. But craft in a low form might exist without art. The pretty reed work done by the Norfolk thatchers was delightful as a craft, but could scarcely be called an art. There could hardly be art in the things that had been done just the same thousands of times before and on the same lines. The lecturer thought that a distinction should be drawn between the craftsman who was purely a skilful workman and the artificer whose work had an element of art in it; but Mr. Turner added that in his

STOCK PATTERNS OF ENGLISH AND ITALIAN BEDSTEADS.

Original Fourteenth-Century Window.

Modern Replica, by the late Sir Gilbert Scott.

A COMPARISON OF TWO WINDOWS IN GODALMING CHURCH.

lecture he would keep to the word "craftsman." The number was few of those who, having the power of design and composition, were artists, as compared with those who, skilful in the use of tools, could carry out work in an intelligent way, possessing the right to be called craftsmen.

A building, the author of which is inspired with poetic and noble ideas, will not have the effect upon us which our mediæval architecture has, if the craftsmen are not of a higher order than our machine craftsmen. In illustration of this point, the lecturer showed on the screen (1) a modern window by the late Sir Gilbert Scott, and (2) a fourteenth-century window, both from Godalming Church. The latter was obviously carried out by men who knew exactly what they were making, and who did not trouble to shape every curve with a pair of compasses, whereas the former was a pure copy. Can any one say there is no such thing as art when they compare these two windows? (See illustrations.)

The lecturer next showed two iron electric lamp-stands, in illustration of his comparisons. Concerning that on the left (see p. 119) he stated that it was made by Mr. Ernest Grimson, and was clearly a work of art, the craftsmanship being delightful.

The ideal craftsman will always have sufficient interest in his work to make him think out the details and treatment of what he is at work upon, so that, even in repeating his own work, he will be certain to make variations which may be so slight as to escape the notice of the ordinary observer; and this human quality will just give that something which will keep it alive, and turn the subject into a work of art. That is the keynote—"Keep it alive!" If the human mind can be seen in man's work, there need be no fear that the work will lack interest and life.

Next were shown two iron bedsteads (see p. 117), the one such as can be bought in a good English shop; the other an ordinary article of commerce in the Italian shops. The former was described as inoffensive, but giving no pleasure in the contemplation; the latter, however, gave interest and pleasure to the observer.

It is easier to work with our hands than with our heads. It is soothing to have some nice straightforward piece of work to do, but it should be the reward of mental work. The author remembered seeing at Merton Abbey William Morris at work upon a large drawing for a cretonne pattern. A fashionably dressed young man called to see Morris, who, during the interview, went on working. After a pause the young man said, "Can't you let all that spotting which you are doing be done by some draughtsman or clerk?" Morris burst out with the reply, "Do you think

that I am such a fool, after I have had all the grind of making this pattern and working it out, that I am going to let some other fool have the fun of spotting it?" To the lecturer's mind, it was quite wrong that one man should do all the thinking—that is, all the designing—whilst another, or others, should do all the making and have no thinking to do. In architecture, however, it is quite possible for one man to create a grand scheme, but to carry it out ought to be the work of many minds. Each craftsman ought to think as he works, and then noble buildings, such as were created in mediæval times, will result. It is astonishing how much interest—that is, humanity, or life—each workman can put into his work if he will take interest in it. If he will only *think*, he

A COMPARISON OF ENGLISH AND GREEK COINS.

will certainly be rewarded by great pleasure, and also by his work becoming art—that is, having life and giving pleasure to others. When a workman asks the lecturer a question about the work upon which they are engaged, the lecturer finds it an excellent formula to say, "Well, what do you think?" The good men respond, the bad ones do not, and show that they think you are asking for what they are not paid for.

The lecturer next showed slides of "Battens' wonderful altar-piece" at Kensal Rise, and of a well-known picture by Giorgione, and he did not think that Battens' picture suffered by the comparison.

To illustrate the unity of art and craft, Mr. Turner took two imaginary cases. In the first there is an able architect, who makes complete drawings of every detail, but has to trust to what the lecturer called machine craftsmen, whom he fails to inspire. In the second case there is a weak architect, with no great power of design. He does not give instruction in all details, but the true craftsmen understand their work, and the building, although having no great force of character from the one man, is nevertheless full of the feeling and characteristics of the many. Which of these two buildings will give the least pain or cause the most pleasure? The lecturer believed that the absence of

ALTAR PIECE BY BATTENS AT KENSAL RISE.

produce an ugly effect. Our craftsmen are apt to sacrifice everything to accuracy.

Referring to the subject of scale, or size, the lecturer said he felt sure that the sooner the architect, sculptor, and painter can get to work upon the actual piece of work he has to do, the better will be his chance of success. He gave instances of the way in which work suffers from being executed to a different size from that to which it is designed—of a design for a half-crown, which, when drawn to a size of about 6 ins. across, seemed a masterpiece, but lost all its merits in the reduction. A glance at the Greek coins (p. 118) would not leave much doubt that they were designed to their real size, and that the man who made the design made also the die.

After offering some excellent advice, based largely upon the thesis that "the perfect craftsman is the man who is craftsman and artist combined," the lecturer concluded by stating that he was very hopeful of the art work that is being done in this country. He was certain that since architects have brought themselves to break from the fetters of the styles and to use their common sense and natural instincts in designing, and have seen the necessity of honouring the craftsman, many delightful buildings have been erected, and of these he showed slides of a few.

TWO EXAMPLES OF MODERN LAMP STANDS.

good design would be felt far less than the absence of good craftsmanship.

But there is no reason why the conceiver of the whole building should not be in complete harmony with the craftsmen, and have the power of drawing out the best qualities of each craft, and yet of keeping all the crafts in their places and subservient to one another.

Having remarked that if a craftsman spaces out his work by eye, then, provided he is skilful, inaccuracies will not be obvious, and the whole work will gain in richness, the lecturer showed a slide of brickwork detail from Unstead Manor House, near Godalming, in which the work had, he thought, some bearing on the reference to spacing. In the slide (see illustration) brickwork of the fifteenth century as contrasted with some exceptionally good modern made brickwork. In both cases, old English bond—a row of stretchers and a row of headers alternately—was used. In the modern work the bond is rigorously regular. In the old work the pattern is frequently varied, with most pleasing results. The lecturer thought that such clauses in specifications as "The bricks are to be of uniform colour" and "the perpends are to be kept true" were wrong. To be pretty, the bricks should vary in colour as much as possible; and perpendicular joints that are exactly over one another

A COMPARISON OF ANCIENT AND MODERN BRICKWORK.

COLOUR AS APPLIED TO ARCHITECTURE.*

By Sir ALFRED EAST, A.R.A., Hon. A.R.I.B.A., and EDGAR WOOD, F.R.I.B.A.

The question of colour, as considered respectively by the painter and the architect, was dealt with quite typically by Sir Alfred East and Mr. Edgar Wood, at last week's meeting of the R.I.B.A. The two points of view were not difficult to reconcile, the two authors being in substantial agreement upon the main points that they put forward; and, of course, both concurred in deploring the comparative neglect of colour in modern architecture, and in advocating more sympathetic co-operation between painter and architect.

I.—BY SIR ALFRED EAST.

IN the past, when the conditions of transit were more difficult, the builder more frequently used the material he found close at hand, and often obtained a feeling of breadth and simplicity of colour which the modern builder, with his great facility of obtaining foreign materials, missed. The greater choice might tempt to unfortunate selection.

The art of retaining the peculiar quality of the material is of great importance. The architect who works within the limit marked out for him by local conditions and succeeds in a stronger artistic position than he who, having so large a choice, fails by being too generous

The Painter and the Architect.

The architect is, or should be, responsible for the absolute completion of a public building, and it is unfair to criticise him if some local authority assumes the responsibility of its decoration. It would be a great step on the way to obtain a perfect and completed scheme if the architect and the painter were brought into more intimate contact, and, by the interchange of ideas, to help each other to understand the peculiar claims of their individual crafts. During the last generation the architect has taken the sculptor more thoroughly into his confidence, and the author would like to see the same confidence extended to the painter. The place of the mural painting should have been considered by the architect in the creation of his plan, as much as that of the sculptor; neither is required for the actual structural qualities of the building, but both are a necessity for its perfect completeness.

Colour and Space.

The fitness of colour for decorative purpose is a question that has never been adjusted by any rule except that rule which is applied equally to the architect and sculptor. The first and most important is the sense of scale. The colour scheme may be satisfactory as a scheme, while the areas of the different colours employed are not in keeping with the scale of the building, where the architect may not have considered the space suitable for the work of the painter or sculptor in his design. The great problem of the application of colour to decoration has been solved in some instances with success; and in every case that success has been achieved by the perfect sympathy of those concerned in its production. The painter may spoil the work of the architect if there be not that sympathy. For instance, he may have his scale too large, the result being to diminish the dignity of the building. If, on the contrary, his scale be too small, the *raison d'être* of the painting is not secured. This sense of proportion is the first quality the painter has to establish.

Colour is entirely altered in its decorative quality by the shapes and sizes of its display. A certain arrangement of colour of certain sizes in conjunction may completely destroy the object of the architect, and yet the same series with a different arrangement may be perfectly satisfactory. Any colour expressed in angular forms must convey a different decorative sense from the same colour displayed by rounded forms. Herein lies a very subtle problem for the decorator, and one that has not hitherto been considered in its fullest significance.

The Question of Form.

The painter should not endanger the object he has in view by selecting such forms as are totally unfit to express a conjunction of colour, or to support the mental impression aroused by the architecture. He must not only discover what form will best express each individual colour, but be conscious of the difference of effect of these forms when brought into conjunction. One colour may be fine in quality alone, but brought into contact with others, may be discordant; not only that, but in their conjunction he may lose the peculiar value of an individual colour by the dominancy of another in juxtaposition.

The painter has to consider the masses and details of the building to be decorated; his decoration should be so sensitive that it should support not only the larger masses of the structure, but each detail by which the architect has himself embellished his structure. He must be as sensitive as the architect in sustaining the purpose of its being; he must not in any way destroy or warp such an object; he has no right to take away the knowledge that there is a surface on which his painting is superimposed, or remove by some optical illusion any structural quality of the building which is necessary for its support. All these things he has to consider, and, if he were a great decorator, he would consider these; but, if he be a victim of some local authority, who dictates to him what he shall do, or how he shall do it, then failure is certain.

The weight or intensity of colour should be just of that strength that helps the purpose. How often the opposite fact is revealed in the work that we see in some of the buildings of to-day!

II.—BY EDGAR WOOD, F.R.I.B.A.

Beautiful colour schemes in the majority of cases owe their origin to the East.

Colour is from the East.

A comparison between the Greek or Gothic use of colour as compared with that of the East resolves itself into a conflict between two opposing and antagonistic expressions, the expression of form and the appeal of colour, antagonistic because they represent two irreconcilable intentions. Colour is emotional, appealing to us by its emotional and sensuous

faculties; it comes to us before form, representing nothing in itself, dependent upon the emotional feeling it produces, and its rightful appeal to sensuous sensibility, whilst form is intellectual, and its appeal is the outcome of reason.

Treatment of Walls.

Turning to domestic work, one problem that all architects have to consider is the right or the best treatment of the walls that will assist the easel picture, or, as some would say, to minimise the defects of the same. It is often the problem of combining two distinct and conflicting principles. Scale effects the result naturally, but that is only a question of degree; the objectionable results of pictures and frames being out of proportion to their spaces and walls is only an accentuation of the difficulty.

What is Decoration?

Though the word "decoration" is frequently used, it is difficult, if not impossible, actually to define its limitation; it is, in consequence, employed in many and distinctly different ways, and certainly to many paintings of a very different treatment. It is generally accepted as embodying a simplifying of masses, of flatness of treatment, curtailing a tendency to absence of shadow, confinement to simple planes, careful composition in the proportionable filling of space, all combined with a certain architectural dignity or structural feeling by form and line, producing a mural feeling and a mural rest. The author could think of no stronger guidance to decorative effect than the influence upon the painter of the walls themselves, provided he will allow their unconscious appeal its full scope by executing the work upon the site.

The author advocated the judicious employment of drapery, rich or simple according to what it has to receive, never too rich as to overpower the picture to which it serves as a background, and never too simple as not to sustain the interest that the picture creates. The drapery itself also adds considerably to the look of comfort in a room; but in its selection, as in all treatments, it will always be remembered that it has not only to receive pictures, but, what is more important, it has also to serve as a background for the living and their dresses.

Surface Means Colour.

Marble is one of the most beautiful materials that Nature has provided for our service; but it never has by its inherent qualities alone competed with the best of man's contribution in its æsthetic appeal; it will never give the same convincing satisfaction that human effort has given us when he contributes the painted wall, and mosaic will even make a stronger appeal than marble because it permits of a greater proportion and display of the human faculty. A surface means colour, either of material applied, and therefore the treatment of it, remembered as quantity alone, has an importance that should justify the architect in his legitimate desire to control the decoration.

Colour and Hard Woods.

There is often a strong hesitation and reluctance on the part of the layman, sometimes shared by architects, to apply colour to hard woods, especially oak. Such a sentiment is human, but it fails to convince the colourist, who only sees his final aim curtailed in its crowning

* Read before the Royal Institute of British Architects on Monday, January 22.

ing result. The failure to realise that hard wood may be employed for durability alone, and therefore especially suitable and worthy of receiving skilled and careful colour treatment, has often deprived us of what would have otherwise been valuable additions to our colour possessions and our colour enjoyment.

The passing away of heraldry and of the necessitous use of armorial bearings has unfortunately deprived us of one useful and decorative source of colour—often the only *motif* and opportunity of relief which was given to the past—and it is difficult and often impossible to supply the place of that jewelled touch of rich colour which was yielded by its special purpose.

Greatly as architects should regret the disastrous separation of painters from architecture, there lies beyond it the cause of it, the endeavour on our part to neglect opportunities that may influence to bring back the painter to our assistance, and that the neglected art of great decoration shall be, so far as we are able, a neglected art no more, but shall continue to embellish our efforts of the future, as it has formerly jewelled and crowned others of the past.

DISCUSSION.

Mr. Gerald Moira, proposing a vote of thanks to the author, said he thought that landscape painting, when done in the manner of Chavannes, was the most beautiful decoration possible. The greatest difficulty experienced by the architect, of course, was the length of his client's purse. If they could only work together more economically, they might yet be able to show something of the George V. era that would be interesting in the future.

Mr. J. D. Crace, seconding the vote of thanks, said that most modern English painters were not sufficiently versed in architecture to understand what it was fighting for, and the architect could not be expected to have his building spoiled by misapplied painting. The decorative painter had the building for his space, and it remained for him to select the best colours to express the structural form. The old painters of the years between 1500 and 1600 never left a picture alone on the wall, but always supported it by accessories, and welded it into the building itself. A scheme of decoration should not be limited to pictures or to certain portions of a building; colour decoration should be distributed so as to form a structural part of the building and yet remain in itself a work of art.

Mr. H. H. Statham said that the basis of consideration of colour in architecture should have been what colour could be got from the materials of a building themselves. He knew that this was a much less intellectual side of the question, but one which, from the architect's point of view, was none the less important. At the present time there was a strong inclination most unjustly to vilify what was called the "easel picture." There was also a very confused idea of the word "decoration." There was, however, a distinction to be drawn between the decorative painting properly so called and the painting which depended upon itself. The finest picture in the National Gallery, Titian's "Bacchus and Ariadne," is not a decorative painting; it was a splendid piece of colour which would assert itself independently of its surroundings. If he had that picture, he would not care upon what wall it was hung. It was certainly undervaluing the

art of painting to say that it must harmonise with its surroundings. Painting had a claim for itself apart from the merely decorative; and so long as painting remained mural decoration alone, it would have to give up something of painting or else clash with architecture. The more they showed the effect of nature in landscape painting, the more they got away from architectural surroundings.

Mr. H. G. Ibberson, in the course of a humorous speech, professed not to understand the more mystical portion of Sir Alfred East's lecture, which associated curved forms with materialism and straight lines with spirituality. The room they were in, for instance, had an arched ceiling, while that in which the refreshments were served had a straight ceiling. Taking their president as typifying spirituality, they should surely change rooms, and serve the refreshments where they then were.

Sir Alfred East, in reply, maintained that it was really essential that painting and sculpture should be included in a dwelling house, and the architect should see that due provision was made for their reception. He disagreed with Mr. Wood's preference for "portables," such as tapestries and draperies, in the decoration of a room. Movability suggested life, and only the dead things remained permanent; that was why architecture was dead.

Mr. Edgar Wood, in reply, said he had been misunderstood if he was thought to have meant that there was no use for the easel picture. What he meant was that the highest ideal of decoration had never been brought about by the easel picture. In this respect, the finest picture galleries in the world would not bear comparison, in impressiveness of effect, with the Sistine Chapel. Some painters—Botticelli, for instance—were essentially mural in their style; but Murillo or Turner were not intended to go beyond the limits of their frames.

DETAILS, OLD & NEW.

The Old Bridge at Newbury.

Mr. R. W. Collier writes: "The series of 'Details, Old and New' is most interesting, and is so deserving of close study that one feels diffidence in questioning the correctness of the elevation of the bridge at Newbury in your issue of January 17th. Comparing this with the photo, the curvature of the cornice is surely not flat enough by a good deal, and, moreover, the number of balusters appears fewer in the elevation than in the photo, showing but two whole ones in the former and four in the latter. The difference considerably affects the character of the work."

[The greatest care is taken by the editor that "Details, Old and New" shall be absolutely accurate, so that any one copying them may realise a known effect, or, again, may vary them, at his own peril, to please his own ideas. It is unfortunate that the bridge at Newbury should prove an exception. What doubtless led to the errors, is the fact that the draughtsman who measured it is now in South Africa, and consequently his notes and measurements had to be plotted by someone else. The notes may have been imperfect, or perhaps confused. We thank our correspondent for writing to point out these mistakes.—Eds. A. and B. J.]

THE OLD COTTAGES AT GUILDFORD.

As a result of the expression of opinion at the recent meeting of the Surrey County Council, it is confidently expected that the Highways and Bridges Committee will recommend the county authority to release the Town Council of Guildford from their undertakings to widen Farnham Road, and so obviate the necessity of demolishing the picturesque old cottages of which illustrations have appeared in this journal—notably the dainty pencil sketch by Mr. Harold Falkner in last week's issue.

With respect to these cottages we have received the following note from Mr. P. M. Stratton, F.R.I.B.A.:—

"I wish to endorse all that Mr. Falkner so ably maintained as to the Guildford cottages in your last issue (January 24th). To an occasional visitor the town lives in the memory quite as much by the impression of these old cottages, as of Abbott's Hospital or the Guildhall. It is not as if your modern builder were likely to replace these walls and roof, steps and chimneys, with anything better. Until that day come, they should be left, a domestic homily on his raw taste, and should he ever see with his eyes and be converted to architecture, I for one hope he will continue to spare them."

THE WESLEYAN CHURCH HOUSE, WESTMINSTER.

In announcing that the Wesleyan Church House at Westminster will be opened in August next, a special contributor to the "Evening Standard" recalls a few data which, while most of them are already familiar to our readers, may be here usefully recapitulated.

The cost of the building is approximately £160,000.

The site is about one-third of the three acres formerly occupied by the old Royal Aquarium Buildings, and the architects, Messrs. Lanchester and Rickards, deemed it advisable to have the foundations 10 ft. deeper than those of the Aquarium.

The dome, which is now approaching completion, will be one of the landmarks of London. It is not so large as that on St. Paul's or the library of the British Museum, but it probably occupies third position. It is 90 ft. in diameter, and the measurement from the ground floor to the top is 220 ft.

It was originally intended to erect two towers over the front of the building, but as these would have interfered with the light and air rights of Westminster Hospital, that part of the scheme had to be abandoned. It is hoped to complete the plan at some future time if the hospital is removed to a more spacious site. The Church House is of Portland stone, which harmonises with the Government buildings that have recently been erected in the neighbourhood.

One of the chief internal features of the building is the large hall, capable of seating 2,600 persons. There is a gallery on three sides. The platform is arranged with a view to accommodating an orchestra of about 100 performers, and an exceptionally fine organ is being built. The large hall is on the first floor, which is reached by a wide staircase of polished grey marble. On the ground floor are two smaller halls, which will accommodate audiences of 600 and 200 respectively, together with a commodious library and committee-rooms. In the basement is a tea-room which will hold nearly a thousand people.

CORRESPONDENCE.

The Fire Resistance of "Eternit" Slates.
To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—There has recently been circulated anonymously (as though those responsible for it desired to avoid any possible legal consequences) a document which reflects very seriously and unjustly upon the qualities of the fire-resisting asbestos slates manufactured by us under the name of "Eternit"; and as the statements made in this circular are likely to do us much injury, we should be glad if you would allow us to make known the facts of the case through the medium of your columns.

The document in question is a translation from a report in German, issued by the Imperial and Royal Central Commission for Artistic and Historic Monuments, Vienna. It refers particularly to a fire which occurred at Castle Engelstein, near Gmund, the roofs of which were covered with *old process* "Eternit" slates. In this report, Conservator P. Benedikt Hammerl stated that blisters formed on the slates and exploded one after the other with a sound like that of a cannon, scattering thousands of fragments to a distance of 70 metres around the roof; and that in consequence of these explosions it was difficult for the firemen to carry out their work. The Central Commission urged that the Government technical experts should have their attention called to this implied defect in the material. (It may here be pointed out that *these particular slates were "old process" ones which had been manufactured by a method long since abandoned by us.* A different process has now been employed for many years, and the material has been subjected to very severe tests with most satisfactory results.)

The anonymous circulators of this misleading report have refrained from stating the actual facts about these particular slates, and the natural inference is that they were of "Eternit" brand as at present manufactured. This is untrue, and it is necessary that so damaging an insinuation should be at once contradicted.

First of all, it is not at all certain that the old slates behaved as the Conservator stated, for the commander of the Weitra County Fire Brigade, who attended the fire, reported that it was out of the question that anyone could see what actually happened to the roof, as the courtyard was filled with smoke. Minute particles, resembling little scales, were driven across

the yard by the strong wind which was blowing at the time, but none of the men, he stated, were in any way hampered or prevented from approaching the building by reason of these, and as a matter of fact, the brigades from Gross-Schoenau and Weitra were working hard on the particular wing where the slates were used. As a proof of the Conservator's confidence in "Eternit" as at present manufactured, it may be stated that he subsequently gave instructions for the re-roofing, with this material, of another building under his control.

The Imperial and Royal Ministry of Public Works instituted an enquiry into the report in question, and published a statement to the effect that the Imperial Commission had no right to express so derogatory a judgment concerning a roofing material which, in the sense of the building laws, had been accepted and recognised as a fire-resisting roof covering.

The Vienna County Council, by decree of December 17th, 1904, accepted "Eternit" slates, under the provisions of item 50 of the Vienna Building By-Laws, for use as a fire-resisting roofing material within the County Council area of Vienna, in conformity with certain conditions regulating the size of slates, lap, and minimum thickness.

In 1909 several fire tests were carried out under the direction of the commander of the Vienna County Council Fire Brigade and the control and supervision of experts. On that occasion favourable results were obtained with "Eternit" slates. Although one or two slates showed holes and cracks, the roof did not break away; the battening had burnt through, and the rafters had been badly charred, but the whole roof surface held together. Other materials were tested at the same time. Clay tiles and natural slates, laid on battens, crushed through as soon as the battens were burnt, and they immediately fell to the ground, the slates cracking and emitting a crashing noise.

It is on record that on the occasion of a test made on October 29th, 1911, in Voecklabruck, under the supervision of the Technical Commission of the Austrian Imperial Fire Brigades Union, the roof surface of the test building was covered with "Eternit" slates manufactured both under the old and the new process, the former flaking and cracking, and the latter remaining intact. "Eternit" was also tested with a certain natural variety of slate which, being played upon from one hydrant after the fire had been burning for ten minutes, completely cracked and opened up in all directions,

whereas the "Eternit" roof remained intact; only two slates showed hair cracks. Again, it is recorded in the report of the Royal Commission, on the occasion of the fire test made at Linz on October 30th, 1910, it was ascertained that only the "Eternit" roof and the galvanised iron section remained intact, while the sections covered with certain natural slates and other materials were completely destroyed. It is further pointed out that, while the statement of Conservator P. Benedikt Hammerl with respect to the "Eternit" slates made by the old process might be considered as in accordance with the facts, the particles of slate could only have been carried to a distance of 70 metres by the very strong wind which was blowing at the time of the fire. The storm-proof fixing of the slates, their having been subjected to fierce internal heat and sudden external water from the hose, would explain their being thrown farther than any other less solidly attached and heavy material.

Towards the end of this report, it is stated, very truly, that a material which can resist fire from within and without does not exist, and is not expected to by any building law. These building laws prescribe, it is said, that the roof should be covered with a fireproof material—that is to say, a material by means of which the spreading of fire from one roof to another may be prevented for the longest possible time; and "Eternit" had been found to answer all these requirements. The Commission's report concludes with what may be taken as an official apology for the wrong impression created by the report of the Commission for Artistic and Historic Monuments, and instructions are given for the State Surveyors to be enlightened as to the fire resistance of "Eternit."

We hope that the above statement may correct any misunderstanding that may have arisen in consequence of the anonymous circulation in this country of the report to which we have referred.

G. R. SPEAKER AND CO.

London, E.C.

[We are pleased to publish the above letter in vindication of "Eternit" slate. During recent years the use of fire-resisting compositions for the roofs and walls of buildings has greatly increased, the firm engaged in the manufacture of such material, in the form of tiles, slates, and slabs, having in several instances been compelled to extend their premises and to lay down new plant in order to cope with the constantly increasing demand. It is obvious therefore, that if the ne

After Test. "Eternit" Slates shown remaining intact.

A FIRE TEST WITH "EXIFPNIT" SLATES AND OTHER ROOF COVERINGS.

materials is to retain the confidence which it has already secured any criticisms concerning the fireproof qualities should be investigated as soon as they are made, and any misstatements at once corrected.
—EDITORS, ARCHITECTS' AND BUILDERS' JOURNAL.]

Skeleton Frame Buildings.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—We shall be glad if you will kindly allow us the use of your columns in order to make an announcement that will, we feel sure, be of considerable interest to architects and others concerned in steel-frame buildings.

It is enacted in Section 22 of the London Building Act Amendment Act of 1909 (9 Edward VII. cap cxxx.), that, when it is proposed to erect a skeleton frame building, copies of all the plans, sections, and calculations in detail shall be deposited with the district surveyor.

As it will manifestly be convenient alike to the architect, engineer, and district surveyor that these drawings and calculations shall be submitted upon a uniform basis, thus greatly reducing the labour of making and checking the calculations, the District Surveyors' Association (Incorporated) have, with the co-operation of the Science Standing Committee of the Royal Institute of British Architects and others, drawn up a scheme to be adopted by persons depositing plans, sections, and calculations with the district surveyor.

This scheme is now completed, and copies may be obtained of the Association's publishers. It provides for a uniform system of nomenclature, the adoption of uniform symbols and uniform calculation sheets for pillars, beams, and foundations. It also contains the formulæ necessary for making the calculations, a schedule of weights of materials, and a number of tables of value.

(Signed) WILFRED J. HARDCASTLE,
President,

BERNARD DICKSEE,

Hon. Secretary,

District Surveyors' Association (Incorporated), 9, Conduit Street, W.

Government Architectural Assistants.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Adverting to the answer given in the House of Commons by Mr. Dudley Ward, as representing the First Commissioner, on November 24th last, when promising to consider establishment for the "Architectural Assistant" class, I may be allowed to point out that he spoke of the consequent sacrifice of income demanded by the regulations "when becoming established to pay for pensions, etc."; it should be understood that the "Assistant Architects" Civil Service Examination (the present unsatisfactory method of recruiting for the establishment) was altered from an open to a nominated one, and restricted to "draughtsmen" in the Department in 1902, and that this was to be regarded as an opportunity expressly intended in future as some recognition of the long and efficient services of the "Senior Draughtsmen" class (since 1907 termed "Architectural Assistants"), who were in receipt of £165, and upwards, per annum, and the salary was fixed, for those candidates who obtained established posts, at £150 per annum (subsequently £200); and so the Treasury rule of "sacrifice of income,"

to the extent of £15 or more, would have been met.

But as these senior men had already been searchingly examined for years past by their Board in carrying out their daily duties, it seems they naturally expected establishment without further test, and did not respond to the invitation to be nominated, and so, for the past ten years, this Treasury rule has been ignored by the Department, and Junior Draughtsmen nominated, mostly with short service (some only just attained the minimum age of 23, and some with only six months' service), and the successful ones have thus had their salaries *increased*, not diminished, to the extent of some £70 to £120 per annum, plus their pensions, etc.

Thus the anomalous feature obtains of a junior leaving one week-end at the rate of 30s., and returning the following week at £4, plus "extras," to do the same work for the same employer, and all by the magic wand of the Civil Service Commissioners! *Ipso facto*, he was either underpaid before, or overpaid after.

But the "Architectural Assistant" class look to their First Commissioner for justice when placing them upon the Established list by considering this past injustice, and their long professional service with wholly inadequate pay, as deserving of an increase, rather than a sacrifice, of their incomes.

ARCHITECT.

R.I.B.A. PRIZES AND STUDENTSHIPS, 1912.

The designs and drawings submitted for the Institute prizes and studentships are now on exhibition in the R.I.B.A. Galleries (9, Conduit Street, W.). The chief results were announced in last week's issue, p. 85. The official list of awards is now given:—

THE ROYAL INSTITUTE SILVER MEDALS.

(i.) *The Essay Medal and Twenty-five Guineas.*

Twelve essays on "The Principles to be observed in Designing and Laying out Towns, treated from the Architectural Standpoint," were received for the Silver medal. The Council have awarded the medal and twenty-five guineas to the author of the essay submitted under the motto "Redundancy" [T. Harold Hughes].

(ii.) *The Measured Drawings Medal and £10 10s.*

Five sets of drawings were sent in. The Council award the medal and ten guineas to the author of the drawings submitted under the motto "Zeta" by Arthur Edwin Maxwell, who submitted six strainers showing Compton Wynyates; and certificates of hon. mention to the authors of the drawings submitted under the mottoes "Shopeinshouedes" by A. B. Allen (five strainers showing the Octagon, Ely Cathedral), and Walter M. Keesey (six strainers, Church of Santo Spirito, Florence).

THE TRAVELLING STUDENTSHIPS.

(i.) *The Soane Medallion and £100.*

Thirteen designs for a Guildhall were submitted. The Council regret that they are unable to award the Soane Medallion, but they award a certificate of hon. mention and the sum of fifty pounds each to the authors of the designs bearing the mottoes "Circle City" [William Friskin] and "Antæ" [Piet de Jong], on the condition that the authors make a three months' tour on the Continent in accordance with the conditions attached to the prize. They also award certificates of

hon. mention to the authors of the designs bearing the device and motto respectively of "Sailing Ship" [C. A. Harding] and "Vista" [Bertram Lisle].

(ii.) *The Owen Jones Studentship and £100.*

Two applications and drawings were received. The Council have awarded the certificate and (subject to the specified conditions) the sum of one hundred pounds to Mr. Noel H. Leaver.

(iii.) *The Pugin Studentship and £40.*

Nine applications were received for the Pugin Studentship. The Council have awarded the medal and (subject to the specified conditions) the sum of forty pounds to Mr. James Macgregor, and certificates of hon. mention to the following, who are bracketed as equal:—Mr. C. Peake Anderson, Mr. W. J. P. Jones, Mr. J. R. Leathart, and Mr. R. Norman Mackellar.

(iv.) *The Godwin Medal and £65.*

Two applications were received for the Godwin Bursary. The Council have awarded the medal and (subject to the specified conditions) the sum of sixty-five pounds to Mr. Geoffrey Lucas.

(v.) *The Tite Certificate and £30.*

Eleven designs for the Central Court-yard of a Royal Exchange covered with a roof were submitted. The Council have awarded the Tite certificate and (subject to the specified conditions) £30 to the author of the design bearing the device "Red Lion" [Louis de Soissons], and a certificate of hon. mention to the author of the design bearing the motto "The Circle" [Thomas H. Chalkley].

THE ARTHUR CATES PRIZE: FORTY GUINEAS.

Three applications were received for the Arthur Cates Prize. The Council have awarded the prize to Mr. James Bertie Francis Cowper.

PRIZES FOR DESIGN AND CONSTRUCTION.

The Grissell Gold Medal and £10 10s.

Four designs for an Isolated Exhibition Building were submitted. The Council have awarded the medal and ten guineas to the author of the design bearing the motto "M.C.M.XII" [Thomas Braddock].

THE ASHPITEL PRIZE 1911.

The Council have, on the recommendation of the Board of Architectural Education, awarded the Ashpitol Prize (which is a prize of books, value £10, awarded to the candidate who has most highly distinguished himself amongst the candidates in the final examinations of the year) to Mr. Philip Dalton Hepworth, Probationer 1907, Student 1910, who passed the final examination, November, 1911.

THE TRAVELLING STUDENTS' WORK.

Pugin Student 1911.—The Council have approved the drawings executed by Mr. James Bertie Francis Cowper, Pugin Student 1911, who travelled in Northamptonshire, Rutlandshire, Lincolnshire, and part of Norfolk.

Panels in the Royal Exchange.

Offers have been made to the Gresham Committee to fill two of the vacant panels in the Royal Exchange with frescoes or paintings depicting subjects connected with the Coronation and with the opening of the Australian Commonwealth Parliament. For the moment the gifts have not been accepted, probably because it has been felt that the inclusion of these modern and extraneous subjects would destroy or disturb the chronological sequence of the scheme for filling the panels. Possibly, as in a previous instance, the offer may be transferred to the Guildhall Art Gallery.

NEWS ITEMS.

M. Daumet's Bequest.

The late M. Daumet has left by will to the Académie des Beaux-Arts an annuity of 4,500 francs, to be applied in augmenting the pensions of aged architects.

Professional Announcement.

Mr. H. Bedford Tylor, for 16 years architect and surveyor on the Bournville Estate, is now in practice on his own account at 20, Linden Road, Bournville, and c.o. Messrs. Mayhew and Darling, solicitors, 38, Waterloo Street, Birmingham.

Parish Church, Carrington.

Twelve architects were selected to compete in the competition for the proposed new church of St. John the Evangelist, Carrington, Notts, which is estimated to cost £9,000. The assessor is Mr. Edward S. Prior, F.S.A., F.R.I.B.A., and the date for sending in designs was January 22nd.

Sheffield's King Edward Memorial.

Fitzalan Square is to be the site for the King Edward VII. statue which, together with the cripples' home, will be Sheffield's memorial to the late King Edward. The report on which the decision was based was prepared by Mr. Alfred Drury (the sculptor), Mr. W. J. Hale (architect), and Mr. F. E. P. Edwards (the city architect).

New Street Station, Birmingham.

The London and North-Western Railway Company is about to expend upwards of £100,000 on improvements at New Street Station, Birmingham. It is more than twenty years since the latest extension of the station took place. The alterations will result in a much loftier and more imposing facade to the station. The lighting is to be done on one side by high-pressure gas and on the other by electricity.

Largs Battle Memorial.

The committee of subscribers to the fund for erecting a memorial of the battle of Largs have chosen the design submitted by Mr. J. S. Kay, architect, Wellington Street, Glasgow. It was arranged that the architect should be communicated with in regard to details, the committee desiring that the memorial may be as nearly as possible assimilated to the ancient round towers of Abernethy or Brechin. A sum of about £318 is available for the erection of the memorial.

Two New Town Planning Schemes.

The Local Government Board have given authority for the preparation of two further town-planning schemes under the Housing, Town Planning, etc., Act, 1909. The schemes are to be prepared by the Corporation of Liverpool and the Urban District Council of Hanwell. In the case of Liverpool the scheme is to apply to about 88 acres of land, comprising Oakhill Park and land adjoining thereto, situate near the eastern boundary of the city. In the case of Hanwell the scheme is to extend to an area of about 198 acres.

Business Change.

Notice is given that the partnership previously subsisting between Mr. James

Taylor Duthie and Mr. Frederick Dobson, carrying on business as joiners and builders at 14 to 24, Cornus Street, Liverpool, under the style of "Duthie and Dobson," has been dissolved by mutual consent as and from January 13th, 1912. All debts due to and owing by the said late firm will be received and paid by James Taylor Duthie, who will continue to carry on the business in the name of "J. Duthie and Son."

Ventilation and Warming Installations.

The Church of England Schools, Padicham, are being ventilated by means of Shorland's patent exhaust roof ventilators and special inlet ventilators, supplied by Messrs. E. H. Shorland and Brother, Ltd., of Failsworth, Manchester.

The Dutton Isolation Hospital, near Warrington, is being supplied with Shorland's double-fronted patent Manchester stoves and Manchester grates.

Christian Science Church, Edinburgh.

The new church which has been erected in Inverleith Terrace by the Edinburgh Christian Scientists, and which was recently dedicated, is stated to have cost about £11,200. It is designed in the manner of the late mediæval buildings of Scotland, and is seated for 636 persons, including 118 in the gallery. Mr. Ramsay Traquair, Edinburgh, was the architect.

Small Greenhouses.

A recent addition to the admirable series of "One and All Garden Books," edited by Mr. Edward Owen Greening, F.R.H.S., is on "Small Greenhouses," by T. W. Sanders, F.L.S. (price one penny, London Agricultural and Horticultural Association, Ltd., 92, Long Acre, W.C.). It bears out the claim for it in the editor's foreword that it is "clear, practical, and comprehensive." The author advocates the abandonment of formalism in the greenhouse as in the garden, and the introduction of "natural and truly artistic effects." Various forms of greenhouses are illustrated, and heating apparatus receives special attention.

Dearer Coal—Cheaper Gas.

The announcement that, coincident with a serious rise in the price of coal, the price of gas has again been reduced 1d. per 1,000 cu. ft. by the Gas Light and Coke Company, comes as a pleasant surprise. This reduction—following upon a similar lowering of price each January for four successive years—brings the charge down to the even half-crown. With the knowledge that gas is down to 2s. 6d. per 1,000 cubic feet, and that the Gas Light and Coke Company hold good stocks of coal, the consumers in their district can regard the coal merchants' announcements of higher prices and the prospect of a temporary stoppage in coal supplies with a decidedly easier mind than before.

Extensive Steel Roofing.

For a large new garage that is to be erected in West London, Messrs. Peirson and Co., of 17 and 18, St. Dunstan's Hill, Great Tower Street, E.C., have received an order for steel roofing to cover an area of about two acres. This roofing is constructed on a new principle, giving large clear spans uninterrupted by interior

supports of any kind; and the system is said to admit of exceptionally light and cheap construction. We understand that the whole order will be fulfilled within the short period of thirteen weeks, and that Messrs. Peirson and Co. will be glad to furnish architects with particulars and designs for any similar work.

Glasgow Technical College.

At a meeting of the Technical College Architectural Craftsmen's Society, Glasgow, on January 20th, Mr. James S. Boyd in the chair, a lecture was given by Mr. James McKissack on "Rothenburg-on-the-Tauber and other Bavarian Towns." The lecturer gave a general description of Bavaria, and described the situations and methods of reaching the various towns. A great number of excellent slides were shown, proving the claim of Rothenburg to be called a "city of dreams and fairy hills," rich in architectural and historic associations. The lecturer also gave a short description of other interesting towns, including Harburg, Dinkelsbüll, etc.

Carlton Hotel Improvements.

The fire which attacked the Carlton Hotel last August, when all but 21 out of 300 rooms were damaged by water, has, in the result, given the management the opportunity to introduce various improvements at a cost of £100,000. Wood has been abolished from the hotel wherever possible, and this change is most notable in the staircase built of white and grey-green marble from the Mitylene quarries. The suites of rooms have been fitted with sound-proof doors, ensuring absolute quiet, and more than half of them have been provided with private bathrooms. The bedrooms are provided with telephones and steam-heating apparatus. The newest feature is a system of coloured lights for summoning different servants. These lights are reproduced at each junction of the corridors, and again in a central office where they are noted by an attendant, who calls attention to the fact if the call is not answered within a reasonable time. This apparatus, which is said to be the first of its kind installed in England, has 80 miles of wire and 10,000 connections.

Haslemere Garden Suburb.

A start will shortly be made on the building of a first batch of cottages in the Haslemere Garden Suburb, a scheme which is being carried out by the Haslemere Tenants, Limited, the chairman of which is Mr. Aneurin Williams. In all nearly 60 houses will be erected, and the first 21 will be of three types, costing £140, £165 and £220 each. The £140 cottages will consist of a living-room and scullery on the ground floor and two bedrooms up stairs. These are intended especially for people who do not want a large house—old people and couples without families—a class which the promoters consider frequently forgotten in schemes for ideal cottages. The houses at £165 will have three bedrooms, and those at £220 will have the addition of a parlour and a bathroom. On the completion of 20 cottages the company will arrange for the building of the other portion of the suburb. As the houses will have good-sized gardens the tenders are lower than was originally expected, with the result that the rent will be lower than was anticipated.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

 A second edition has just been issued of the *Concrete Manual*. Very useful volume on "The Everyday Uses of Portland Cement," published by the Associated Portland Cement Manufacturers (1900), Ltd., at Portland House, Lloyd's Avenue, E.C., price 1s. 6d. net or 2s. 6d. net, according to the binding. Of the first edition, which was issued some three years ago, it was possible to say that it was a comprehensive *vademecum* for the cement user; and this praise may be repeated with emphasis for the new edition, which has been subjected to thorough revision, with the addition of much new matter, including a glossary of technical terms and an index. The very important subject of reinforced concrete is dealt with at considerable length, some thirty or more pages giving all the details that are likely to be required by any one who is not a trained expert in this system of construction, while even the specialist will be glad to avail himself of so admirably succinct a summary of principles and practice.

A Fundamental Principle.

The clearness of ex- position that distinguishes the volume throughout is well exemplified in this explanation of the fundamental principle of reinforced concrete construction: "The fundamental principle underlying the various applications of reinforced concrete is, that whereas steel is extremely strong in tension, concrete is strong in compression but comparatively weak in tension. That is to say, concrete will resist an enormous crushing load, but it is brittle and will break across if loaded as a beam. Comparatively, concrete is cheap, whereas steel is dear, and is moreover subject to corrosion if it be unprotected. However, it has been found that the two materials can be used in combination to their mutual benefit and with great economy." The old familiar data could hardly have been more tersely or more clearly stated, and the passage is characteristic of the lucidity observable in marked degree throughout the volume. Folding diagrams for calculating slabs and beams are included, and the methods of calculation are fully illustrated both by diagrams and by means of formulae. No more successful attempt to initiate the beginner into the not very recondite mysteries of reinforced concrete construction has ever come under our notice, and upon that account alone the book would be valuable.

The General Utility of Portland Cement.

It has many other claims to attention. Portland cement, its physical properties, its manufacture, and its innumerable applications, are described or indicated in more or less detail. The tools, machinery, and accessories employed in applying it are fully illustrated, and there are a dozen photographic representations of the various surfaces produced by different mixtures of concrete. Finally, in the "examples of the uses of concrete," common and uncommon, there is a long

and an exceptionally interesting list of structures of extraordinarily miscellaneous description; the inference being that almost anything can be satisfactorily constructed of that universally applicable material. It is, therefore, the less surprising to be told, on the authority of this interesting and valuable manual, that the world's annual output of Portland cement may be estimated at more than twenty million tons.

"Artistic Treatment" Again.

As Professor Beresford Pite's paper on "The Artistic Treatment of Concrete" was read at the summer meeting of the Concrete Institute, and as the adjourned discussion on it is yet to be resumed, there can be no complaint that the matter is being hustled, or that members have not been given time to turn the subject over in their minds. Some, indeed, will probably regret that they have had time enough to forget all about it. Nevertheless, it is to be hoped that architects, in particular, are giving the matter its due share of attention, and that on the resumption of the discussion they will be present in full force to give expression to their views on what is no doubt an eminently debatable subject. It is, indeed, a subject on which most of us are keeping an open mind, and, truth to tell, are not over-anxious for conviction either one way or another. No matter, therefore, to which side, if any, the balance of opinion in this discussion may happen to lean, there will always be those who, on the one hand, hanker after decorative effect in every material, and in all its adaptations, and those who, on the other hand, stand out for austere simplicity; and the greater or less degree of success of either of these parties of extremists will depend on the extent to which they can capture the neutrals, and thus neutralise each other's excesses. It is probably the midway men who will control and give character to the current or established practice that will ultimately emerge from the ordeal of controversy and experiment.

Extremists and the Medium.

Those who moderate on the uncompromising views of the extremists, and who see no reason should not be redeemed from absolute baldness, and, again, deprecate the equally undesirability of excess of ornamentation, are making a careful study of the possibilities of the material. Many articles and a few books have resulted from their enquiries and their essays in practice. An interesting and a suggestive book on the subject is "Ornamental Cement Work," by Mr. Oliver Wheatley, which has just been issued, price 5s., by Messrs. Scott, Greenwood and Son, of 8, Broadway, Ludgate Hill, E.C. Mr. Wheatley makes out a very good case for the decorative treatment of Portland cement. He claims that it affords the artist facilities that are only, if at all, inferior to those offered by canvas or paper, and superior to modelling in clay or wax, because these

are only preliminary processes, whereas the modelling of concrete is final and permanent, thus giving free play to the personality of the artist, allowing him unequalled opportunities for directly impressing his individuality on the work. This very facility is no doubt in a sense prejudicial to acceptance of the work. The average beholder, at any rate, who thinks anything about it at all, does not like to feel that the artist has had a very soft job, but, on the contrary, likes to admire the manner in which difficulties have been overcome, as when, as Virgil sings, "Others shall mould the brass with livelier grace, and from the marble draw the living face." But probably the average beholder satisfies himself with the effect, and never troubles himself in the least as to how it was obtained, nor even as to whether the material is cement or stone, or whether the ornamentation has been modelled, moulded, or chiselled.

Art and the Cement Worker.

He it is, however, this average sensual man, who, hating austerity, demands decorative treatment independently of the material used; and the crucial question is whether this demand can be legitimately met in the case of reinforced concrete buildings. This, however, is rather beyond the scope of Mr. Wheatley's book, which deals mainly with the ways and means of producing in cement "daintily detailed doorways, gateposts, balustrades, name tablets, garden pedestals and vases, fountains and rock gardens, basins in conservatories for gold-fish, and many other pleasing objects." Much of the ornamentation shown in the book is nevertheless adaptable to larger and more purely constructive work, to which, with here and there some slight modification, the methods of production are applicable. The author realises that "cement work must be pursued as an art. . . . To obtain the best results, the cement worker must be a person of education and ample means of reference to historic art. His work must reflect judgment and taste, which only come of training and experience. Unless this is so the very facilities of this material render it a danger for abuse." In another place he suggests that "we may take a doorway in the purest style of Classic, Renaissance, or Gothic art, and faithfully produce it with all the interest of carved stone. Or we may break new ground. . . . It may be mere prejudice, but we cannot bring ourselves to admit that "all the interest of carved stone" is possible in cement, which, consequently, as Mr. Wheatley elsewhere admits, requires special treatment in conformity with its special characteristics. The close imitation of stonework is therefore to be deprecated. If this were not so, there would be no problem to solve. As it is, we have still to find out the decorative capabilities of cement, and the best and truest methods of developing them. Mr. Wheatley's book, however, though it may not throw very much light on the aesthetic treatment of buildings, is strong both on the technical and on the artistic side, the instructions being practical and sufficient, while the advice as to

the choice and arrangement of ornaments is on the whole sound and judicious. As a guide to the minor operations already enumerated—the production of garden ornaments, and so forth—it should be invaluable. There are eighty-one well-chosen illustrations dispersed throughout the book.

STEEL-FRAME FACTORY, WITTON, BIRMINGHAM

This factory at Witton, Birmingham, covers an area of 47,000 superficial feet, and, while being an example of the simplest and cheapest possible form of steel-frame structure, is yet designed of efficient strength, with the usual safety margins, to carry floor loads of 2 cwt. per foot super.

This design permits of walls of a maximum thickness of 9 in. being used, thus economising space and reducing the brickwork cost to the lowest possible point. Nevertheless, all joints and connections are carefully designed to sustain their respective loads, and at the same time resist any unequal stresses due to wind effect, or any slight disturbance of foundations.

The steel stanchions, which are spaced at about 13 ft. 6 in. centres, are throughout made up of joist sections with rolled flats riveted on their flanges, and resting directly upon the concrete foundations; the bases being of sufficient size to spread the load, thus saving the cost of stone bases or grillages.

The main girders are also built up of joist sections with flange plates as required, and the bars for reinforcement

of the concrete floors are of a small joist section.

The aggregate for the concrete was 3 parts of good hard furnace clinker, 1 part of sharp sand, to one of Portland cement, the Associated Portland Cement Co.'s Ferrocrete brand. No treatment is required on the soffits of the floors, care being taken to secure a fair surface ready for distemping.

The whole of the steel stanchions and girders, where not embedded in the floors, are encased with 2 in. thick of fire-resisting Gypo non-conducting cement, finished right off with a perfectly smooth surface.

None of the floors exceeded 6 in. thickness, and owing to the care in the selection of the aggregate, no expansion or contraction has been recorded.

The accompanying illustrations show a scheme including large factory and warehouse blocks. The larger, of four storeys, is devoted to the warehouses, packing and carding rooms, and the smaller block of three storeys comprises the manufactory in which stamping, gilding, and finishing processes are carried out.

The keynote adopted in designing the whole scheme is the erection of a steel skeleton with an outer casing of brickwork merely employed as a facing.

It will be noticed from the plan that all the floors are carried on one row of stanchions in each block, thereby giving the maximum amount of floor space.

The whole of the outside stanchions are encased by a 4½ in. skin of brickwork, and the intervening space is filled in with fine concrete, thus making a pier of 1 ft. 10½ in. by 1 ft. 6 in., 9 in. walls being bonded in up the sill level of the windows. It will be seen that by this form of construction the minimum of pier is used,

thereby giving the maximum of window area. It is believed that this is the only four-storey building in the country with 9 in. brick walls for the full height.

The warehouse block is 120 ft. by 46 ft. and the factory 140 ft. by 60 ft., thus giving a total floor area for the works of over 47,000 sq. ft.; the height of each department from floor to ceiling is 10 ft. 6 in.

In some parts of the building wooden floors were necessary, so 3 in. by 2 in. joists on the splay were bedded into the concrete, and to these 4½ in. floor boards, 1½ in. thick, were spiked. These floors are absolutely sound-proof. The remainder of the concrete floors are covered with 2 in. of granolithic.

An electric lift connects the two blocks, also serving the mezzanine floor, comprising two private offices, the windows of which are so arranged as to command views of four floors; and being placed in the centre of the works give perfect supervision.

The whole of the steelwork has been designed sufficiently strong enough to admit of an extra storey being built at any time, without any addition to the existing steelwork.

The architect is Mr. Burkett J. Emery, of Birmingham and London. The roofs are concrete flats covered with two layers of Lithenite, supplied and laid by Messrs Engert and Rolte, Ltd., of London. The steelwork, 300 tons, and concrete floors were carried out by Messrs. A. D. Dawnay and Sons, Ltd., of London and Cardiff. The whole building only took seven months to complete. The building contractors were Messrs. W. B. and H. Archer, of Handsworth, Birmingham.

The cost of the building worked out at the low price of under 3d. per ft. cube, lift and heating system being included.

WAREHOUSE AND FACTORY AT WITTON, BIRMINGHAM, IN COURSE OF ERECTION.

Supplement to THE ARCHITECTS' AND BUILDERS' JOURNAL, Wednesday, January 31st, 1912.

TITE PRIZE DESIGN. BY LOUIS DE SOISSONS.

TITE PRIZE DESIGN. BY LOUIS DE SOISSONS.

GENERAL VIEW OF FACTORY.

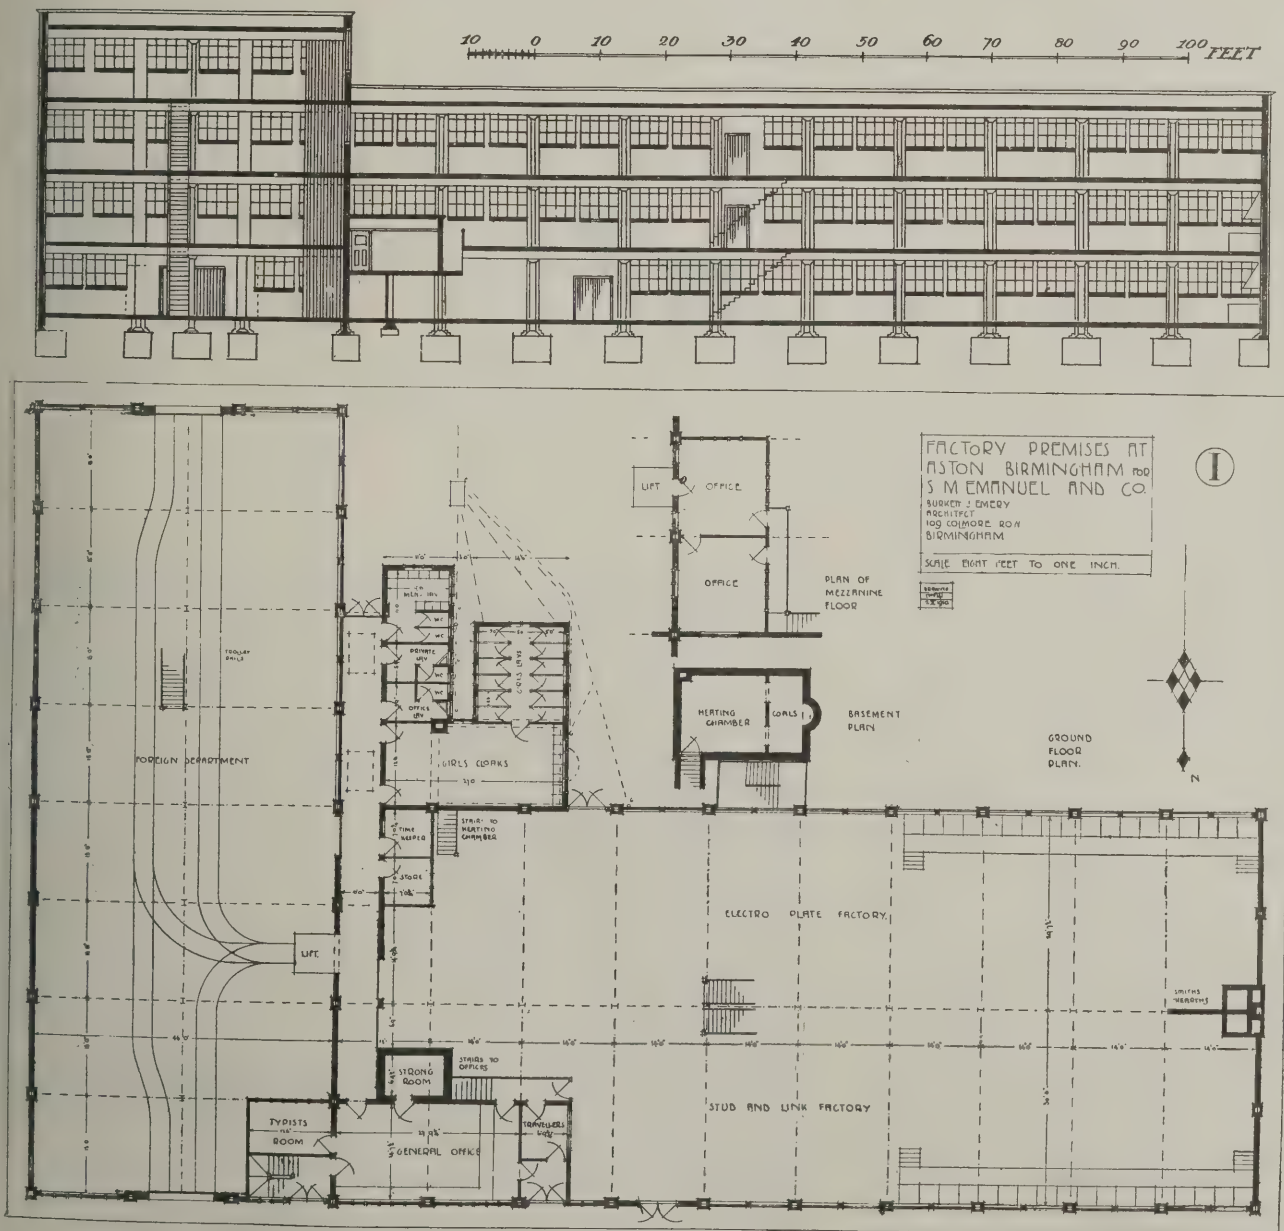

THE CONSISTENCY OF CONCRETE.

An interim report of the Reinforced Concrete Practice Standing Committee of the Concrete Institute, relating to the consistency of concrete, has been drawn up, and was presented at the twenty-second ordinary general meeting of the Institute.

A circular letter of inquiry on the subject had been addressed to the members, in which it was suggested that a specification as drafted would be of service, pending experiments and tests that ought to be made to determine the exact proportion of water to be used in concrete in order to obtain the best mixture. This specification, as now slightly modified by the Committee, is as follows:—

Consistency of Concrete.—For mass concrete the quantity of water added to the other constituents shall be sufficient to make a plastic mixture which, after thorough ramming, will quiver like a jelly.

For reinforced concrete the quantity of water added to the other constituents shall be such that the plastic mixture is capable of being rammed into all parts of the moulds and between the bars of the reinforcement.

FACTORY AT WITTON, BIRMINGHAM: VIEW OF COMPLETED BUILDING FROM THE REAR.
BURKETT J. EMERY, ARCHITECT.

STRESSES IN REINFORCED CONCRETE COLUMNS.

Note.—In dry or hot weather the quantity of water shall be increased in order to allow for evaporation.

Fifty-eight replies were received, and they were carefully considered by the Reinforced Concrete Practice Standing Committee, who have come to the following conclusions:—

(1) It is inadvisable to lay down any definite rule as to the percentage of water to be used in mixing concrete, owing to the varying conditions which obtain. The proposed specification is difficult to improve upon, and seems to meet with general agreement.

(2) The strength of concrete apart from any reinforcement increases as the amount of water used in mixing is decreased, this being more particularly the case during the earlier stages of the maturing of the concrete. Eventually the wetter of two mixtures will approach more nearly to the drier in strength.

(3) In reinforced concrete, particularly in such portions as may contain a large amount of reinforcing bars or the like placed closely together, it is essential that the concrete should be sufficiently wet to pass between the reinforcing bars, and to surround thoroughly every portion of the steel. This should be ensured even at the expense of having the concrete wetter than would otherwise be desirable.

Where the reinforcement is not very closely spaced it is unnecessary for the concrete to be so wet.

(4) Other conditions being the same, the drier the concrete the more quickly will it set and mature. This is of importance when there is any danger of green concrete being attacked by frost.

(5) The wetter the concrete the greater is the tendency to contract during the process of setting and maturing. Appreciable contraction may sometimes continue for a period of several years.

(6) The Committee is divided as to the advisability of determining by some means of mechanical test the exact degree of "wetness" or consistency of concrete after mixing. If some scale of consistency were adopted, it would be possible to specify that concrete for any particular portion of the work should be of such and such a consistency, after mixing. This would not, of course be at all the same as specifying that any particular amount of water should be used in mixing such concrete, owing to differences of atmospheric temperature, aggregate, etc.

The advocates of the institution of some such scale of consistency are of opinion that the Concrete Institute should carry out tests on the subject.

In carrying out the experiments described in his paper on "The Direct Experimental Determination of the Stresses in the Steel and in the Concrete of Reinforced-Concrete Columns," which was read before the Institution of Civil Engineers, Mr. W. C. Popplewell, Associate, sought for a satisfactory method of measuring the shortening of the steel bars and the simultaneous shortening of the adjacent concrete under the loads applied to reinforced columns. From these measurements, if they were reliable, he thought it would be possible to calculate the stresses in the steel and concrete, when the elastic moduli for the two materials were known. It was also thought that measurements made in this way would be the means of revealing any movement of the steel relatively to the concrete. The main experiments were carried out on five columns 6 in. square, each reinforced by four round-steel bars $\frac{3}{4}$ in. diameter. Loads were applied in a testing-machine, and corresponding shortenings of the steel and concrete were measured by means of Martens extenso-

meters. For the steel these were applied to the ends of pairs of pins projecting from the reinforcing bars through holes in the concrete, and for the concrete they were applied to the surface as near as possible to the steel. From the results of the experiments, four pairs of curves were plotted for each column, one pair for each of the bars. These curves are given in full detail in the paper, and their peculiarities are discussed.

Besides the main experiments, others were carried out to compare the effect of loading when the load was uniformly distributed over the end of the column and when it was applied in the centre. This enabled a comparison to be made between the effect of having the load transmitted directly to the ends of the bars, and having it communicated to the bars through the holding grip of the concrete. The result showed practically no difference. The experiments to find out the value of the modulus for the steel and the concrete yielded values respectively of 30,200,000 and 1,535,000 lbs. per square inch.

A further set of experiments carried out to determine the intensity of the frictional grip of the concrete on the steel resulted

FACTORY AT WITTON, BIRMINGHAM: INTERIOR VIEW.

in values ranging from 300 to 600 lb. per square inch of bar surface, to cause slipping. The stresses in the steel and concrete, calculated for a working-load of $13\frac{1}{2}$ tons which the columns were designed to carry, were found to be, respectively, 437 lb. and 8,650 lb. per square inch. This gives a load on each bar of 1.7 ton, and, comparing this with the load required to push one of the bars through the concrete, as found from the experiments on frictional grip, it is evident that from this point of view there could not have been any slipping of the steel in the concrete.

The author considers that the manner in which the strain measurements were made proved very satisfactory, and that the method might be extended to other cases. A careful inspection of the resultant plotted diagrams appears to show that, when all the effects of eccentric loading have been eliminated, there is no evidence to indicate that slipping took place; and it is evident that in columns of this kind made up with plain smooth bars the two materials behave like one so far as their strain effects are concerned.

COMPOSITE COLUMNS OF CONCRETE AND STEEL.

Mr. William Hubert Burr, M.Inst.C.E., in a paper read before the Institution of Civil Engineers, described a series of tests which he had made on the effect of a concrete filling on increasing the carrying-capacity of a steel column, a subject that had never been sufficiently investigated. The columns tested consisted first of two types of built-up columns of plain steel, and secondly of exactly similar steel members filled with concrete. The reinforced-concrete columns were filled with 1 : 2 : 4 concrete, and were tested at 3 months. The steelwork consisted in one case of four vertical steel angle-bars arranged as the four corners of a square and braced together with lattice bars to form a square column $6\frac{1}{2}$ in. in exterior dimensions, and in the second case of four vertical channels arranged with their flats forming four opposite sides of an octagon and wrapped at intervals with batten plates bent round in the form of an octagon $7\frac{1}{2}$ in. across the flats. Only the concrete lying within the exterior dimensions of the steelwork was included in the calculations. All the columns were 7 ft. long.

Four of each type were tested, two filled with concrete and two without concrete. The plain steel columns withstood an average total load of 67 tons on an area of 4 sq. in. in the case of the angle construction before failure; and 68 tons on an area of 4.76 sq. in. in the channel construction, which was not securely braced.

The addition of concrete increased the maximum loads before failure to an average of 98 tons on a total combined area of 42.25 sq. in. in the angle reinforcement, and to 96 tons and 112 tons respectively on an area of 49.75 sq. in. for the two channel-bar columns.

The modulus of elasticity of the steel being known, and the compression of each column under successive loadings being measured, the modulus of elasticity of the concrete and its corresponding stress can be calculated. In the case of the angle-bar columns, this modulus was 21,000 lb. per sq. in. at a stress of 60 lb. per sq. in., but decreased as the stress on the columns increased.

Finally, a description of the method of failure of the various columns was given; also curves showing the lateral deflection and main compression. The author concluded by suggesting that the tests would justify working stresses as high as 500 lb. to 750 lb. per sq. in. in columns of this nature, and possibly higher stresses for structures of unusual magnitude.

WORLD'S PRODUCTION OF IRON AND STEEL.

A return issued by the Board of Trade showing the output of iron ore, pig iron, steel, and manganese by the principal producing countries of the world states that the principal producers of iron ore and the outputs for 1908, 1909, and 1910, respectively, were: The United States, 35,925,000 tons, 51,155,000 tons, and 56,890,000 tons; Germany (including Luxembourg), 23,888,000, 25,095,000, and 28,248,000; United Kingdom, 15,031,000, 14,804,000, and 15,226,000; France, 9,895,000, 11,699,000, and 14,250,000; and Spain, 1908 and 1909 only, 9,123,000 and 8,645,000 tons. In regard to pig iron, the principal producing countries for the same years were: The United States, 15,936,000 tons, 25,795,000 tons, and 27,304,000 tons; Germany, 11,616,000, 12,442,000, and 14,556,000; the United Kingdom, 9,057,000, 9,532,000, and 10,012,000; and France, 3,346,000, 3,516,000, and 3,968,000. The total for 1910 is estimated at 65 million tons. The total output of steel for the same year is put at between 59 and 60 million tons, of which the United States, Germany, and the United Kingdom produced more than 46 millions. The actual figures for 1908, 1909, and 1910 are: The United States, 14,023,000, 23,955,000, and 26,095,000 tons; Germany, 11,006,000, 11,856,000 and 13,479,000; the United Kingdom 5,438,000, 6,018,000, and 6,515,000 tons. Manganese is produced mainly by British India and Russia. The figures for the former country are: 674,000, 643,000, and 801,000 tons, and for the latter, 1908 and 1909 only, they are 295,000 and 652,000 tons.

Change of Address.

In consequence of the increase in business, Messrs. D. G. Somerville and Co. have now removed to larger offices at 120, Victoria Street, Westminster, where all future communications should be addressed. The works address remains as heretofore—Archangel Wharf, New Cross, S.E.

Filling Holes in Concrete Walls.

Holes in concrete walls left by the tie rods of the forms have been filled by forcing corks into them and then ramming the holes with grout. A negro workman at one of the filter beds at New Orleans thoughtlessly jammed the cork of an empty bottle into one of the holes he was supposed to fill with grout. An engineer saw this and shortly afterward ordered enough corks to fill all the holes, which had previously given more or less trouble from leakage. Corks slightly larger than the holes were used and rammed to the centre of the wall with a rod having a collar several inches from the end and provided with a metal weight arranged so that it would slide along the rod and act as a hammer. The remainder of the hole was then readily grouted.

REINFORCED-CONCRETE WHARVES AND WAREHOUSES.*

By S. H. ELLIS, M.Inst.C.E.

This paper describes works recently constructed, under the author's supervision, beside the Whang-Poo River, near Shanghai, in North China. These comprise a reinforced-concrete piled wharf, 1,160 ft. long by 174 ft. wide, with a minimum depth of 21 ft. of water at its face; a reinforced-concrete quay-wall 495 ft. long and 21 ft. high; and two reinforced-concrete four-storey warehouses, each 300 ft. by 100 ft. in floor-area; as well as offices and staff-quarters, sheds for temporary storage of goods, and a power and light installation.

The question of foundations was dealt with at some length, the site consisting of river-deposited silt to an unexplored depth. The wharves and lighter buildings are founded on groups of reinforced-concrete piles. The warehouses rest on a raft of reinforced concrete (girders, beams, and foundation-slab), connecting the column-bases with a grill 4 ft. 6 in. to 5 ft. deep.

A brief account was given of the methods employed in driving the wharf-piles, of which over four thousand were used, and in the formation of the superstructure. The chief feature of the latter is that all members but the pile-caps, beams, and deck, were moulded on shore, and erected in place when matured.

The quay-wall is built along a tributary creek, and consists of a thin vertical wall and horizontal deck connected by buttresses, the whole founded upon piles. A slight forward movement of the structure was described, and the means adopted to ensure its stability.

The warehouses have reinforced-concrete floors supported on columns, the chief feature of which consists in the vertical bars being bound with a continuous rod wound spirally and enclosing an area of heavily stressed concrete. The interior first-floor columns are designed to carry a safe working-load of 376 tons each.

The nature and method of preparation of the concrete were briefly described, and the average records were given of three series of compression tests which were made (on the site) with 8 in. cubes of 1 : 2 : 4 mixture. These gave average results of 2,540 and 2,811 lb. per square inch at 3 months, and 4,137 lb. per square inch at one year.

The various methods of reinforcement employed were outlined, and the basis of calculation was stated. The points chiefly dwelt on were, first, the reinforcement of the lower columns in the warehouse; secondly, the general methods of ensuring that the steel skeletons were firmly bound together, with no loose pieces; and thirdly, the particular plan of effecting this in the wharf-girders, by employing a built-up reinforcement of angle and flat bars riveted together.

A description was given of tests to destruction which were carried out on a full-sized experimental wharf-beam, a warehouse-beam of corresponding character, and five experimental columns of reduced size; also of loading-tests applied to the warehouse first-floor columns.

* Abstract of a paper read before the Institution of Civil Engineers.

REINFORCED CONCRETE GRAIN ELEVATORS.

A Huge Plant.

The accompanying illustrations show a huge reinforced concrete grain elevator at Fort William on the Grand Trunk Pacific Railway, U.S.A., said to be the largest of its kind in the world. It is designed in four units of 10,000,000 bushels each, the first section with a capacity of 3,500,000 bushels, having been completed last year. The object embodied in the scheme is to take advantage of lower freight rates on the great lakes, and to rush wheat in the "fall months" from the threshing machines through the country receiving houses to the terminal elevators or silos on Lake Superior, where it is loaded into lake vessels. For the prompt and efficient handling of the western crop unusual facilities are necessary at the head of the lakes.

The plant, which was designed by the Canadian Stewart Co., Ltd., consists of a working house with a capacity of 750,000 bushels, a storage annexe of 2,750,000 bushels capacity, a four-track receiving shed, a dryer house, a boiler house, a switchboard room and transformer house. In front of the working house a concrete dock 337 ft. long has been constructed for the accommodation of vessels receiving their cargoes of grain. The working house consists of 75 circular concrete bins, having an inside diameter of 12 ft. and rising to a height of 79 ft. They are arranged in five rows of 15 bins each, forming 56 interstice bins, and making the working house 69 ft. wide by 237 ft. long. These bins are supported by a series of octagonal columns forming a working storey 20 ft. high. Surmounting the bins is a structural steel cupola 83 ft. high, sheathed with corrugated steel and roofed with concrete.

The annexe consists of 70 circular concrete silos arranged in ten rows of seven each. They have an inside diameter of 23 ft. 3 in., and are 95 ft. high. Fifty-four interstice bins formed between the circular silos are also utilised for storage. The silos are supported on a concrete mattress and walls. The cupola over the annexe is of steel construction, and is roofed with concrete. Five overhead bridges connect the storage annexe with the working house, and provide passageway for the conveyors, while steel galleries and cross walks are built over the silos in the annexe with open areas between; thus making it possible to heap the grain above the top of the bins.

FIRST SECTION OF 40,000,000-BUSHEL ELEVATOR, FORT WILLIAM

COMPLETED SILOS AND STEEL FRAMES OF TRACK SHED AND CUPOLAS.

Between the working house and the storage annexe is the track shed, a steel-framed structure 68 ft. wide by 240 ft. long, having a concrete foundation and roof. It contains four tracks with pit and shovel accommodation for twenty cars, which may be unloaded at one time.

The preliminary work entailed by an undertaking of such magnitude as the construction of the Grand Trunk Pacific

elevator may be realised when it is stated that fifteen men were employed at the Walkerville office of the contractors for many months, designing, drawing, and tracing, every little detail being drawn out before construction.

The actual work of construction began on November 21st, 1908, from which date excavation for foundations was vigorously pushed forward. Pile driving closely followed (the pilings consisting of 12,000 timbers 60 ft. long); and with the advent of spring, the site was ready for the concrete foundation proper.

The methods of handling and placing concrete in the foundation did not differ much from the general practice in such work, but it is noteworthy to remark the rapid progress made. While the first concrete was laid in March, the foundations were completed to the top of the bin supporting floor in May. During the time the foundation was being done, the circular silo forms were made, and when the bin supporting floor was laid, the silo forms were ready for placing. These forms, embodying the experience of years of concrete grain elevator construction, are an evolution from the crude methods formerly employed on circular bins. An absolutely smooth surface without break or unsightly rings and offsets is obtained by their use. The laying of concrete is practically continuous from the plac-

FOUNDATION AND SUBSTRUCTURE, GRAND TRUNK PACIFIC ELEVATOR, FORT WILLIAM, U.S.A.

CONVEYOR BELTS AND SPOUTS ABOVE BINS IN STORAGE ANNEXE.

of the bottom until the top of the silos reached. The forms in general consist of an inner and outer wall section 4 ft. high which are held apart by yokes, a sort of steel clothes pin made up of plates and channels and supported by lifting racks, an ingenious device patented by Messrs. W. R. Sinks and R. H. Folwell, of the Canadian Stewart Co., Ltd. The essential element of the invention is a hollow jack screw through which is inserted a vertical rod and upon which the jacks are made to climb and thereby raise the forms. In operating the jacks, a workman inserts a bar in a socket, causing a screw to turn. By turning to the right the forms are lifted, and by turning to the left the jack itself climbs the rod, while the forms remain stationary, being supported by the adjacent jacks. By reason of the rod passing through the jack the load is applied concentrically, and thus any tendency for the forms to bind is eliminated. Another great advantage of the device is that it does not have to be dismantled when a new length of rod is inserted. By this system the position of the horizontal reinforcing rods may be marked on the jacking rods, which is a matter of great convenience; also, daily progress of the work may be accurately observed, and the forms are kept level throughout the entire work by reference to the marks. The forms of the separate silos, though constructed in sections, are tied together by an arrangement of rods attached from yoke to yoke, making a united system

and providing an ample floor space for workmen. For each silo eight yokes and jacks were used, operated in sequence, one being turned a little at a time. The annexe walls were completed on August 15th. In the meantime the working-house bins were rising and the final concrete was placed on August 31st. Immediately upon the completion of the silos, the erection of the steel cupola framing was commenced. Fifteen hundred tons of steel was used in the construction. In December, 1909, the framing for the cupolas had been erected and enclosed and the floors and roofs were completed. All roofs are covered with five-ply composition pitch felt and gravel, while the window frames are of sheet metal glazed with $\frac{1}{4}$ in. wire-ribbed glass, and all doors steel-clad.

Portland cement arrived in Fort William in large cargoes, and it was necessary to provide ample warehouse facilities to hold it until wanted on the work. A cement shed capable of storing 12,000 barrels of cement was connected with the various cement mixing plants by means of railway tracks, sand and gravel for concrete were dredged from Lake Superior, and travelling hoppers received these materials from a whirley. The concrete mixing plant consisted of four No. 2½ Smith Mixers and Lidgerwood hoisting engines. Four hoist towers and hoppers were constructed and necessary track was laid early, so that when the work was ready for concreting to begin, the mixing plant was completely

installed. This plant handled during the course of construction 60,000 cubic yards of concrete, and its efficiency is evidenced by the fact that as much as 800 yards was mixed and placed in a single day.

For forms and moulds 2,000,000 ft. of pine lumber were used, while the steel bars for reinforcing amounted to 2,500 tons. Round bars were used in girders and floor slabs. Horizontal reinforcement in the concrete silos consisted of flat steel bands, spiral reinforcement being employed for the concrete columns supporting the working-house bins.

THE ARCHITECTURAL POSSIBILITIES OF STEEL.*

By HENRY C. CHARLEWOOD, F.R.I.B.A.

Earlier in 1911 a very interesting lecture was delivered by Sir William Richmond at the Armstrong College of Science entitled "Universities and Art Teaching," and I venture to call attention to some remarks of his on the subject of "the possibilities of steel as a material that will answer the æsthetic demands—i.e., what is beautiful plus what is useful, and per chance economical."

"In my opinion" (says Sir William), "and I give it for what it is worth, steel is a material which has in it somewhere and somehow great though different possibilities of beauty from those of wood and stone. Perhaps a new beauty, one to which she shall have to get accustomed, but which, and this I believe to be a certainty, will never be attained by imitation of construction or ornament which essentially belongs to other materials."

Sir William's theory is by no means a new one, but now that we find ourselves in an age of steel, it behoves architects to be always keeping their eyes open to

*Extracted from the Presidential Address delivered to the Northern Architectural Association, Newcastle-on-Tyne.

SECTION OF GRAND TRUNK PACIFIC SILOS, FORT WILLIAM.

its possibilities. At present we are very much afraid of letting it be seen, much more so than some of our Continental neighbours. We erect a steel building and then cover it with stone or some other material; but if a building could be designed in such a manner that we should be satisfied with the appearance of steel construction we should have a style which would be original and belong solely to the twentieth century.

The stone age has had its revival to a surprising extent, especially in some of the leading streets in London, and, though stone is by no means unsuitable for our large towns, it must be confessed that it does not meet with much originality of treatment. In the case of large buildings the classic orders are generally made use of in some form or other over and over again.

Though many leading men have taken up the question as to how steel buildings are to be made beautiful, I know of no really satisfactory solution of this difficult problem. A few years ago, an admirable design for a Gothic cathedral, with steel construction to be covered with lead, by one of our leading architects, was exhibited on the walls of the Royal Academy, and reproductions of it are familiar to most of us; but on looking at it one feels that though the construction is intended to be of steel, it could be carried out more suitably in stone. The wide buttresses with their weatherings and canopies are all suggestive of stone construction. What is wanted is an entirely new type of architecture suitable for visible steel construction, without any attempt at concealment. A great deal could be made of the treatment of very plain steelwork in coloured decoration, provided that there was no attempt to give to the metal the appearance of another material.

I do not venture on any suggestions as to the way in which steel buildings could be designed, but feel sure that, had the problem presented itself to some great nation like the ancient Greeks, they would have been equal to the occasion, and have overcome the apparently overwhelming difficulties in some very natural and simple manner. Perhaps the problem will be solved in some country where there are no examples of ancient architecture, and where architects will have their minds unbiassed by any early traditions.

There is one feature which is absent from all our modern towns, and which, no doubt, as matters now stand, would not come within the Corporation By-laws, but which I think is a decidedly attractive feature. I refer to the covered way. In my young days I was often in the town of Nottingham, and I have a very vivid recollection of the advantages of the covered way in what I believe is still known as the "Long Row." There you were independent of rain or snow, and seeing that rain is an element to be reckoned with in this country, that is a great consideration.

Covered ways could not now be carried out in England on the lines of those in Italian towns, where the exclusion of the sun is the chief requirement, and it is customary to bring the upper part of the buildings in the streets over the flagged footpaths, supported on rows of stone pillars either with or without arches, which give some very effective shadows underneath. These are very picturesque, but would not lend themselves to the requirements of modern tradesmen; but I think that covered ways could be designed of steel in a way which would not necessarily be a detriment to the general effect, and the light could be obtained by means

of prismatic glass where light was most required. I imagine the roofs to be flat and covered with lead for the most part, or possibly with some cheaper form of covering, but never lean-to roofs glazed after the manner of a greenhouse; vide catalogues of metal castings.

It would not be easy to apply them to our street buildings as they now stand without considerable detriment to their appearance; but, if buildings with visible steel construction became the order of the day, I think that covered ways would follow as being specially adapted to buildings of that nature; and I am quite sure that those towns which had covered ways would be very popular for shopping centres, owing to the gain in comfort insured thereby; and on the occasion of any great public function the flat roofs would be very useful as raised platforms from which a good view of processions in the streets could be obtained. Something in the nature of a covered way has lately been effected in Newcastle in front of the premises of a well-known firm of tradesmen in Market Street; and though it may be said to be of a purely utilitarian character, it has one great advantage, viz., that people can look at the goods displayed in the shop windows for as long as they like, without being in the way of pedestrians.

What I have said as to buildings of steel construction also applies to some extent to reinforced-concrete buildings. I should like to see the external surface of reinforced-concrete buildings treated decoratively with either mosaic work or tiles, which would give the impression of having been applied, whereas stone or brick give the wrong impression that they are constructional features. The building up of a projecting cornice in reinforced-concrete to look like a classic stone cornice cannot be said to have a particle of truth in its favour, and if we give up all attempts to be true in our construction very little can be hoped for the architecture of the twentieth century.

The imitations of the materials themselves are very much to be deplored. Stone and marble are imitated so closely that even a stonemason may be deceived at first sight; and cheap kinds of wood are scratched and stained to give the impression of oak.

Architecture which depends upon shams both in its materials and construction for its general effect will never seriously impress the minds of any thinking people.

YIELD POINT AND ELASTIC LIMIT.

BRITISH STANDARD DEFINITION.

The Engineering Standards Committee, supported by the Institutions of Civil Engineers, of Mechanical Engineers, and of Naval Architects, the Iron and Steel Institute, and the Institution of Electrical Engineers, have just issued the British Standard Definitions for Yield Point and Elastic Limit (Report No. 56), copies of which can be obtained from the offices of the Committee, 28, Victoria Street, Westminster. The full text is as follows:—

The main committee having been approached with the request that standard definitions for the terms "yield point" and "elastic limit" should be drawn up, remitted the matter to those sectional committees which had prepared standard specifications for steel and wrought iron, with the result that the following definitions have been unanimously agreed upon. At the request of the Ships Committee, a note is added with regard to the use of

these terms in the commercial testing of materials used in the construction of ships and their machinery.

Definitions.

Elastic Limit.—The Elastic Limit is the point at which the extensions cease to be proportional to the loads. In a stress-strain diagram plotted to a large scale it is the point where the diagram ceases to be a straight line and becomes curved.

Note.—The Elastic Limit can only be determined by the skilful use of very delicate instruments and by the measurement of the extensions for small successive increments of load. It is impossible to determine it in ordinary commercial testing.

Yield Point.—The Yield Point is the point where the extension of the bar increases without increase of load.

Practical Definition of Yield Point.—The Yield Point is the load per square inch at which a distinctly visible increase occurs in the distance between gauge points on the test piece, observed by using dividers or at which when the load is increased at moderately fast rate there is a distinct drop of the testing machine lever, as in hydraulic machines, of the gauge finger.

Note.—A Steel test piece at the Yield Point takes rapidly a large increase of extension amounting to more than 1/200th of the gauge length. The point is strongly marked in a stress-strain diagram.

Note added by request of the Ships Committee.—The Sectional Committee on Sections and Tests for Materials used in the construction of Ships and the machinery, while concurring in the foregoing definitions, desires however to make the following remarks with regard to the use of the terms "Yield Point" and "Elastic Limit" in connection with Steel and Wrought Iron for Shipbuilding.

The Ships Committee does not recommend the use of either "Yield Point" or "Elastic Limit" in the Standard Specifications for Ship Material for the following reasons:—

Yield Point.—In regard to the attainment of the Yield Point there is considerable divergence of opinion as to the best method of determining it, and methods involve greater time and cost than can be expected in the works. While it is possible in works by careful test at a greatly reduced speed to obtain the Yield Point in ordinary mild steel and wrought iron, some of the harder steels and other constructional materials have no defined Yield Point at all, and so have no Elastic Limit.

Elastic Limit.—It is quite impossible to determine the Elastic Limit in time available for ordinary commercial testing. In its determination a special delicate and accurate extensometer must be used, in the hands of a careful competent observer, and the determination for each test bar would require considerable time. It is properly a matter to be left to laboratories organized for scientific purposes.

The Ships Committee is of opinion that the present method of fixing, by experience, the working stress for material as a proportion of the ultimate breaking stress rather than as a proportion of the Elastic Limit or Yield Point, is the best practical method. It therefore considers that the inclusion in the British Standard Specifications for Ships Material of tests to ascertain the Elastic Limit or the Yield Point would not justify the dislocation of the ordinary commercial testing as carried out in Works Test Rooms which would be entailed thereby.

TRADE AND CRAFT.

Structural Ironwork.

At the extensive new premises of Messrs. Whiteley's, Ltd., in Bayswater, we are informed, fire-escape stairs, and the balconies which are used for connecting these stairs, and also for loading purposes, were supplied by the St. Pancras Ironwork Co., Ltd. In this connection a rather interesting problem arose regarding the obstruction of light, and in order to solve it the company's patent renewable ferro-concrete treads, which had been originally specified for all the stairs, were eventually replaced by perforated iron treads and risers, made to meet the ordinary requirements of the London County Council, the concrete treads being used in one staircase only, and in small portions of the other stairs where the conditions rendered a non-slippery tread specially advisable. We understand that the stairs were made and fixed in a remarkably short time.

The problem of avoiding loss of light where stairs have to be supplied to meet the necessities of escape in case of fire is illustrated in an interesting way at another large public building where the stairs were being made by the St. Pancras Company at the same time as those for Messrs. Whiteley, namely, the new Polytechnic building in Regent Street. Here it was arranged to construct most of the landings as pavement lights, so as to give the greatest amount of light to the windows below. Such an arrangement is, of course, an expense which owners who are obliged to put in fire-escape staircases might be anxious to avoid, but the resulting economy of light is such as to justify the adoption of glazed landings in many cases. Another instance where this has been done is in the case of escape landings outside the windows at the new Barnato Memorial wing of the Middlesex Hospital.

The old St. Pancras Company referred to is now in process of reorganisation. We understand, however, that the work being done continues on a very large and satisfactory scale, and that the new management entertain lively hopes of greatly extending the operations of this well-known old company, who are now better equipped than ever to deal promptly with any work entrusted to them. The work done in pavement lighting in Manchester and elsewhere during the last quarter of 1911 has been very large, and the fire-resisting door department has been very busy. The foreign and colonial contracts now on hand amount to large sums, including galleries, chambers, and flooring for high-tension electric switchgear in India; in addition to which large orders for stable fittings have just been completed for Louis Castells, Esq., Buenos Aires, and for H.H. the Maharajah Gaekwar of Baroda; also a repeat order for specially designed stall divisions and mangers for the quarantine and sanitary authorities at Alexandria, Egypt.

Lift Installations.

In connection with extensions and additions now being carried out to Messrs. Bek, Frean and Co.'s premises at Bedfordsey, Messrs. Smith, Major and Stevens, Ltd., of London and Northampton, have received instructions for the installation of one of their full automatic push-button electric passenger lifts, and a large electrically operated goods lift. Among other important contracts

at present in the hands of Messrs. Smith, Major and Stevens, Ltd., are the following:—For the Admiralty: 6 full auto-button-controlled passenger-lifts for each of H.M. battleships "Ajax," "Thunderer," "Monarch," and "Conqueror" (similar machines have recently been completed by them on H.M. battleships "Neptune" and "Orion"); 2 electric passenger lifts for Messrs. Boots' premises at Bath and Derby; 2 electric passenger-lifts for the Swansea General Hospital; 2 electric lifts for Messrs. Anderson, Son and Hedley's new premises, Newcastle-on-Tyne; 12 machines for export to Australia; 2 for Wellington, New Zealand; and 6 for South America.

INSTITUTE OF BUILDERS' DINNER.

The annual dinner of the above Institute was held in the Whitehall Rooms, Hotel Metropole, on Wednesday, January 24th, Mr. James S. Holliday, President, being in the chair. Among those present were Messrs. W. Nicholson, J.P., Gerald C. Horsley, Edgar Horne, M.P., C. W. Ball, J. Arcsott-Bartrum, E. J. Brown, Jas. Carmichael, C. FitzRoy Doll, F. L. Dove, B. I. Greenwood, L. Horner, F. G. Minter, C. F. A. Voysey, H. D. Searles-Wood, Wm. Willett, Maurice E. Webb, T. G. Costigan, secretary, and many others.

Mr. H. H. Bartlett, proposing the toast of the "Architects and Surveyors," said they had heard a good deal recently of the responsibilities of the architect. The architect, however, saddled himself with many trivial responsibilities which any number of builders would be glad to bear. Why should the architect trouble himself, for instance, about the price of a pair of butts? Many specialists were now engaged in building work, and all that the builder had to do was to pay the accounts and take the general responsibility.

The architecture of modern times had vastly improved; and it compared very favourably with that of past years. New materials were constantly being introduced. Reinforced concrete was comparatively new, but he was confident that from it the architect would be able to produce a building that they could look at with pride.

The surveyor was a friendly medium between the architect and themselves; he carried out his work well, and it was the builder's own fault if he did not know how to price his quantities.

Mr. Gerald Horsley, responding for the architects, referred to the cordial relationship which now existed between architects and builders. This mutual understanding was founded upon one common desire—that good work should be done. In that way only could the obligation to the client be fulfilled. Having commented upon the work of the association, Mr. Horsley said that, supplementary to the teaching and apprenticeship through which all young architects had to go, two objects were held in view: (1) That the student should become an accomplished designer and a first-rate artist, and (2) that he should have a thorough acquaintance with the arts and crafts connected with architecture and building. In the accomplishment of this latter end, the builders could materially assist, for in the builders' yards they were accustomed to find the best technical work. The British workman, he believed, was the best; he should be

encouraged to produce the best work of which he was capable, and he should be assured that his so doing would gain for him much more than a living wage.

Mr. Edgar Horne, M.P., responded humorously for the surveyors. The surveyor, he said, was more permanent than the architect; architects were only a fashion. If a work were pulled down in forty years' time, another architect would put up a different building altogether. But if a surveyor said that a certain area of land was an acre, it would still be an acre of land a thousand years hence, and not an inch less. The architect was the bully who was always asking for what it was impossible to give.

Mr. H. D. Searles-Wood, proposing the toast of "The President," said that an inspection of the Victoria and Albert Museum would convince everyone that Messrs. Holliday and Greenwood built "diligently and faithfully." The speaker then quoted from some ancient Babylonian building by-laws, which were framed on the principle of an eye for an eye, a tooth for a tooth. One of these decreed that if a house fell and killed the owner the builder also should be put to death. Mr. Holliday, concluded Mr. Searles-Wood, was a gentleman of wide experience, and one who was interested in many religious and philanthropic institutions.

Mr. J. S. Holliday, replying, said it had been his privilege for thirty years to be associated with Mr. Greenwood, and he was glad to say how successful that union had been. Turning to the affairs of the Institute, the speaker said they had not had a brilliant season, but good work had been done in two matters of trade importance. A form of contract with specialists had been drawn up by his Council, approved by the L.M.B.A., and practically accepted by the National Federation. He hoped that this would prove a fair and honourable contract all round. A committee had been appointed to consider the resuscitation of the apprenticeship system, and the proposed draft of indentures had been practically accepted by the L.C.C. Mr. Holliday then described the good work that was being done for education at the Brixton School of Building. The Institute, he said, had canvassed the whole trade throughout the kingdom, and the replies had been practically unanimous in favour of apprenticeship. Trade was undoubtedly improving, but clouds of depression were still hovering around. Some attributed this to the persistent demand for shorter hours and larger wages, others to legislation. Legislation had certainly affected the building trade during the last few years, but he hoped that, if let alone for a time, they would return to one of those periods of prosperity which now were nearly long ago.

Mr. B. I. Greenwood then proposed the final toast, "The Guests," to which Mr. FitzRoy Doll replied.

MANUFACTURING STONE FROM SLAG.

The American Consul at Nuremberg, in discussing the manufacture of building stone from smelter and blast-furnace slags, states that it is an industry of considerable importance in Germany, and is carried on to a greater or less extent by the owners of nearly all such plants. The process is not patented, and is very simple in details, and practically all blast-furnace and smelter slags are suitable for

the purpose. The slag, however, must be in granulated state. After it has been allowed to harden it is unsuitable, and all attempts to utilise slag which has been crushed or ground, having once hardened, have failed to produce a solid stone.

The slag is granulated by the addition of water as it flows from the oven or furnace. It is then mixed with lime—pulverised slaked lime or milk of lime—in the proportions of 7 to 10 parts of slag to 1 of lime, according to the nature of the slag, and while in this condition it is subjected to pressure in moulds of the desired size and shape by means of a special type of press capable of exerting a pressure of 22,000 to 50,000 kg. Having been thoroughly mixed with the required proportion of lime, the granulated slag is allowed to stand for one hour before being put through the press, and when pressed the stones are stacked in the open air.

After three or four weeks, according to the weather, they are ready for use. They harden slowly in a low temperature, and if subjected to frost before they are thoroughly hardened they are liable to crumble. In the winter the stones may be hardened in steam-heated rooms. The stones grow harder with time, and after several years are stated to have a resistance of 100 kg. per sq. cm.

BUILDERS' FOREMEN'S ASSOCIATION DINNER.

The eighteenth annual dinner of the above association was held in King's Hall, Holborn Restaurant, on Saturday evening last, Mr. Joseph Randall presiding. A large company was present, amongst whom were noticed Messrs. B. E. Nightingale, W. A. Harford (of Higgs and Hill), Brees Homan, J. W. Jerram, Frederick Purton, G. W. Holt, William Regan, George Thompson, Thomas Costigan, T. Evans, W. Townsend, and Benton Rees.

Mr. Joseph Randall, proposing the toast of "The Builders' Foremen's Association," explained that he was present against the strict injunctions of his medical adviser, and he hoped they would excuse his early departure. He recalled the fact that he had occupied the presidential chair of the Builders' Benevolent Institution in 1884. With regard to their own association, he was pleased to say that, by the energetic management of the committee, they would be able to increase the amount of pensions by 2s. per week from June next.

Mr. G. W. Holt (president), in reply, said their thanks were due to their many friends for subscribing so generously towards the pension fund, and to Mr. Joseph Randall for his presence among them that evening. The pension fund, he continued, was founded only nine years ago, and it was something to be proud of that the balance in hand now stood at £1,380 3s. 7d. This, in itself, without any other inducement, should be sufficient to bring in many new members. He cordially invited all non-members to come in and assist in the noble work of preparing for the evening of their lives.

Mr. Thomas Costigan, proposing the toast of "The Building Trades," attributed the depression in business to Government legislation. He would like to say how much the master builder owed to his foreman. A good foreman would turn everything in the right way, but a bad one would produce a deficit.

Mr. B. E. Nightingale, in reply, spoke hopefully of a revival in trade. He was convinced that it must come eventually.

Mr. T. Evans (vice-president) then proposed the toast of "The Visitors," to which Mr. W. Townsend replied.

COMPETITIONS.

The Scottish National Memorial to King Edward VII.

The following six selected architects have, it is understood, accepted the invitation of the Executive Committee to send in designs for the Scottish National Memorial to the late King Edward VII.:—Edinburgh—Mr. Hippolyte J. Blanc, R.S.A.; Mr. G. Washington Browne, R.S.A., and Sir John Robert Lorimer, A.R.S.A. Glasgow—Mr. J. J. Burnet, A.R.S.A., and Mr. H. E. Clifford, F.R.I.B.A. Inverness—Mr. R. J. Macbeth, F.R.I.B.A. The memorial is to be associated with Holyrood Palace and its surroundings.

LIST OF COMPETITIONS OPEN.

FEBRUARY 3RD. NURSES' HOME, BOLTON INFIRMARY.—Premiums, £30, £20, and £10. Mr. John B. Gass, F.R.I.B.A., has been appointed the assessor.

FEBRUARY 17TH. NEW OFFICES FOR THE PORT OF LONDON.—The Port of London Authority invite preliminary sketch designs for new head offices in Trinity Square, and for lay-out of a building site. Sir Aston Webb, R.A., is the assessor.

FEBRUARY 17TH. ELEMENTARY SCHOOL, YORK.—The City of York Education Committee invite competitive designs for a public elementary school to be built in Campleston Lane, Bishopthorpe Road. Assessors, Messrs. T. Mellard Reade and Son, Liverpool. Apply, J. H. Mason, secretary, Education Offices, Clifford Street, York.

MARCH 15TH. LAYING OUT ESTATE, PRESTATYN.—Designs for laying-out the Prestatyn Estate are invited. Premiums of £50, £30, and £20. Application (with 19s. 6d. deposit, returnable) was to be sent by January 8th to Lord Aberconway and the Trustees of the Prestatyn Estate, 33, Henrietta Street, Strand, W.C. Designs by March 15th. Judge, Mr. H. V. Lanchester, F.R.I.B.A.

MARCH 16TH. PUBLIC OFFICES, HARROW.—Harrow-on-the-Hill Urban District Council invite designs for enlargement and alterations of their public offices, at a cost not to exceed £4,500. Premiums, thirty, twenty, and fifteen guineas. Plan and instructions (£1, returnable) from Mr. J. Percy Bennetts, Engineer and Surveyor to the Council, Council Offices, Harrow-on-the-Hill. R.I.B.A. will be asked to appoint an assessor.

MARCH 31ST. NEW PARLIAMENT BUILDINGS, WINNIPEG.—Regulations governing the competition for the new Parliament buildings for the City of Winnipeg may be had from the High Commissioner for Canada, 17, Victoria Street, Westminster. [The date formerly announced for the close of this competition has been extended from that formerly announced.]

AUGUST 30TH. THE HENRY SAXON SNELL ESSAY.—The Henry Saxon Snell prize of fifty guineas and silver medal of the Royal Sanitary Institute is offered for an essay on "Suggestions for Improvements

in the Ventilating, Lighting, Heating, and Water Supply Appliances and Fittings for an Operating Room and its accessory rooms for a General Hospital of 400 Beds (no Students)." Essays (in which two competitors of different professions or crafts may join) to be delivered before 4 p.m. August 30th, to the Secretary, Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., from whom full particulars may be obtained.

LONDON MASTER BUILDERS' ASSOCIATION.

A council meeting of the London Master Builders' Association was held at the offices, Koh-i-Noor House, Kingsway, W.C., at 4 p.m., on Thursday, January 18th, when the chair was taken by the President, Mr. G. Bird Godson.

The Finance Committee's report was submitted, and the Council, on the committee's recommendation, agreed to discharge in full up to date the claims made upon the association on behalf of the National Federation Reserve Fund.

The Amalgamated Society of Carpenters and Joiners gave official notice to terminate the existing working rule agreement on June 8th next, and with the notice was forwarded a proposed new working rule agreement which was signed jointly by the secretaries of the Amalgamated Society of Carpenters and Joiners and of the Furnishing and Cabinet-Making Societies. It was proposed to hold a conference with the object of discussing the recognition of the latter society, which the Council had declined to acknowledge as a branch of the building trade. The Council maintained its objection and declined to hold a conference to consider the matter.

The following were elected ordinary members of the association:—Mr. B. E. Nightingale, Albert Embankment, S.E. Messrs. E. A. Roome and Co., 36, Basinghall Street, E.C.; Messrs. W. Blay Ltd., Dartford, Kent; Messrs. F. and F. J. Wood, 64, Cleveland Street, Mile End, E.; Messrs. Lole and Co., 12A Trafalgar Square, Chelsea, S.W. The firm of Messrs. Arthur Newman, Ltd., Cranbrook Road, Ilford, E., was nominated as an ordinary member.

It was decided to hold the annual general meeting on Thursday, February 20th next, and the annual dinner in the Whitehall Rooms, Hotel Metropole, Charing Cross, on Thursday, February 22nd, and it is hoped that the President will be well supported by the members on both occasions.

Various matters of trade importance and interest were considered.—THOMAS COSTIGAN, Secretary.

OUR PLATE.

Mr. Louis de Soissons' design for the central space of a covered market, which has gained for him the Tite prize this year, is a brilliantly executed piece of work exhibiting the influence of French training, the drawings themselves being especially commendable.

Drawings of London and Oxford.

At the gallery of the Fine Art Society, 148, New Bond Street, W., there will be on Friday and Saturday next, from 10 to 6, a private view of an exhibition of water-colours of London and Oxford by Mr. Walcott, whose work as a delineator of architecture is of the very highest quality.

THE ARCHITECTS' & BUILDERS' JOURNAL.

WEDNESDAY,
FEBRUARY 7th, 1912.

Volume XXXV,

No. 890.

ST. ANDREW'S SQUARE, EDINBURGH. DRAWN BY HANSLIP FLETCHER.

This is one of a series of illustrations in "Edinburgh Revisited," by Mr. James Bone, recently published by Messrs. Sidgwick and Jackson, price 21s. net—a book notable alike for its literary and its artistic qualities.

FIG. '1. THE NAVE OF NOTRE DAME DU PORT, CLERMONT-FERRAND (PUY-DE-DÔME)

(From "*Romanesque Architecture in France.*")

THE ARCHITECTS' & BUILDERS' JOURNAL.

FEBRUARY 7th, 1912.

CAXTON HOUSE, WESTMINSTER.

VOLUME 35. No. 690.

NOTE : The List of Contents will be found on page IV. of the front advertisements.

French Romanesque Architecture.

WHERE does Romanesque architecture show so much architectural interest, such extraordinary variety of experiment and suggestion, as in France, and in the south of France more especially. German Romanesque, it is true, shows more of a coherent purpose; it is, in fact, a round-arched style, tolerably complete in its aims, and might very well have been developed into a still finer national architecture, had not the Germans been tempted aside from it to take up Gothic, which they only practised with very partial success, their Gothic being in artistic spirit far inferior to that of France or England. French Romanesque never required the consistency of a style; it was a series of experiments, of most extraordinary variety, into which were blended reminiscences both of Byzantine and of Roman architecture—the richness of the former and the monumental solidity of the latter. In the tenth century there were probably enough remains of actual Roman work in France to exercise a strong influence on the Romanesque builders, and over and over again we see the attempt to compel the forms of Classic architecture into the service of buildings of different proportions and for different uses than those of the Romans. Everywhere we find the engaged column, with a more or less rude imitation of the Ionic capital, trying to play the part of a buttress, the architectural expression of the function of the buttress having been yet arrived at; in some examples we almost find it, as one may say, in the very act of transmutation into buttress form. But the most noteworthy feature of the French Romanesque is its completely masonic character. Everything in it is monumental in expression and in material; instead of the wooden roofs of the Italian basilica we have the heavy barrel-vault built in stone, in some cases roofed outwardly also with stone slabs. And in this monumental character there is a variety in design, in the disposal of the structural portions and in the decorative carving, which renders it a remarkably suggestive style. It is full of architectural ideas which may be carried out in a rather crude manner, but which seem almost waiting for a more cultured and civilised age to take them up again and show what could be made of them.

It is partly for this reason that the collection of more than two hundred excellent photographs of French Romanesque architecture, issued with an introductory chapter by Mr. Julius Baum, ought to be a very welcome publication to architects, not merely for the historical interest of the examples given, but for their architectural value as a source of inspiration. The series of photographs includes a good number of churches which are not very generally known, and of interest of which has not been exhausted by repeated reproduction; and the photographic illustrations are so clear and fine in themselves that for the purpose of study they may to a great extent be said to supply the place of an actual inspection of the buildings. Of course, it would be incomplete if we had the photographs interleaved with

plans; but in the introduction a good many plans and sections are given; and the introductory chapter is a very well-written and able analysis of the phase of architecture which is illustrated in the photographs.

Dr. Baum considers that the experiments in church planning made in the Romanesque period were to a great extent due to a kind of contest between the traditional basilica church plan, as the most convenient for a congregation, and the central type of plan, as the most effective in an architectural sense. And but for the invention of cross-vaulting, the central type of plan might have conquered; it gave facility for the dome, the noblest and most effective form of monumental roofing. The barrel-vault roof of the long form of church, though most impressive in its monumental solidity, had the structural disadvantage of requiring very thick walls throughout the whole length of the building, instead of the concentration of weight at certain points rendered possible by the cross-vault; and it had the defect in regard to internal appearance, that the vault was always rather dark; to get windows into the springing of the vault involved rather difficult masonry construction, and so it was only lighted from windows below the springing. The interior of the church of Notre Dame du Port, Clermont-Ferrand (Fig. 1), shows the effect of this severe monumental manner of building; in this case there is an attempt to get more light into the vault by a window high up in the west wall, but this has only a very partial effect. Fig. 2 gives the transverse section of the church. Architectural severity could hardly be carried farther than in this interior, the arches

FIG. 2.—CROSS SECTION OF NOTRE DAME DU PORT, CLERMONT-FERRAND.

not having any kind of moulding. The two shafts, one in the foreground and one further down the building, which go up to the base-line of the triforium, look as if there had been the intention to carry out the system of building which is found in many of these barrel-vaulted churches, and also in many of the early cross-vaulted churches, of building a massive arch from side to side at regular intervals, below the surface of the vault and as if carrying it. Examples of this are seen in the interiors of the churches of Bussière-Badil and Preuilley (Plates 56 and 57 in the book), which are barrel-vaulted; and in the interior of Figeac (Plate 58) we see the same principle of the heavy transverse arches with the bays between them cross-vaulted. In the

FIG. 3.—NAVE OF THE CHURCH AT GENSAC (CHARENTE).

case of the cross-vaulting the heavy transverse arches between the bays may be thought to have steadied the abutment of the vaulting; in the case of the barrel-vault it is difficult to understand what advantage was supposed to be derived from them, as they could not avail to reduce the thickness of the walls and vault between these points; but it is possible that the transverse arches, built first, supported a centering for the vaulting between them—that is the only practical use one can suppose for them. The same employment of heavy-built transverse arches at intervals occurs in a good many of the Italian timber-roofed basilica churches, as in so advanced a building as San Miniato, for instance. In the case of the timber-roofed churches these arches served as structural ties to the walls, and added a greater effect of architectural solidity to the building.

This system of accentuating a timber-roofed church by solid-built arches across it at intervals has still an architectural value, and might be considered as an element of church design, provided of course that the plan, in the disposition and grouping of the points of support, gives an obvious motive for it. The erection of built masonry or brick principals to carry the purlins has been adopted in some modern churches; but that is not quite the same thing.

It is not likely that the built barrel-vault will ever be adopted again for churches, monumental and impressive as it is in a sense. In Romanesque France the desire in some quarters to substitute the central or the cross-armed type of plan for the long one led to the employment of dome-roofing, so specially suitable to this type of plan; and then the dome roofing was transferred to the long plan, as we see it at Souillac and at Gensac, and other churches in the Charente district, where the domes, instead of marking central points in the plan, are merely disposed in a row, one over each bay of the longitudinal plan. The interior

of Gensac (Fig. 3) shows the effect of this. It is a contradiction to the general ideal of a long form of plan, but has a very monumental appearance. Acoustically must be bad, but acoustics are not the only, nor should they be even the chief consideration, in church architecture. It is noticeable that in these domed churches of the Charente district the concave curve of the pendentive is not stopped on the extrados of the arches, but extends to their intrados, so that the faces of the voussoirs themselves continue the curve, instead of being in a vertical plane: the effect of this can be quite clearly seen in the photograph. The point is worth attention, as it may be a question for modern dome-builders whether this is not the most architectural manner of treating pendentives. It seems to convey the impression of being a more genuine piece of masonry structure than the usual treatment in the pendentives of Renaissance domes.

The engaged column used as a buttress is continuous with in French Romanesque, in the south especially. Sometimes, as in the transept of St. Pierre at Aulnay, we find half-columns planted against the wall as a kind of framework to the façade, without any pretence of carrying anything, the capitals merely stopping short with nothing on them; they wanted some way of framing in the wall and did not know what else to put except a column. Sometimes, as in the apse of the church at Savennières (Fig. 4), we see the column almost in the act of turning into a buttress; the capital ending in a kind of pyramid, from which a short square buttress rises to the under-side of the cornice. At Solignac columns and flat buttresses with set-offs at top are used alternately outside the apse, as if they had made up their minds which was the best form. A whole series of photographs affords a most curious picture of an architecture gradually growing into form by the putting together or modifying of details from older styles. Jazeneuil (Vienne) we find the apse decorated with a series of narrow pilasters with a concave moulding at the top.

FIG. 4.—APSE TO THE CHURCH AT SAVENNIÈRES (MAINE-ET-LOIRE).

The Institute and the Society of Architects.

THE negotiations which have been long going on between the Institute and the Society of Architects, with the object of the union of the two bodies to promote the passing of a Registration Bill, have, of course, been in the nature of private documents. The result of the meeting called to endorse them, however, has been printed in the Institute "Journal," and is practically therefore public property, and the refusal to endorse the proposals, by a large majority, shows, at all events, that there are a good many members of the Institute who are hostile to the scheme, at all events in its present form. It is perhaps no serious violation of the privacy of the meeting to say that the proposal lost nothing by the way in which it was brought forward, for a more able and masterly speech than that of Mr. Gibson, in moving the resolution, has seldom been heard at an Institute meeting. We should take it that the outline of the proposed Bill which the Institute were to undertake to promote, if the Society of Architects would amalgamate with them, had something to do with the general opposition; we cannot cite from a private document, but we may say that it embodied some proposals which Parliament would certainly never accept. What is to be the next step in the matter is not apparent; but our impression is that the amalgamation of the Society with the Institute is not very likely to take place now.

The Strand Building Site.

THE announcement that the London County Council have consented to sell the freehold of the site in the Strand island required by the Commonwealth of Australia marks an important new departure in their method of dealing with this land. An amendment that was proposed to the effect that the Council, while adhering to the principle of the retention of the freehold, welcomed the proposal for the sale of the land to a British Dominion, was defeated by 61 votes to 51. The object of the amendment evidently was to represent that this parting with the freehold was to be regarded as a special act of grace to the Australian Commonwealth, and not as a precedent. The refusal of the Council to accept this amendment implies that, with the view of turning this building property the sooner to account, they are prepared to depart from their policy of selling it only as leasehold, or at all events to leave it open to them to do so. Probably this decision will lead to a greater facility in disposing of the rest of the site, which has long lain unprofitably on their hands. Lord Alexander Thynne, the chairman of the Improvements Committee, referred to the scheme put forward three or four years ago by those who took the title of "The Strand Further Improvement Committee," with which, he said, he had never had any sympathy. He might well say so, for their proposal was one which was made too late, and was supported by absurd arguments. It was maintained that the Strand was constricted at its eastern point, which is actually the widest part of the street, the notion apparently arising merely from the fact that the road takes a curve to get round St. Mary's Church, and then returns to what would have been its straight line had there been no church to get round. The chief futility of their proposals, however, lay in the fact that the western part of the frontage had already been set out and built upon, according to the original plan proposed by the Council, and it was necessary to treat the remainder of the site in symmetrical conformity with the part already laid out. It would have been quite possible, by the sacrifice of some building land, to have made a fine *place* there, with St. Mary's in the centre of it, by setting back the north boundary line of the Strand, parallel with the south side of the street, far enough to align the north side with the line of street facing the Law Courts. That would have been so great a public improvement, would have given London such a fine open space, with the church and perhaps a strip of garden in the centre of it, that it would have been worth the sacrifice of some building land, in the public interest. But to have attempted

FIG. 5.—INTERIOR VIEW OF THE CHURCH OF SAINT
BENOÎT-SUR-LOIRE (LOIRET).

filled with a repeating flower which has somewhat the effect of the English ball-flower ornament; at St. Benoît-sur-Loire we find solid cylindrical stone columns, obviously reminiscent of the Roman column, but thicker in proportion, and with heavy richly carved quasi-Classic capitals. The view from the ambulatory aisle, looking into the church (Fig. 5), gives a good illustration of these Romanesque columns derived from Classic forms, and also shows the fine composition of the main building, with its effective contrast of blank wall and arcades. The value of blank wall in a design is, in fact, one of the lessons to be got from French Romanesque. Many suggestions, too, are to be got from the rich and effective carved ornament of these churches, which contains ideas that might be worked out further in a more refined and modernised form.

The plans which are given in the text of Dr. Baum's introduction form a good classification of different possible types of church plan; the three-aisled basilica with an apse at the end of each aisle; the single-aisled vaulted church with a transept and three apses on its eastern side (the centre apse of course larger and more important than the side ones); the three-aisled or five-aisled plan in which the line of the aisle is continued round a main apse, and an ambulatory. All these are types which might be used in modern church planning. A very remarkable French plan of this period, which is not given, is that of Parroux, which shows a great circular chapel at the east end, with an inner arcade. There must have been some special motive for such a feature; probably it was intended as a memorial or monument chapel. Though it is now what may be called a ruin, the glass gone out of the windows, and the floor covered with vegetation, the architectural features are in pretty good preservation, and the view of the interior (Plate 7 in the book) forms one of the most interesting in a remarkable collection of illustrations.

A SHEFFIELD IMPROVEMENT SCHEME.

changing the line after the lay-out of the site had been accepted and part of the buildings erected, would have been throwing away money for what would have been no architectural advantage.

Street Improvement at Sheffield.

A GREAT improvement in the entrance to Sheffield from the railway station, to which the municipal authorities will do well to give serious consideration, has been proposed by Mr. Gibbs, a well-known architect in that city. He proposes to carry a level street from the station, on a viaduct with an architectural portal in the form of a monumental arch; the space under the viaduct to be utilised as the wholesale market on the general street level. A considerable area of skylight is provided on the viaduct level to light the lower market. The spaces between the skylight (50 feet wide) might be rather deficient in light in dull weather, but with prismatic glazing there would be light enough for practical purposes. On the viaduct level it is proposed to build retail markets which would form architectural flanking façades to the viaduct road, with the principal block accentuated by a portico and a dome symmetrically placed on each side of the roadway. From the published sketch it would appear likely to form a most dignified entrance to the city from the railway station, and the whole constitutes what may be justly called a great public improvement. The accompanying illustrations of the proposed improvement are reproduced from the "Sheffield Daily Telegraph."

Royal Academy Lectures.

IN the first of his final series of lectures on sculpture at the Royal Academy, Mr. W. R. Colton spoke strongly in regard to the neglect of public art in this country. Whether he was even correct in saying that "England was a country of great intentions which were rarely carried out" may be questioned. Where are the "great intentions"? Not in connection with the St. Paul's Bridge, the last large

scheme, at all events. The indifference of the public in regard to existing works of art was especially touched upon and in reply to the objection that this climate is unsuitable for open-air sculpture Mr. Colton instanced the sculptur on the Albert Memorial to the contrary, and drew attention especially to the fine quality of the work of Armstead (the reliefs on the north and east sides of the podium) on the Memorial, which is in fact full of interest, though few people seem to be aware of the fact. That is the misfortune in this country; even when a fine thing is done no one seems to be aware of it or to care about it.

In his second lecture Mr. Colton went a little out of the field of sculpture to speak of the neglect of national art in regard to the purchase of pictures, complaining that for the National Gallery we were merely purchasing antiquities at great prices, and that if a picture as fine as anything Titian's were produced now it would probably not find a purchaser; certainly not a Government purchaser. This is a legitimate criticism if we compare the official support of art in this country with the liberal expenditure on pictures and sculpture by the French Government; but in speaking of the National Gallery Mr. Colton seems to forget that it is intended as an historic collection representing as far as possible, all past schools of painting; and that the reason a high price is paid for a typical work by an old master is that the number of such works is limited, and that the artist being long since dead, no more of them can be had. With his onslaught on modern impressionism in painting, and the love of the ugly and grotesque in sculpture, we entirely sympathise. The ideal before the sculptor, he said, must be a fine idea perfectly executed. The question then had to be answered, What was perfect execution, and what made an idea fine or commonplace? The Greeks and Romans thought one thing; the craftsmen of mediæval Italy thought the same; in the greatest period of modern French sculpture there was still the same ideal. But of late there had come over us a straying after a brazen serpent set up in our midst, and brutal expression and execution was called "power." But the domestic

the frivolous, or the grotesque should not find a place in sculpture.

In his concluding lecture Mr. Colton passed in review some of the French work of the seventeenth, eighteenth, and nineteenth centuries, illustrating works by Clodion, Goujon, Houdon, Rude, Carpeaux, and Dalou. The work of the last-named sculptor we thought rather overpraised; he had immense power, but no restraint, and was too fond of violent action. To the list the lecturer added Saint-Gaudens, as a sculptor French by descent, though American by adoption. Mr. Colton pointed out the curious want of any indication of the bodily form under the costume in the portrait of Stevenson, and in a caryatid figure in the Luxembourg; to our thinking the same applies to the remarkable seated figure in the Adams monument, which is a conception of genius, but is badly modelled. Saint-Gaudens is no doubt far away the best sculptor that America has yet produced, but he is greatly overrated; the Shaw monument, of the officer riding with his negro troops, was enthusiastically praised by the lecturer, and has the merit of being a piece of simple sincerity in sculpture; but it is entirely destitute of the quality of style.

Halifax Town-Planning Competition.

THE competition for the best town-planning scheme for the improvement of Halifax, which was decided recently by Professor Adshead as assessor, forms a precedent which might very well be followed in other cases. The competition was not promoted officially, but by the liberality of one person, Mr. Whitley, of Halifax, who offered premiums of one hundred guineas, thirty guineas, and twenty guineas, for the three best schemes presented by architects, solely with the view of bringing the architects to the front in a matter of this kind. We presume that the competition was limited to Halifax architects. The assessor speaks very highly of the general merit of the plans submitted. Those who know Halifax and its hilly situation will imagine that there must have been some special difficulties in evolving a practical town-planning scheme for such a situation, though the peculiarities of the site may also have proved in some ways suggestive. The point to be noted, however, is that an inhabitant of the town has initiated a competition of this kind for the special purpose of bringing forward and premiating the ideas of the architects on the subject. If influential men in other towns would follow his example, the architectural profession would be much strengthened and assisted in their rather one-sided struggle with the city engineers in the preparation of town-planning schemes under the Act.

The Manchester Reference Library.

WE regret to learn that there is an intention on the part of the Manchester Corporation to destroy the fine and dignified building in King Street which was the old Manchester Town Hall, and is now used as a Reference Library, apparently in order to dispose of the site to Lloyd's Bank for the erection of new premises. The façade of the building, with an Ionic colonnade in the centre, stopped at each end by solid wings with an engaged order, is an excellent example of Classic architecture of the modern period; it is, in fact, one of the best pieces of architecture in Manchester, and, as the old Town Hall, should have an historic interest also. The curious part of the matter is that, according to the information we receive from a correspondent, the Corporation are anxious to sell the building for demolition because the proceeds will be an important assistance to the funds required for the scheme of a new art gallery; so that this excellent piece of the older architecture of the city is to be destroyed in the name of Art. This will be the second time that the claims of the art gallery have been made use of to excuse a piece of architectural vandalism. A good many years ago the Corporation, in opposition to strong protest, destroyed the charming anterior colonnaded galleries of the old Royal Institution,

a work of Sir Charles Barry's, in order to get more room in the building for the picture exhibitions then held there. These two galleries opened opposite to each other out of the central hall, each having a row of columns along it, screening off the lower portion of the gallery; the vista through one of the galleries, looking across the central hall to the other one, was one of the most charming interior effects to be seen in any building in England, and it was ruthlessly destroyed for utilitarian reasons, against the protests of many artists and architects. If the Corporation think that deed has been forgotten and condoned, they are mistaken. Apparently they are now about to pursue the same kind of course with another piece of good Classic architecture, and destroy it for utilitarian and commercial reasons. Manchester sets up the claim to being rather an artistic city; but proceedings of this kind do not support the pretension.

The Pictorial Treatment of Architecture.

AT the rooms of the Fine Art Society there is a collection of water-colours by Mr. W. Walcot which are of interest not only for their artistic merit, but for the fact that they deal mostly with architectural subjects. Mr. Walcot has a great eye for effects of colour and composition, and is a master of perspective, which is more than can be said for some painters who handle architecture. His drawings are not however without the defect that we not infrequently see in the treatment of architecture by painters; the buildings being treated too much from the point of view of mere pictorial effect, and their details obscured or evaded in order to tone down the whole into a broad pictorial composition. Now, we neither wish nor expect to see an artist dealing with a building like an architectural draughtsman's perspective; but we do expect to see some semblance of the real detail of a building. In the large view of the Palais de Justice at Brussels, Mr. Walcot has been very successful in combining the claims of architecture and of pictorial effect; it is a fine view of the building, and has at the same time a broad pictorial effect. But we cannot say the same of such a drawing, for instance, as the one called "Notre Dame, Paris" (No. 40), which could only be taken to represent Notre Dame seen through a fog; every bit of detail is gone, it is unrecognisable except for the title in the catalogue. Notre Dame is really a building of exceedingly solid appearance, and very conspicuous detail; it cannot be represented by a mere wash, which seems a very easy and *laissez-faire* way of doing it. Another proclivity of artists in treating buildings is to make new buildings look old, because they are more picturesque so. This is the case with the drawing of "The Bourse, Paris"; the colonnade, with the groups of people dotted about the steps and at the bases of the columns, makes a very good picture, but one cannot recognise it as the Bourse. Brongniart's colonnade is comparatively modern work (it is just a century old), and its columns are still sharp and clean in line; to look at this drawing, one would suppose it was an ancient Roman building rather than a nineteenth-century erection. The Radcliffe at Oxford, and the Pantheon, give more the impression of actuality. "An Egyptian Composition," in which ancient Egyptian architecture is combined with a crowd of figures (or indications of figures) of the period, which furnish great part of the colour element of the picture, though very effective, shows the same oversight that Cattermole and other painters of mediæval scenes have made in regard to mediæval architecture; they forget that when the mediæval people wore those costumes, the buildings were new, not old and weather-stained. The criticism does not apply so strongly to Egyptian scenes, for the Egyptian buildings had so long a life that a crowd in costumes quite ancient to us might be gathered about a building which would be quite ancient to them; but we imagine the reason for it was the dislike to paint buildings too neat and new. It seems to be forgotten sometimes that all ancient buildings were once new. Mr. Walcot shows some interesting sketches (they are hardly more) of reconstructions of ancient buildings; the

exterior of the Calidarium of the Baths of Caracalla is one, with a brilliant red on the podium; but it is only a general effect, too slightly indicated to be called a restoration. "The Basilica of Constantine in the Early Middle Ages" is a drawing of more force and reality, and is very interesting. An impressive indication of a picture is given in "A Tragedy of Sophocles performed before the Emperor Hadrian," a view from the interior of the theatre, with the scene closed at the top by the open colonnade surrounding the auditorium; it is a very brilliant effect, but only an effect; not a detail either of architecture or personages can be made out.

The tendency with some very clever painters of the present day to treat architectural subjects, great and celebrated buildings, as mere materials for a kind of washed-out or silhouette effect, is to be regretted, because it is not making the best use of architecture as a material for pictures, and it is giving a false idea of the real effect of the buildings. Piranesi and Prout succeeded in making exceedingly fine and effective pictures out of architectural subjects, pictures which are at the same time among the finest and most forcible representations of architecture. And what they did can be done again.

Ventilation of Factories.

IT is complained that the Factories and Workshops Act, 1911, is seriously retrograde in respect to ventilation.

Dr. Arthur Ransome contends that in the consequent "Regulations as to Humidity and Ventilation in Cotton Cloth Factories," which have just been issued by Mr. McKenna, those relating to ventilation can but tend to deterioration in the health of the operatives. The standard of purity of the air, he points out, is greatly reduced. In the regulations previously in force, the amount of carbon dioxide allowed per 10,000 of air was only five volumes in the case of humid sheds, and the same standard was recommended by the then Home Office for dry sheds also. The new regulation enacts, however, that in humid sheds the proportion of carbon dioxide shall not exceed eight, and in dry sheds eleven parts by volume per 10,000 of air in excess of the proportion in the outside air at the time. The former conditions, which had obtained since 1897, resulted in a marked improvement in the health of the operatives; but Dr. Ransome greatly fears that "the new and degraded standard will lead to more ill-health, to respiratory disease, and especially to an increase in the number of consumptives." As Dr. Ransome was a member of the Home Office Committee which, in 1896-7, recommended the standard that is to be superseded, he has doubtless good grounds for his note of warning, to which we trust due attention will be paid. It would be interesting to know the reasons for the retrograde regulation, which, in the absence of explanation, seems to lower the standard without rhyme or reason.

WHAT IS WANTED IN THE BUILDING TRADES.

VIEWS OF MR. F. L. DOVE, L.C.C.

INTERVIEWED by a representative of this Journal on the subject of the articles that have been published under the above heading in our issues of January 10th, 17th, and 24th, Mr. Frederick L. Dove, L.C.C., the eminent contractor, said: "I have read your articles with a great deal of interest, but I cannot see how the suggestions they contain are to be carried out. You cannot prevent a man from selecting any builder he chooses to erect a building for him, nor do I think you would be able to do so, particularly in the present temper of society. That building work be provided cheaply appears to be the be-all and end-all of the majority of present-day clients. Take, for instance, church building, which constitutes an important branch of the work of my firm—indeed, I doubt whether scarcely any other firm

in the kingdom has carried out more of this particular class of work than my own.

"We now find that the conditions are totally different from what they were some years ago. Formerly, after examination of the estimate by the architect or quantity surveyor, the work was not infrequently placed directly with a firm—or, at the most, three or four firms, known to be experts, were invited to tender. Now all sorts of people—builders, builders' agents, or anybody else—are indiscriminately invited to tender; and, provided it is cheap, the committee care not two straws who carries it out, no matter how absurd the tender may be, and the architect is expected to be rather a watch-dog than an artist. I am reminded of a saying of Ewan Christian, one of the most delightful gentlemen it was ever my privilege to know or work for: 'The architect is not a policeman, and I want a man upon whom I can depend to carry out my work.'"

"This demand for cheap work," continued Mr. Dove, "has led to the growth of a purely commercial type of builder, and those of the old school who really enter into the spirit of the designs they are carrying out are getting fewer every year. This tendency, of course, has been greatly accentuated by the modern system of sub-contracting which now prevails to such a large extent, due in the first instance to certain architects (not of the first rank) obtaining sub-contracts not merely for special items such as mosaics, carving, etc., but for the stonework, brickwork, joinery, floors, etc., the result being that the man who took an interest and a pride in his work, and who employed highly skilled and highly paid workmen, loses that interest when he finds his work no better appreciated than the rubbish which is turned out by so-called building firms whose main stock-in-trade may consist of a roomful of telephones.

"It is somewhat remarkable that, in a matter of so substantial a character as building construction, the public adopt the exactly contrary course to that of everyday life. No man in his senses expects to get a perfectly made, well-fitting suit of clothes for the same price as he would pay if he went to an East End ready-made slop shop, and yet this is the course generally adopted when inviting tenders for buildings; consequently competition then becomes a farce.

"With regard to your scheme for preventing a man calling himself a builder unless he is equipped with a knowledge of materials, construction, and so forth (which, of course, can only be gained by his learning the practical and technical part of the work), however desirable this may be (and I for one am in earnest sympathy with it), I do not see much chance of this change being effected unless the public can be brought to differentiate between good and bad work. In the matter of public taste and appreciation of good quality, I think a distinct depreciation has taken place. Let us take furniture for instance. The appreciation of good furniture to-day is nothing like it was thirty or forty or even one hundred years ago. Everything that stands in the way of cheapness must be sacrificed. I do not think that your proposal could be materialised by legislation. It does not seem possible for legislation to decree that if Mr. A wants a building or an alteration to be carried out he must employ X, Y, or Z, or that because W has not qualified he should not be allowed to do the work. So long as a man complies with regulations, Acts of Parliament, and by-laws, etc., in erecting his building, it appears to be difficult for the Legislature to step in. The same remark applies to public work. People who are specially interested in building—such as members of a local council, etc.—are only concerned to get the work knocked off at the lowest possible cost. In view of this fact, I think your article have tended rather towards an ideal state, which, to me seems next to impossible to bring about. So far as our own apprentices are concerned, we have always tried to inculcate the doctrine which you preach, and to get them to appreciate their work and to take a pride and an intelligent interest in it; and on the whole we have, I think, been fairly successful in so doing."

Interior looking West.

THE LADY CHAPEL OF LIVERPOOL

Interior looking East.

AL. G. GILBERT SCOTT, ARCHITECT.

THE ERECTION OF LIVERPOOL CATHEDRAL.—I.

BY ARTHUR GREEN.

The first instalment is here given of a practical account of the erection of Liverpool Cathedral, describing in detail exactly those items in which the architect and the builder are most interested, the article having been written by one who is acquainted with the work at first hand. The concluding portion will appear next week, with further illustrations.

It is just upon eight years since a start was made to build a cathedral church for Liverpool. St. James's Mount was, after much controversy, selected as the site; Mr. G. Gilbert Scott being the chosen architect, while with him was associated the late Mr. G. F. Bodley.

To ensure a solid foundation, borings were taken to ascertain the depth that would have to be sunk to get to the rock.

The cemetery adjoining, and the ground half-way across the site selected for the Cathedral, had been worked as a stone quarry, and after the stone had been taken away the Mount was made up of loose earth, the consequence being that while half the site is virgin rock, the other half is soft soil. Taking a line

vestries, etc., was let to Messrs. Morrison and Sons, builders, Wavertree, Liverpool, in September, 1904, and was done on a schedule of prices, the measuring surveyors appointed being Messrs. Northcroft, Neighbour, and Nicholson, of London. The system adopted in the foundation generally has been to carry down, where concentrated loads occur, large concrete piers, which rest upon the rock; the intermediate parts, where the load is considerably less, and is more evenly distributed, being carried on concrete arches turned from pier to pier. Where the rock is near the surface, the walls rest upon it throughout their length; but even in this case it was necessary to excavate to a considerable depth.

On May 10th, 1906, Messrs. Morrison and Sons, the foundation contractors, were successful in obtaining the work of building the superstructure. It will be remembered that they were the builders of the Rylands Library, Manchester. Work was promptly begun, the Lady Chapel, which was proposed to be completed in four years, receiving most attention. The choir, now in course of erection, is composed of three bays, each 41 ft. centre to centre of the arcade piers, and the sanctuary, 11 ft. 3 in., the width between the arcade walls being 47 ft. The piers of the choir are continued solid across the aisles (which are 13 ft. 6 in. wide), forming a continuation of the outer buttresses. The wall, 5 ft. wide, is pierced by low

LIVERPOOL CATHEDRAL: GENERAL VIEW FROM HOPE STREET (June 22nd, 1911). G. GILBERT SCOTT, ARCHITECT.

rough the centre of the site, there is a sheer fall of 28 ft., which slopes away to considerable depth at the edge of the site. The first piece of building done was that of the foundation work for the lower pier on the south side of the Cathedral. The contract for this work was let to Messrs. Thornton and Sons, builders, Liverpool, and was in preparation for the laying of the foundation stone. This preliminary work having been completed, a large semicircular stand was built, to hold 7,000 people, and on July 4th, 1904, the late King Edward, accompanied by Queen Alexandra, laid the foundation stone. The work of putting in the foundation for the choir, towers, chapter-house,

the first 10 ft. or so being very loose, and having to be removed before the foundation could be put in. By far the largest excavations occur under the north tower, which stands on the extreme edge of the site towards the cemetery. At this point there are four concrete piers, two of them measuring 40 ft. by 28 ft. at their base, and 50 ft. deep, and two 28 ft. square and 40 ft. deep. The foundations along the north side averaged, including the chapter-house, 40 ft. deep. The foundations in every case were taken into the rock. The surfaces upon which stand the various piers, etc., were made level, grooves being cut on the bed and vertical sides to give a key to the concrete. The work of putting in the foundations was completed in fifteen months.

arches to form a passage along the aisles. Each bay in the aisle is in consequence shut off from the other. The barrel vault is divided into panels by ribs, springing at the height of 55 ft. from the floor, the apex of the barrel just clearing the choir aisle windows, and the vault carrying the triforium gallery. There are three windows in each aisle of the choir, the sill being 41 ft. from the floor. Each window is of two 6 ft. 10 $\frac{3}{4}$ in. lights, with a simple form of tracery. On the jambs, inside and out, are carved figures with canopies and crocketed pinnacles over. A carved string runs along the aisle walls inside, and across the low arches, this being filled with winged figures and foliage. A narrow walking-way is tunnelled in the thickness of the

LIVERPOOL CATHEDRAL: THE VAULTING OF THE LADY CHAPEL, FROM ABOVE.

aisle wall (the wall being 6 ft. 3 in. wide), which connects the circular stair (the entrance to the stairs is on the Lady Chapel gallery) and the organ chamber at the west end of the south choir aisle. At the east end the choir aisles have a low barrel vault, carrying a floor above. The vault is carried on a carved cornice, and has a carving course each side of the ridge rib of the vault. Each aisle is lighted by a rose window in the east wall. A similar vault is at the west end of the aisles, the floor above being the organ floor. An ambulatory outside the main east wall connects the two choir aisles, and is lighted by four two-light windows.

The ceiling is a barrel vault, the ribs of the vault being transverse and diagonal, with carved bosses at each intersection of the ribs. The roof over the ambulatory is composed of concrete, covered with asphalt. A low arcade in the east wall of the ambulatory gives access to the bishop's, dean's, and canon's vestries, and at each end of the ambulatory are corbelled-out balconies, with tracery balustrade. The floor is 2 ft. 6 in. below the level of the choir aisle. The arcade piers in the choir are 55 ft. 7½ in. from the floor to the cap, from which spring the arcade arches. The rise of the arch is 20 ft., and the width of the arcade wall 6 ft. 4½ in. The front part of the arcade pier continues past the springing of the arcade arches, forming a vaulting shaft to the cap, which is 84 ft. 6 in. from the floor level. The vaulting springers are immediately above. The vault is quadripartite. There are four main transverse arches across the choir, fully moulded, and 5 ft. wide. The bays of the choir are divided for vaulting, a wall being built across the triforium to form abutment to a minor transverse rib crossing the choir. The smaller bay is then formed by diagonal ribs. The height to the apex of the vault is 116 ft. from the floor level. At the time of writing, a start has been made to fill in the ribs and sheeting forming this vault. The triforium is 82 ft. 6 in. from the floor, the width being the same as the aisle below—13 ft. 6 in.

Each bay is covered with a barrel vault, divided into panels by ribs. The back of the vault will be treated with concrete, with asphalt over to form the roof. Between the bays, and overlooking the choir, the triforium will have carved tracery screens, from pier to pier of triforium arcades. The east window sill is 46 ft. from the floor level. The window takes nearly the whole of the east end from the sill, being 36 ft. wide from jamb to jamb, and from sill to apex of tracery 76 ft. in height. It is divided into four lights by a large central pier, and two small mullions. On the central pier are carved figures with canopies, in the apex of the window is a large circle 11 ft. 6 in. in diameter with cusps. Under the window there will be a red stone reredos. The organ will be on each side of the choir,

in the two western bays of the choir aisle. The roof of the choir is carried on walls built on the back of the four large transverse arches, and is of reinforced concrete covered with copper.

The outside of the choir has large buttresses, with plinth courses and weatherings. The faces of the buttresses are battered, and terminate in weathered gables, with pedestals on which are angels. On each side of the angels are pinnacles. The outside sills of the choir aisle windows are carried on a low arcade. Over the windows is a covered walking way, with arcade and tracery balustrade. At the east end of the north and south choir aisles rise square towers, which are surmounted by dwarf stone spires, the tops of which are 150 ft. from the floor level. The two towers are connected by a wall.

LIVERPOOL CATHEDRAL: VAULTING OF LADY CHAPEL, FROM BELOW.

LIVERPOOL CATHEDRAL: VIEW OF EAST END IN COURSE OF ERECTION.

ing-way immediately above the east window. Access to the walking-way and towers is by means of a spiral stair in the main east buttresses; a doorway through the east gable giving access to the space between the back of the choir vaulting and the roof of the choir.

On July 17th, 1906, the foundation-stone of the chapter-house was laid by H.R.H. the Duke of Connaught, with full masonic ritual. £10,000 has been provided by the Freemasons of the province of West Lancashire for building the chapter-house, in memory of the first Earl of Lathom. The chapter-house is on the north-east corner of the Cathedral, and is on plan an octagon rising from a square base; it is lighted by four two-light tracery windows, the sill of the windows being 13 ft. 3 in. from the floor level. On the mullions of the windows are four carved figures, with canopies.

A stone seat runs round the building, also a moulded and carved string immediately below the sill of the windows. The space between the seat and the string is 9 ft. 6 in., to be panelled in oak. From the blank sides springs the vaulting, which forms a square, then turns into a circle. The vaulting carries a walking-way, about the same level as the walking-way outside. Both inner and outer walking-ways have tracery balustrades. On the four blank sides inside are large coats-of-arms carved in stone. The turret on the north-east corner encloses a spiral stair, which leads to the walking-ways. The entrance to the stair is from the inside of the chapter-house. The floor is 2 ft. 6 in. above the nave floor level, and is to be paved with marble. Below the chapter-house, and on the level of the lower vestries, is the song school. The roof of the chapter-house will be of

reinforced concrete, covered with copper.

The vestries are on two floors. The lower vestries are at the same level as the Lady Chapel, and the upper vestries are 2 ft. 6 in. below the nave floor level. On the lower level there are several small vestries. In the centre is a large lobby, from which a doorway gives access to the courtyard. In the ceiling of the lobby are two large English oak moulded beams, which carry the floor above. A passage-way, with oak-panelled ceiling, connects the Lady Chapel and the song school. This passage gives access also to the vestries. There is a low arcade of three arches at the entrance to the lobby. The upper vestries are for bishops, deans, and canons. These vestries also have large English oak moulded beams in the ceilings, which carry the roof above. On three sides the vestries are panelled in English oak. On the fourth side are

windows. All the doors are of English oak. On the outside wall of the vestries are six buttresses, 4 ft. wide, finished at the top with weathered gables. Large blocks of stone are placed at the top of the buttresses, on which will be carved groups of figures. Between the buttresses and lighting the lower vestries are a series of three-light square-headed windows without cusps. The windows lighting the upper vestries are of four lights, with tracery heads. They are deeply recessed, with weathered sill, and having a curtain arch outside. The height from the courtyard to the top of the parapet is 25 ft. The roofs of the vestries are covered with copper.

The stones used for the building of the Cathedral are local red sandstones, from the quarries at Woolton, Runcorn, and Rainhill. The Woolton stone is used for all work exposed to the weather. The three stones are used mixed together inside the building, Woolton or Runcorn being used where heavy weights occur. Throughout the building the thickness of the mortar between the beds and joints of the stones is $\frac{1}{2}$ in. The advantage of using half-inch beds is, that a stone can be put on to an inch of mortar and driven down until the bed is half-inch, thus ensuring that the stone shall be solidly bedded. With thin beds and moderately large stones, it is almost impossible to make them solid, as the sandstone

quickly absorbs the moisture in the mortar, and consequently a solid bed is not assured. With half-inch joints, moreover, the cement grout has room to run in and fill the joint solidly. With tight joints the grout cannot fill the joints. The whole of the joints throughout are arris-joggled. The mortar is composed of Clitheroe lime and ashes, ground in a mill. All the joints are raked out as the work proceeds, and are pointed at completion with grey mortar, which brings out the lines of construction very clearly. The stone used for steps and landings is red Wilderness stone from the Forest of Dean. The walls are filled in between the stones with Ravenhead bricks, from St. Helens.

The plant and scaffolding are not without interest. At the west end of the site are three frame saws for sawing stone. A five-ton crane travels the whole length of the frames, and unloads the blocks of stone as they are brought to the site by teams of horses on lorries. This crane also lifts the blocks of stone on to the trucks which pass under the saws to be cut to the required sizes. This being done, the crane again lifts out the sawn stone, and places it ready for the four-ton travelling crane, which runs down the centre of the site as far as the east wall of the Cathedral, to distribute it to the masons, to be cut into shape for the various parts of the building. A long line

of masons' sheds runs parallel to this track, in which about 80 masons are busily engaged shaping the stones into ashlar, quoins, jambs, archstones, tracery, canopies, etc. On an average about 100 masons are engaged; the remaining 20 are working out on the building. There is a board on which to set out the work the full size required, and on which the zinc templates are made for the masons to shape their stones by. This board takes up the whole of a shed measuring 50 ft. by 50 ft. On the site are six derrick cranes, one at the east end, one on the north side, two at the west end, and two at the south side. These cranes are 130 ft. high, built on timber cages, having iron lattice jibs, varying from 70 ft. to 100 ft. long. They command the whole of the building, and lift up the worked stone to the mason fixer, who then builds it permanently into the place appointed for it. The whole of the plant is driven by electricity, the power being taken from the corporation mains. The scaffolds are built mainly of 12 in. by 12 in. pitch-pine logs, varying in length from 20 ft. to 60 ft. The logs not only form the scaffold, but are so arranged that they act as supports to the centres on which the arcade arches were built, continuing upwards to support the centres on which the transverse arches and vaulting are carried. The scaffold outside the east window is carried on two large steel girders bolted together, and let into the buttress on each side of the east window—just clear of the ambulatory roof. Ample messrooms are provided for the workmen. A large pavilion, which will accommodate 200 men, is built on the site, in which the men's services are held on each Tuesday, during their dinner-hour. A lay reader works amongst the men, and on the first Tuesday in each year since the Lady Chapel was opened the Lord Bishop of Liverpool has addressed the workmen in the Lady Chapel. The average number of workmen employed for the Cathedral is about 220.

The Lady Chapel is illustrated on the Centre Plate in this issue.

The design of the Cathedral was amended a little over 12 months ago, and in place of the two transept towers there is to be one large central tower, rising to a height of 280 ft. The transepts remain, and will act as buttresses to the east side of the central tower. Two other transepts will be built to buttress the west side of the central tower, as the work is extended. The amendment of the design is entirely Mr. Scott's own idea and has met with the approval of the committee. The committee require £70,000 to complete the choir and the eastern transepts. As regards the style of architecture, Mr. W. Horsfield may be quoted. He says: "As to the style, it is difficult to speak. Gothic in the large sense of the word—but not to be confounded with any particular one of the tabulated styles. It shows familiarity with and study of ancient forms, but it is no diatessaron of undigested parts collected at haphazard fancy and flung together in the mode of the Gothic Revival and spoken of as of this or that particular period or century. It is modern of the twentieth century—of to-day—thoroughly digested, and has been tied by no style, and an example of living modern architecture as applied to a religious problem—religion, from whom the art of architecture had its being, for whom it was invented and developed. Modern method facing and solving an ancient problem."

(To be concluded.)

LIVERPOOL CATHEDRAL: CHOIR AND CHOIR AISLE LOOKING EAST.

THE PLANNING AND DEVELOPMENT OF A GARDEN SUBURB.*

BY MICHAEL BUNNEY, A.R.I.B.A.

It has been complained that, generally speaking, papers on town planning tend to overmuch theorising. The paper here printed, while paying due attention to the elucidation of principles, is rather exceptional in its happy blending of theory and practice, and it therefore possesses unusual value from the professional point of view.

THE Victorian Era was remarkable for many social movements, and the expansion which took place in towns was extraordinary, not only for its great extent, but in the fact that practically the whole of this expansion was, so far as its planning was concerned, haphazard, and without direction. Vast tracts of land around all our most important cities were covered within the last seventy years with thousands upon thousands of houses, most of them on roads laid out with little or no regard either to the general interests of the town or to the particular interests of the people who were to live in the houses.

The Beginnings of Town Development.

In the earlier part of this period of expansion the ignorance or neglect of the most primitive principles of public health were too often a strong element in the methods employed, and the consequent reaction upon the health and on the social and material status of the inhabitants, and the ill-regulated and insanitary conditions which prevailed, drew the attention of sanitary reformers. This resulted in the passing of the Public Health Act and sundry Building Acts, and upon these laws and the succeeding extensive passing of by-laws regulating building operations and street-making, the bulk of town development has, until recent years, depended.

Admirable as much of this law-making was from a sanitary point of view—and the early by-laws and regulations as to streets did make the work of local government simple and orderly—they still set a standard too inelastic and unsympathetic—their fault lay in their being too well framed, too little wanting constant amendment, that helpful hand to progress. The result has been that the standard of the 'seventies remains to all intents and purposes the standard of to-day.

It was characteristic perhaps of our national methods that we should have begun our reform at the bottom by setting right the details, and setting them right presumably for all time, before we understood or even conceived of the governing principles.

The Revival in Domestic Work.

Side by side with this municipal direction some wider public interest was being aroused—an undefined desire arose to improve the dreary monotony of our suburbs—domestic architecture was undergoing a change which is destined to stamp our time with a revival in building second to none in our architectural history. The mind of the house-designer was grappling with the application of traditional methods to the small living house.

Mr. Norman Shaw began by handling the problem of the small house on entirely new lines—he broke away from the typical plan, plotting, and general arrangement of the stucco villa, and at Bedford Park created a piece of housing reform in its widest sense, the influence of which on this movement is being, I am afraid,

somewhat lost sight of. Excellence and practicability of plan, the use of simple and local materials undisguised under coats of paint and stucco, and carefully thought out and balanced colour schemes,—these were some of the qualities successfully utilised at Bedford Park.

The speculative builder could not afford to ignore them, and imitated them as best he could—not very well, it must be admitted—but his worst effort was a thing as unlike the old accepted idea of the small house as is Willesden from Gidea Park.

The result upon public taste was instant. Beside this, and synchronising with it, was the rapid advance in sanitation, both public and domestic. While Norman Shaw was forming a new school of architectural thought, Rogers Field was working out the modern sanitary scheme from the nightmares of early Victorian times, and the giants of our main drainage and bacteriological systems were making the scientific treatment of city waste a thing assured.

Thus while every detail of the healthful housing of the people was advancing under the pressure of professional application, and whilst the restless thinking of the social reformer was being slowly focussed upon some great principle which he could apply to co-ordinate the whole for a real advance, the general movement in town planning was to come after and not before the elaboration of the parts that go to make it possible.

Our practical mind is shy of the theoretical side of any question, and it was presumably on this account that the well-worked-out theories of the German town planners and their practical application extending back for some years escaped attention until the issue of Mr. Horsfall's book in 1904—Mr. Ebenezer Howard, it is true, had previously issued his well-known "Garden Cities of To-morrow," an inspiring, yet, in the main, theoretical treatise. Mr. Horsfall, however, clearly showed how successful German municipalities had been in applying their town planning powers, and in declining to allow urban extensions to be carried out without some substantial measure of agreement as to how they were not only to be planned, but also their probable effect on public as opposed to private interests.

Bournville, Port Sunlight, Letchworth.

Meanwhile, the pioneer efforts at Bournville, Port Sunlight, and Letchworth drew attention to the possibilities inherent in the new movement.

Letchworth.—Rigidly based, so far as natural features and accidents of purchase allowed, on Howard's theories—the garden city self-contained and unattached, supposed to provide for every class of resident with its own industries and industrial population, eventually fully and already partially self-governing—supplying all its own municipal services—the few of its dwellers who happen to be London daily workers are purely accidental, and not necessary to its civic completeness.

Port Sunlight.—A housing department for one particular firm's own employees,

living under the constant and semi-paternal care of the owners, who retain their interest and exercise effective control—philanthropic, purely in the sense that it cannot pay a commercial return except in the added efficiency of the worker—part of a settled policy of housing, of high wages, of facilities for recreation, and the putting into practice of the finest principles of industrialism, and, intentionally or unintentionally, a brilliant piece of advertising.

Bournville.—Also inspired by a desire to better the lives of the workpeople of the promoting firm—governed by trustees independent more or less of the promoting firm, and the accommodation not wholly restricted, as at Port Sunlight, to workers for the firm. The result is much less control, a greater approximation to normal conditions of social life, and therefore in every way a more practical experiment.

All these three types were in the nature of propagandist work. They were examples set up for a dual purpose, the direct one of teaching an object-lesson in housing reform and the indirect one of demonstrating the value of town planning control. Excellently, however, as they served these purposes, enterprises on these lines are bound to be isolated, insufficient in number to do more than point the way, and in one at least of the three types so purely philanthropic in character as to go beyond the regions of business altogether.

Business Basis Essential.

Now we may be specially sympathetic as a nation towards experiments for bettering the people, even at costs which seem disproportionate to the good results obtained; but, after all, no reform or progressive movement of this nature is likely to take firm hold until it can prove its possibilities for being worked on a business basis; by that I mean a basis that will return at least a moderate dividend on invested money and a fair remuneration to those engaged in doing the work.

For the aims of the movement are wider than the purely theoretical ones confined to such abstract principles of town planning as the city development plan, city improvements, architecture, and its relation to civic ornamentation, treatment of open spaces, etc. These matters, of course, have their place and function even in the most practical considerations of suburb development, but the movement finally depends on the business issues of cheap, attractive, and better houses, of their relation in numbers to the given area, of the economies which a more sensible treatment of the road-making problem will make possible, and on the raising, not only of the standard of comfort, but of the standard of taste that the town planning movement will push forward to an early and sure realisation. . . . Certainly there is nothing in which people have shown a greater aptitude for education during the last ten years than in the hygienic way of living, and this it is the present aim of the town planner first and foremost to foster.

Garden City and Garden Suburb.

Many apply the title "Garden City" to garden suburbs, and it would be well to clear up this little point before we go further into the details of garden suburb development. The term garden city involves an element that shall be self-contained; it describes a community independent, yet interdependent.

*Extracts from a paper read before the Institute of Sanitary Engineers, January 8th.

with its own sources of livelihood, factories, industries, and industrial community, common government, common ownership of public utilities—in fact, a town in itself. To all intents and purposes this is what Letchworth aspires to be and is rapidly becoming. On the other hand, the suburb is what the word implies: it is secondary to and an appanage of the city, and may vary in size from a whole administrative area of local government like, say, Croydon, to a congeries of a few streets like some of the small garden suburbs at Harborne, near Birmingham, or those in the outskirts of Warrington. The Hampstead Garden Suburb, for instance, is but a small portion of the Hendon district; it uses all the municipal services supplied by the Council, and takes its part fully in the local life of the whole. But even the suburb can have its civic centre, subsidiary, it is true, to the town centre, yet still a replica in miniature of the greater gathering-place of social and commercial activities. To this civic centre will be brought such public institutions as may be convenient—the places of worship, possibly the schools, clubs, and meeting places for social, recreational, and educative means. But the garden suburb will be primarily residential.

Forming a Garden Suburb.

Let us suppose that the estate we propose to convert into a garden suburb is the property of a single owner or an association of owners syndicated for the purpose, with capital available or arranged for, and a competent surveying staff already in the saddle. Some advice will have presumably been taken on broad lines as to the suitability of the land for the purpose, and as to the financial possibilities of the scheme. The first practical piece of work to be done will be the collection of such data as will enable a properly planned scheme to be prepared, and for this purpose the R.I.B.A. have already drawn up valuable suggestions.

A fully detailed survey must be made. Not only is it necessary to measure and plot the whole of the land, but levels must be shown by means of contour lines at least at every 10 ft., and preferably at every 5 ft. All physical features and trees, hedges, water-courses carefully plotted, and notes made of such a nature that the fullest possible information will be readily available to the site planner. Information must be collected and analysed as to the social and economic condition of the population likely to be attracted, as to the history of the development of the adjacent or related developments; as to buildings and other material survivals, or traditional associations worthy of preservation as tending to carry on the individuality of the district, and, finally, a complete record of social, educational, and municipal services available. Much of this information can be made available by means of diagrams or maps specially annotated and coloured; in fact, in the case of small estates, all these data can be placed upon the survey plan, which will be found most useful if worked out to the scale of 25 in. Ordnance maps.

On most estates also there are special views or standpoints, the character of which is worth preserving, and it is advisable for this purpose to have photographs taken recording these.

Preparing the Development Plan.

As soon as this information is collected, analysed, and reduced to summary and plan, two methods of dealing with

the next steps present themselves. The first is to employ the services of a town planner, be he architect or surveyor, or both, of some repute, and capable to prepare a satisfactory development plan under the direct instructions of the promoters. Needless to say, this method wholly depends for its success on the capabilities of the planner.

The second method, which, in the present stages of the movement, the author considers the better, is to promote an open or limited competition. For this purpose some well-known town planner, preferably again an architect, should be appointed to act as judge or assessor, and be empowered to draw up a schedule of conditions under which the competition is to be carried through in consultation with the promoters and their professional adviser.

The method of open competition, notwithstanding some faults, has the great merit of unearthing latent talent, and incidentally widens the area of interest and experience among the competitors, and thus helps generally to promote the movement. It also provides an object-lesson to the public, and a means of education, especially if the designs are publicly exhibited, with the opportunities afforded by the public exhibition for local conferences and lectures upon the principles involved. All this publicity is invaluable to the promoters in advertising the new development and arousing interest among house-hunters and others, who may eventually be attracted to the estate for residential purposes.

The Act confers the power to suspend, as far as may be necessary for the proper carrying out of the scheme, any statutory enactments, by-laws, regulations, or other provisions, under whatever authority made, which are in operation in the area included in the scheme, and will enable, therefore, the adoption of an economical construction of roads of varying types suited to the requirements of the traffic likely to pass over them, and of the type of houses abutting upon them.

Roadmaking.

By-law roads of a uniform width of 40 ft. or 50 ft., with expensive formation with elaborately paved footpaths, kerbed and channelled irrespective of the work they have to do, and their construction regulated more by the eventual cost of maintenance than by the effect on development of their heavy initial cost—these have been one of the material causes of the methods of development we all deplore, with its skimpy-fronted plots and large number of houses to the acre. The small house or cottage builder has been forced to cover this initial road-making cost by cutting down his plots and the accommodation of his houses, and to crowd the land to its utmost extent. Under the Act there is little doubt that a very great modification in roadmaking will be allowed. In fact, the roads—some of them were carriage drives, which have stood the test of three years' traffic at the Hampstead Garden Suburb, and were constructed under the special Act of Parliament obtained in 1906 by the Hampstead Garden Suburb Trust—will be taken as bases for further work, and will in all probability be sanctioned by the Local Government Board.

Where in residential districts the only traffic to be provided for is the tradesman's cart and the occasional taxi-cab, a well-made carriage-way of 16 ft. or even 13 ft. in width will be found ample. The footway can even be dispensed with altogether where the larger drive is

provided, and the total road width of 26 ft. made up by grass margins; at any rate, a 26 ft. road, 16 ft. carriage-way, with two footpaths of 5 ft. each, should be ample for any purely residential traffic of this kind. Two provisions alone must follow, and be insisted on when this method of roadmaking is adopted, and these are that the land so saved *must* not be clipped from the plots, and the building lines *must* be kept at least 50 ft. or 60 ft. apart.

But this does not end the advantages which a saving on the cost of roadmaking allows; greater frontages can be given with the consequent opportunities for the more sensible planning of the houses, for greater spaces all round the houses, and for a general resultant effect of openness and light and air.

Method of Plotting.

So much for roadmaking. Next in importance comes the method to be adopted in respect of plotting, the fixing of the building area in relation to the size and aspect of the plot, and the grouping of the houses. The site planner will to a large extent have borne this point in mind in making his plan. He will have arranged for buildings to form road terminals, and thus close what might otherwise form a too extended and monotonous view, for some treatment of studied arrangement when awkward corners had to be turned, and round his open spaces will have suggested a plotting which will secure to the maximum number of houses some outlook upon open ground. Trees and hedges, again, will have influenced the plotting, so that as many as possible of these physical features should be preserved from destruction, and the exigencies of varying levels will not have been neglected.

If the estate managers are in a position to plan out the plotting from the commencement, and substantially adhere to this once it is decided on, as may be the case on estates, or portions of estates, wholly dealt with by the building owners—such, for instance, as the Co-partnership Tenants' Societies—a prearranged scheme not only of grouping out of the types of architecture to be allowed, the materials to be used, roof and eaves levels, etc., can be insisted on. This is not quite so easily done where the owner proposes to dispose of plots as and when the demand comes along, though even in this case a scheme of grouping, etc., can be prearranged to a certain extent. Much diplomacy and tact, however, are required to get it carried through successfully and willingly accepted by plot-holders; though it is surprising how far a little suggestive conversation, a patient explanation of the ideals aimed at by the promoters, goes in bringing round a stubborn inquirer who *will* have his house his castle, and that as different from his neighbours' as it can by hook or crook be made in size, plan, elevation, materials, and position. Where a plotting plan can be made and adhered to, it is best drawn out to a scale of 1/500, or 41.66 ft. to the inch, as on this scale can be shown every detail which must be made clear to the plot purchaser, the particulars of the type of house and the materials, information as to any prearranged form of boundary treatment, fencing or hedging, the positions of the soil and surface-water sewer connections, of the water-ferrules and the gas and electric connections; and if the roadmaking charges—that is to say, the estimated cost which each plot-holder will be liable for on the local authority taking over the roads—

can be pooled over the whole estate and allocated definitely to each plot, and the amount duly marked on the plan, many disputes and recriminations with the sales department are thereby avoided.

Points in Plotting.

A successful scheme of plotting must include an adequate provision of houses grouped together, either semi-detached or in blocks of up to six in number. Though most of us prefer to live in a detached house, there is no question but that, from an architectural point of view, an estate covered entirely or principally with detached houses, especially if these be small in size, is a difficult one to treat successfully. The attached house, if a proper archway or back road be provided for access to the back gardens, or for purposes of drainage, has many advantages; it is warm, it is economical to build, and it requires less frontage, thereby releasing more land for open spaces—in fact, the arrangements of plots and building areas to produce an ordered result must be governed by other considerations than that of obtaining the maximum number of selling plots. The town planner must foresee what effect the general mass of his buildings will produce, and vary the street picture by judicious settings forward or backward of his building lines. He must change now and then the spacing of his building areas, and in long roads definitely group the houses in compartments so as to confine the street effect to no more than the eye can comfortably take in. In short, plotting for a garden suburb becomes subsidiary to and bears constant relation to the arrangement of the buildings, and the difficulty of the problem lies in the blending of an economical and practicable plot plan with the architectural grouping of the houses to be built upon it. It is a problem that must be faced throughout, at every road junction, whenever the vista or the terminal are desired, at curves, round greens and squares, where buildings are to abut on large open spaces, and where fine trees or hedges must at all costs be preserved and made to harmonise with the scheme.

The treatment of boundaries also requires consideration at an early stage, and a comprehensive scheme for this worked out and enforced—simple treatments of posts and chains, with a hedge behind of privet, yew, or holly, or wide-mesh oak trellis, with openings 6 in. square or so, and with Penzance briars, or cheap climbing roses tied to the trellis, or again the cheery Rosa Rugosa behind a low brick curb wall—all are really less expensive than the dwarf wall, its stone coping and cast-iron rails, or the park pale fence so dear to the speculative builder.

Building Regulations.

As soon as the roads are in hand, and the plot, plan, and building areas decided upon, building operations will begin, and here it is essential that proper control be exercised from the start.

Building regulations of a much more comprehensive character than those usually tucked away in the recesses of building agreements are required. They should be framed in such a way as to disarm the prejudice and quiet the alarms of the enquirer, for the man, especially the small man, who is about to build a house is a nervous individual.

The author had found little or no difficulty in tuning up materials and building construction to a level, generally speaking, well above that of the usual by-law requirements, and such items as

1½ in. grooved and tongued floor-boards, and oak or teak window sills, have been cheerfully agreed to even by the usual type of speculative builder. At the same time, recommendations to consider that most buildings on a garden suburb will be seen all round and should be treated

accordingly, and with the minimum of unsightly outbuilding behind, suggestions as to type and colour of materials required in given areas, as well as the discouragement of the use of materials in imitation of others, have been received and acted on with evident appreciation.

REGINALD T. LONGDEN, ARCHITECT.

This block of offices, now in course of erection on a site opposite the King's Hall, Stoke-on-Trent, is to be styled "St. George's Chambers." The outer facings are of brick, with dressings of Alderley stone, and the roof is of green Westmorland slates. The three lower floors will be fitted as offices, and the upper two as warehouses. The architect is Mr. Reginald T. Longden, of Stoke, Burslem, and Leek, and the general contractors are Messrs. Willcock and Co., of Wolverhampton.

REGISTRATION OF ARCHITECTS: THE TRANSVAAL BILL.

In view of the fact that at present the Institutes of Architects in South Africa are considering a Draft Bill for Registration to apply to the whole of the Union, the Editor of "The African Architect" produces, in his first number, the Transvaal enactment, which he understands to be the working model of the South African measure. It is perhaps of less direct value in our own country, but will nevertheless be read with interest for any light it may be assumed to shed on the Registration movement that the Royal Institute and the Society of Architects have in hand.

WHEREAS it is expedient to provide for the registration of persons publicly practising or entitled to practise publicly as architects in the Transvaal, so as to distinguish qualified from unqualified persons:

And whereas it is necessary to provide a qualification for admission to the Register of Architects;

Be it enacted by the King's Most Excellent Majesty by and with the advice and consent of the Legislative Council and Legislative Assembly of the Transvaal as follows:—

Use of Title of Architect Restricted.

1. After the expiration of six months from the coming into operation of this Act no person shall describe or hold himself out as an architect or use any name, title, addition, or description, or letters indicating that he is an architect, whether by advertisement, by description in or at his place of business, or residence, by any document, or otherwise, unless he is registered as an architect in pursuance of this Act.

Penalty for Infringement.

2. Any person contravening any of the provisions of section one hereof shall be liable to a fine not exceeding one hundred pounds for each offence and in default of payment to imprisonment for a period not exceeding six months.

Association of Transvaal Architects.

3. Upon the coming into operation of this Act there shall come into existence a body corporate by the name of "The Association of Transvaal Architects" with perpetual succession and the right to use a common seal and to sue and be sued in its corporate capacity, and the said body corporate shall be capable in law of taking and holding any movable or immovable property for the benefit and purposes of the association with power to dispose thereof, but so that the association shall apply its funds and assets in promoting the objects of the association and shall not at any time pay any dividend to its members. Every person registered as an architect as hereinafter provided shall upon such registration *ipso facto* become a member of the said association.

Appointment of the Provisional Council.

4. Upon the coming into operation of this Act there shall come into existence a provisional council consisting of the following persons—namely: Walter Reid, F.R.I.B.A.; Herbert Baker, F.R.I.B.A.; G. A. H. Dickson, F.R.I.B.A.; Frank Emley, F.R.I.B.A.; Archer Hosking, A.R.I.B.A.; W. H. Stucke, A.R.I.B.A.; Harry Clayton, M.S.A.; J. F. Beardwood, M.S.A.; R. Howden, A.R.V.I.A., M.S.A.; G. H. Veale; F. G. McIntosh; W. J. de Zwaan; G. St. J. Cottrill; who shall be the first members of the association of Transvaal architects and shall forthwith cause their names to be entered upon the register thereof. The pro-

visional council shall, subject to the provisions of this Act, exercise all the powers of the association until the council hereinafter mentioned shall come into office.

Should any of the said persons die or become incapacitated, or refuse to become or remain members of the said provisional council, the Governor-in-Council may appoint other qualified persons in their place.

Proceedings of the Provisional Council.

5. Upon a day to be fixed by the President of the Transvaal Institute of Architects, but not later than one month from the coming into operation of this Act, the provisional council shall meet at Johannesburg and shall at such meeting elect a president. In the absence of the president at any meeting the members of the provisional council present shall elect one of their number to preside.

At any meeting of the provisional council five members personally present shall constitute a quorum, and a majority of the members present shall decide every question to be decided by such meeting, except admission to the register, on which a majority of the whole council shall vote, and fourteen days' notice shall be given of all meetings at which the admission of members is to be dealt with.

Subject to the provisions of this Act the provisional council are hereby empowered to regulate their meetings and the proceedings thereat and the mode of carrying on the business of the association and shall remain in office until six months after the date of the coming into operation of this Act.

The provisional council shall have power to appoint a clerk or registrar and such other officers as they may deem necessary for the purpose of the association.

Persons Entitled to be Registered by the Provisional Council.

6. The provisional council shall forthwith open a register in which any person shall be entitled to be registered as an architect in pursuance of this Act who proves to the satisfaction of the provisional council within six months next after the coming into operation of this Act that at the date of the coming into operation of this Act he was resident in British South Africa, and

(a) was a member of the Transvaal Institute of Architects or of any other institute or society; or of architects of equal standing; or

(b) was publicly and *bona fide* practising as an architect in the Transvaal; or

(c) was at such aforesaid time, or prior to the coming into operation of this Act, engaged as an assistant to an architect in the Transvaal and has had at least seven years' professional experience; or

(d) that he is possessed of qualifications and experience which may be

declared by the Governor-in-Council by proclamation to be equal to those in one or other of the foregoing instances.

Persons Entitled to be Registered by the Council.

7. Upon the expiration of six months from the date of the coming into operation of this Act no person shall be entitled to be registered in the said register as an architect unless he shall prove to the satisfaction of the majority of the whole council hereinafter mentioned that at the date of his application for registration he is resident in British South Africa and has attained the age of twenty-one years; and

(a) has passed the examination for associateship of the Royal Institute of British Architects or the examination for membership of the Society of Architects of London or the examination or examinations conducted by the council and prescribed by the by-laws of the association or some other examination which may be declared by the Governor-in-Council by proclamation to be equivalent to one or any of these examinations, and has in addition had at least four years' professional and practical experience as an assistant to an architect; or

(b) that prior to, or at the time of, the coming into operation of this Act he was registered as an associate or fellow of the Royal Institute of British Architects of London or the Transvaal Institute of Architects or of some other society or institute of architects which the Governor-in-Council may by proclamation declare to be of a standing equal to that of one of the said institutions.

Applicant Refused by Council may Apply to Supreme Court.

8. Where the council has refused to register the name of a person applying to be registered under sections six and seven, such person may apply on notice of motion to the Supreme Court for a review of the decision of the council, and the said Court may thereupon make such order as it may deem fit.

Register.

9. The provisional council or the council, as the case may be, shall, within a week after the registration of any person under this Act, transmit to the Colonial Secretary a duplicate of the said entry and the Colonial Secretary shall cause a duplicate of the aforesaid register to be kept in his office. Every change affecting the Register shall be noted therein and notified to the Colonial Secretary.

Registration Fees.

10. No person shall be placed upon the register until he has paid such registration fee, not exceeding five guineas, as shall be fixed by the provisional council or the council, as the case may be.

Resignation by Members.

11. It shall be lawful for any person whose name has been placed on the said register and whose professional conduct is not then the subject of investigation at any time to resign by writing under his hand addressed and delivered to the council and thereupon his name shall be removed from the said register and he shall cease to be registered as an architect and to be a member of the association.

Annual Subscription.

12. Every member of the association shall pay an annual subscription at such time and of such amount as shall be fixed by the by-laws framed as hereinafter provided, provided however that members who have ceased to practise shall be

entitled to remain on the register without being liable to pay such subscription but shall not be entitled to be officers of the association or to be present or vote at any of the proceedings of the association or to be reckoned in any quorum unless they shall have paid such subscription.

Recovery of Subscription.

13. All sums of money due by members to the association for registration fees or subscriptions may be recovered in the court of any resident magistrate within whose jurisdiction the debtor may reside. An affidavit by the secretary setting forth the necessary facts shall, in cases by default, be *prima facie* evidence upon which the court may grant an order or pronounce judgment by default in such suit and such judgment shall be enforceable in ordinary course of law.

Election of the Council.

14. On such day during the currency of the sixth month next after the date of the coming into operation of this Act as the provisional council shall appoint they shall convene a meeting in Johannesburg of all persons whose names appear upon the register at the date on which the notices convening such meeting are issued, such notices to be posted to the registered address of such persons at least fourteen days before the date fixed for the said meeting, and at such meeting the persons present or represented by proxy in writing shall proceed to elect in manner to be provided by the provisional council a council of twelve members who shall come into office upon the expiration of six months from the date of the coming into operation of this Act and thereupon the provisional council shall hold office until the date of the first or next council meeting as the case may be when they shall retire from office.

Offences.

15. The following acts and practices, whether of commission or omission, upon the part of any architect shall be offences under the provisions of this Act and, if found guilty by the Supreme Court of having committed or engaged in any one or more of such acts or practices, such architect shall be liable to be suspended from practice for any period that may be decided on by the said Court or to have his name removed from the register as hereinafter provided; that is to say:—

(a) allowing any person except a registered architect in partnership with himself to practise in his name as an architect;

(b) directly or indirectly sharing his professional remuneration with any person, not being a registered architect in partnership with him, or directly or indirectly accepting any share of the professional remuneration of such person or any commission or bonus thereon;

(c) signing accounts, statements, reports, specifications, plans, or other documents purporting to represent any architectural work performed by himself which work shall not have been performed under his personal supervision or direction;

(d) directly or indirectly paying a person a commission for bringing him work, giving any person monetary or other consideration as a remuneration for bringing him work, or for inducing other persons to give him work;

(e) touting or otherwise improperly obtaining or attempting to obtain work;

(f) performing any architectural work in connection with any matter which is the subject of dispute or litigation upon condition that only in the event

of the said dispute or litigation ending favourably for the party for whom the work is performed shall payment be made for such work;

(g) conducting himself unprofessionally or dishonourably in connection with any work performed by him as an architect;

(h) wilfully disobeying, refusing, or neglecting to carry out and perform any by-law or order lawfully adopted and established by the association regarding any point of professional practice;

(i) engaging in any practices or performing any acts similar to those acts and practices prohibited in the foregoing sections.

Enquiries into Conduct of Members.

16. If the conduct or behaviour of a member of the association shall appear to the provisional council or the council to require investigation, they shall before proceeding against such member in the Supreme Court as provided in the next succeeding section, hold an enquiry and, if required by such member, hear evidence on the matter. Eight days' written notice of the charges against him and of the date of such enquiry shall be given to the member concerned, who shall be entitled to appear at such enquiry to answer such charges and to produce evidence on his behalf, and his own evidence (if any) shall be admissible against him in any other proceedings, civil or criminal. If such member requires evidence to be heard the provisional council may also hear evidence against such member. Where evidence is to be heard the president or vice-president may administer the oath to witnesses and such witnesses shall be subject to the law relating to perjury.

Proceedings for Suspension and Removal of Members.

17. In the event of any member of the association being in the opinion of the provisional council or council guilty of any act or omission prohibited by this Act, or offending against any by-law or regulation framed thereunder, the provisional council or the council may call upon such member to show cause to the Supreme Court of this Colony why he should not be prohibited from practising as an architect, and why his name should not be removed from the register. All such proceedings shall be taken in the name of the association. Upon the hearing of any such matter the Court may suspend such member from practice, remove his name from the register or make such order as may seem fit, and may further make such order as to costs as may seem fit. In case of such suspension or removal, copies of the order of Court shall be lodged with the Colonial Secretary and the associations and noted in the register.

Penalties.

18. In the case any member of the association shall in consequence of an order of Court be suspended from practising as an architect in this Colony, such person shall, during such time as he is suspended, cease to be a member of the association, but shall nevertheless be liable to pay all moneys due by him up to the date of such suspension.

Persons having no Claim against the Assets of the Association.

19. No claim against the assets of the association shall exist in the case of, or be made by any person whose name has ceased to appear upon the register of the association.

Titles allowed to Members of the Association.

20. Every person whose name appears on the register shall be entitled to style himself "Registered Architect, Transvaal."

Rules and Regulations for Examinations.

21. The council shall, upon being elected to office, forthwith frame rules and regulations for regulating the examinations or equivalents thereto which shall be required of applicants for registration under section seven of this Act.

Powers of the Council.

22. The council shall have power to do each and all the following Acts:—

(a) to manage and superintend the affairs of the association;

(b) to appoint and remove any servants of the association and to determine the duty, salary, and remuneration of the same;

(c) to accept or refuse for good cause any application for registration made in pursuance of this Act;

(d) to hold examinations for applicants for registration and to grant certificates to such persons as have satisfied the examiners in such examinations;

(e) generally to exercise all the powers of the association, except such powers as are expressly reserved by this Act to the association in general meeting.

Persons in Arrear with Subscriptions not Qualified to Vote.

23. No person who is in arrear with his subscription shall be qualified to be present or vote or be reckoned in a quorum at any meeting of the provisional council or council, or of members, while he is so in arrear.

General Meetings.

24. There shall be held once in each year a general meeting of the association whereat every architect upon the register who is not disqualified under section twelve hereof shall be entitled to vote personally or by proxy in writing. The quorum for such general meeting shall be fixed by the by-laws.

Any question to be decided at such meeting shall be decided by a majority of the members present or represented thereat.

The council shall prepare as at the thirty-first of December in each year a balance-sheet of the affairs of the association and an account of all moneys received and expended by the association and submit such account duly audited to the association at such general meeting for discussion and approval. The officers of the association who shall consist of the members of the council and of a president and two vice-presidents (who shall, however, be members of the council) shall be elected annually at such meeting and the said officers shall retire annually but shall be eligible for re-election.

It shall be lawful for any member or members of the association at such meeting to move any resolution which is not inconsistent with the purposes and provisions of this Act.

Chairman's Vote.

25. The person presiding over the provisional council or council or at any general meeting shall have a deliberative as well as a casting vote.

Meeting to Pass By-laws.

26. The provisional council shall forthwith prepare draft by-laws for the association for the purposes enumerated in the next succeeding section and shall convene a special general meeting of the association in Johannesburg to be held not later than six months from the date of the coming into operation of this Act

for the purpose of considering and, if approved, of adopting the said by-laws. The notice convening such meeting shall be sent to the registered address of each member of the association not later than fourteen days before the day appointed for such meeting and shall be accompanied by a copy of the said by-laws.

A majority of the members personally present or represented by proxy in writing at such meeting shall be sufficient to determine all matters to be decided thereat and the non-receipt of the said notice or copy of the proposed by-laws by any member or members shall not invalidate the proceedings at the said meeting, provided that one-third of the number of members then on the register shall be present personally or be represented by proxy in writing.

Purposes for which By-laws may be Made.

27. The council may from time to time, subject to the approval of the association assembled in a special general meeting called for the purpose, make by-laws for any of the following purposes, provided that such by-laws be not inconsistent with the provisions of this Act, and may alter, amend, or repeal such by-laws including the by-laws framed under the last preceding section, that is to say:—

(a) for fixing the amount of the annual subscription payable by members and the time of payment of the same;

(b) for defining what shall be considered unprofessional or dishonourable conduct on the part of an architect;

(c) for regulating the time, mode, and place of summoning and holding ordinary and special general meetings and the quorum to be present thereat and the mode of voting and the conduct of proceedings at any such meetings and the regulations for the adjournment thereof;

(d) for regulating the meetings of the council and the quorum to be present thereat;

(e) for regulating the mode of nomination of members for election to the

council and the mode of filling casual vacancies thereon;

(f) for regulating the times and places for holding examinations of applicants for registration and the subjects and the manner of conducting or holding any such examinations, and for fixing a reasonable fee to be paid by applicants and the conditions on which the examiners shall hold office and their remuneration;

(g) for regulating the mode of election of the officers of the association;

(h) for fixing a tariff prescribing the remuneration which architects shall be entitled to charge for their services;

(i) for determining the qualification and disqualification of councillors.

(j) and generally such by-laws as from time to time seem to the association requisite for giving effect to the provisions of this Act and for the furtherance of the objects of the association.

Alteration of By-laws.

28. No alteration in the by-laws as adopted at the special general meeting referred to in section twenty-six shall be made save by a majority of two-thirds of the members personally present or represented by proxy in writing at the special general meeting convened for the purpose of sanctioning such alteration. Notice of such meeting, and of the alteration or alterations to be proposed thereat, shall be sent by post to the registered address of each member of the association at least fourteen days before the date fixed for the meeting, but the non-receipt of such notice by any member or members shall not invalidate the proceedings thereat provided that one-third of the members then on the register shall be personally present or be represented by proxy in writing.

By-laws—when to take Effect.

29. No by-law framed and adopted under sections twenty-six and twenty-seven of this Act and no alteration, amendment, or repeal of any such by-law shall have any force and effect until the same shall have been approved of by the

Governor-in-Council and published in the "Gazette," whereupon they shall have the force of law and shall be binding upon all members of the association in so far as the same are not in conflict with the provisions of this Act.

Repeal of By-laws by Governor-in-Council.

30. The Governor-in-Council shall at all times have the power to repeal the existing by-laws of the association and may from time to time alter, amend, and add to such by-laws, provided that such alteration, amendment, and addition be not in conflict with the provisions of this Act.

Costs of Promoting this Act.

31. The Council may allocate such sum or sums of money as shall be proved to their satisfaction to have been expended in promoting this Act, and which sum or sums are, in the opinion of the council, reasonable, and may order the same to be paid through their treasurer to the body or bodies, person or persons, who may establish the claim or claims within twelve months of the coming into operation of this Act.

Title and Date of Operation of Act.

32. This Act may be cited for all purposes as the Architects Private Act, 1909, and shall come into operation and have the force of law on the publication thereof in the "Gazette."

DETAILS, OLD & NEW, XXXVIII.

Early Renaissance Altar Rails from Lancashire.

Altar rails were not introduced into the Western church until after the Reformation, consequently there are no real Gothic examples. It is to the "revivalists" that we owe those dreadful cusped and foiled and fretted perversities which are to be found in so many old churches. It does not cause any feeling of incongruity to see Renaissance fittings in old churches—many of the fittings do indeed belong to this period—they seem to be part of a continuous growth, of the opening flower, of developing life. The altar-rail was at first a barrier to keep dogs out of the sanctuary, and was made much higher than is the wont to-day. Its uses to-day are slightly different, and it may be useful to give some dimensions which, to some extent, govern its design. It should be, then, from 1 ft. to 10 in. to 2 ft. high, and set back from the step some thirteen or fourteen inches. The space behind it and the next step must be wide enough to allow the two priests who administer the sacrament to pass one another—to wit, about four feet. This early Renaissance example from Lancashire has a gate. They are made sometimes without one, but it usually adds to the beauty of the design if the rail can be continuous. There is something exceedingly rude about the rail from Bolton-by-Bowland Church, but it is pleasing, strong, and well made. Our only feeling is one of regret that the village carpenter who took these balusters out of the heart of the oak, and turned them so irregularly, and, finally, when he had mounted his curious ball-finials, took his chisel to tell to future generations that it was made in 1704, did not take thought of his own name and carve it over against the date. How much better this for a monument than some crumbling undistinguished stone rotting in a grave-yard!

J. M. W. H.

ALTAR RAILS, BOLTON-BY-BOWLAND CHURCH, LANC.

ALTAR RAIL *from Bolton-by-Bowland Church.*

THE INFLUENCE OF COMPETITION UPON DESIGN.

To describe properly the effect of competition upon architecture would require an analytical comparison of the works of representative architects, won in competition, with other of their works executed after direct selection, and taking all the attendant conditions into account.

Much has been said upon the ethics of the competition, but very little upon the actual influence of competition upon architecture; that is a very broad subject requiring separate and special consideration.

Upon receiving a paper to enter a competition, and upon receipt of the programme and requirements, one realises that he is taking up a new and strange problem, and is dealing with an unknown owner, or committee; the personnel of the jury may or may not be known to him.

In either case (said Mr. J. Milton Dyer, Fellow of the American Institute of Architects, in the course of a paper read at the forty-fifth annual convention of that Institute, at Washington), the economical idea of the plan may often be worked out independently—that is, the disposition of space and relation of departments the one with the other, circulation, etc., may be determined irrespective of any supposed idiosyncrasy on the part of the jury; but even in the case of the plan this independence is only too often influenced by a vague mistrust as to the personal likes or dislikes of the jury, concerning some particular arrangement, thus preventing an individual and heartfelt expression of the solution.

After the plan has been developed to an advanced stage, one may surround it with four walls punctured with holes, or attempt to give these walls architectural expression, and a character which denotes the intended uses of the building. Here, again, one's thoughts turn to the approval of the owner and his expert advisers, rather than to a courageous, independent, impulsive study of the problem. You are afraid to be impulsive, to play with the motives, to do the thing you yourself feel; you may not win.

While it is true that the most important element which is lacking in a competition, and which must therefore affect the final result, is the inability to get in touch with one's client, and thus develop a solution; nevertheless the viewpoint of the expert adviser and jury itself, affecting design, is greatly responsible for the prevailing desire to sell one's soul to win; and it is possible that we should have a code for the Conduct of Jurors, as well as for the Conduct of Competitions and Competitors. Must we, in competitions, be eternally condemned to the use of an order? Is there no value in wall space?

The late John M. Carrère has said that one argument advanced in favour of competition has been the desire to discover new talent, and added, "If a man has talent, his day will come, and it should not come until he is prepared to make use of it."

"A man who has genius to express original ideas on paper is nevertheless not to be entrusted with the execution of the work until he has acquired the requisite experience, for when it comes to the serious work of actual building he requires not only the experience of the practical side of things, but the practical artistic experience; the experience that knows that a thing that looks well on paper represents a thing that is going

to look well in execution; and *that* refers to every detail of the work, the very texture of the material. It requires experience which cannot be acquired by any man, no matter what his genius may be, without practice."

The author believes that the safe, dignified, substantial way in which to obtain recognition in the profession is to gain your clientele through the excellence of your executed work, the importance and value of which will grow as rapidly as it deserves; nevertheless, it has been his experience that the presence of a serious competition in the office does develop men, from the head to the office boy, improving draughtsmanship, knowledge of the principles of design, and the faculty of quickly expressing one's thoughts on paper. An *esprit de corps* is created in the office, for here is a real competition, something more than a school problem, and naturally all take a keener interest in the result. Great good is accomplished in the ateliers of our larger cities and the competitions instituted by the Beaux-Arts Society, and by several magazines, but the efforts of all in collaboration, working in an office upon a serious competition, develop not only draughtsmanship, but a real conception of architecture in its higher meaning, such as many months of routine work may not accomplish.

A great number of competitions, even in some of our best-known offices, have been won by clever young designers, developed under these conditions of training.

While this should not necessarily warrant these men being selected as architects, it nevertheless demonstrates that the system of conducting competitions does not stand for training in design. It is equally true that a number of these young men have, through the medium of competitions, developed into some of the prominent architects of the country, and have shown, by their subsequent work, that they were prepared to make use of their talents.

In America, the Tarsney Act, approved February 20th, 1893, authorising the Secretary of the Treasury to obtain plans and specifications for public buildings, paved the way for a better architecture in the federal buildings, and has in turn, since its adoption, reacted upon the work of this Department of the Secretary of the Treasury, until, as Mr. Glenn Brown, in his review of 1906, states: "Under the Tarsney Act it must be conceded that the work is immeasurably superior to any building done by the Government from 1860 to 1896, and it, together with the merit system which now rules in the office, has been a very material factor in uplifting the character of work done by the corps in the supervising architect's office during the past six years."

Since 1897, under the direction and with the advice and assistance of the officers of the American Institute, programmes have been drawn by the supervising architect for scores of important Government buildings throughout the country, and the result has been public buildings of an excellence of design and execution heretofore unknown in the United States.

These competitions, however, have affected design to an enormous extent. The type of architecture in American Government buildings, as well as other municipal and semi-public buildings, has for the most part become circumscribed. Before the drawings are sent in, it is almost [possible to foretell, within small limitations, the general character of the

design of the contestants. It is always the base storey of a superimposed order, enclosing two or more storeys, with perhaps an attic, or the order will extend from the ground through all the storeys. In any case it is almost sure to be an order, and, as before stated, the value of plain wall space in design seems to be overlooked.

This use of the order as the main feature of a building, with several storeys enclosed in its height, is seldom successful, and probably never when more than two storeys are included.

Why does competition insist upon a Government type requiring architects to crowd these many storeys within the order, thus making corridors of the rooms within, by reason of the usual depths, or rooms too large for an economical arrangement of space, when the logical expression of an economical plan demands that the window openings be made subservient to this plan? In other words, while the character of architecture should proclaim the dignity and purpose of the building, why should the arrangement and lighting of the interior be sacrificed to the everlasting order?

Does the fact of the order in competitive design spring from the belief that this form of architecture is really the established form for public buildings in the United States, or is it to be laid to the door of the system of conducting competitions?

If the latter be true, the author again affirms that the cause lies in that inborn desire to win, and the competitor, in order to do so, gives the jury that official type he believes the jury wants, to the absolute abasement of personal expression and the results of practically all competition judgments prove that he is correct. The jury does demand the recognised official type.

It therefore appears to the author that, in competitions, the jury and expert advisers exert fully as much influence upon design as the competitor himself.

The official type of public buildings, whether for the Government or a municipality, is the offspring of the competition as at present conducted, and, in turn, influences and very often determines the type for many buildings forming part of a grouping plan, such as is being developed in many of the larger cities, thus condemning the whole group to a type which most surely will not be the last word in the architectural expression of public buildings.

Much that has been herein stated may also be said concerning competitions for buildings of a commercial character.

With a possible exception, as in the case of those problems of great monuments which are purely artistic in their character, and which may require the collaboration of the sculptor or decorator, taking into consideration the present status of the competition, the author believes the best method of securing an artistic as well as a practical result is by the direct selection of an architect. But the fact that competitions have been conducted in Europe, and especially in France, for many years with undoubted success, exerting a marked and beneficial influence upon architecture; also the willingness on the part of most of our ablest architects to enter competitions with, as a result, hundreds of successful monuments attesting their skill; and the fact that perhaps more time of the Institute Conventions is devoted to the consideration of the problems pertaining to the competitions than to any other subject—indicate that, while the perfect

Code for the Conduct of Competitions, Competitors, Jurors, and Clients has not yet been developed, nevertheless we may, through a progressive process of education, evolve a system which will eventually enable competition to exert a beneficial effect upon design in architecture.

MANCHESTER SOCIETY OF ARCHITECTS.

Sir Charles Nicholson on Construction and Design.

On Wednesday, January 17th, Sir Charles A. Nicholson, Bart., read before the Manchester Society of Architects a paper on "Construction and Design." The president, Mr. Edgar Wood, occupied the chair, and there was a very large attendance of members.

Sir Charles Nicholson said he would confine his remarks that night to Gothic work. One point became obvious—that as cathedrals were built in a leisurely way, each section, and even each bay, had to be structurally independent and self-supporting. Norman buildings lent themselves to this gradual method, but in Gothic structures strong temporary abutments had to be provided. The weakness of Norman buildings was due to the bad material rather than to thrusts; the collapses of Winchester, Chichester, and Ely towers were due to this cause. The weakness of Gothic structures was that they were maintained in a precarious state of equilibrium which approached instability.

Sir Charles then analysed the development of Gothic construction, first as regards the relation of buttresses to the vaults they supported, then as to the development of the vaults themselves, and finally, the evolution of the apse plan, paying special attention to the parallel process of evolution in England and France. Many points of interest in the construction of Wells Cathedral were instanced, and a section of the tower which was thrown on the screen was specially interesting, showing how the upper stages had been built as light as possible, and how the piers below had been strengthened by the well-known strainer arches and the solid rood screen, and how the tower was latterly stiffened by the filling up of the long lancet windows of the lantern. The ingenious way of augmenting the thrust of the eastern flying buttresses was illustrated; the lower portion of the buttresses, which are received by the slender marble shafts in the Lady Chapel, are built with courses oversailing towards the west. After a survey of the period of fan vaulting, the lecturer dealt with the application to modern construction of the principles which we could discern in the old work. How modern materials should be treated was a question still awaiting solution. Slides representing reinforced concrete buildings, where the concrete was honestly revealed and the monolithic nature of the structure expressed, were shown. In concluding, the lecturer said that the present generation of architects was capable of evolving artistic solutions of each fresh constructive problem that arose, but the large supply of knowledge to be gained from the stupendous works of the old masters of our art cannot be neglected.

Mr. Maule on Architectural Education.

On Wednesday, January 24th, Mr. I. P. G. Maule read a paper on "Architectural Education." The broad basis of education, Mr. Maule said, was not the

superperfect equipment of the giant few, but the sound, sane, and sober training of the many. Specialisation is increasing, but it should be based on a broad and solid foundation of general knowledge. The more everything tends toward specialisation, the longer must be our apprenticeship. He felt that there had not always been sufficient regard paid to the psychology of education, the induction by training of certain habits and qualities, apart from the particular objective.

When a student is brought from practical training to the forced draught of the school, he gets general and special knowledge in an artificial and tabloid form, at the expense of training in initiative and self-reliance, and in observation and deduction. This system is then doomed to failure unless the student is brought into contact with the facts of actual existence which he will afterwards meet. There is a general feeling among educationists that our systems fail in this regard.

In addition to neglect of this aspect, there is a tendency to confuse the issue of general and specialised education. The highly specialised forms of architecture have been regarded as the goal of all. He referred to the erroneous impression that monumental design should form part of the first four years' course. Is there any recognised training in the arts, sciences, or professions in which the highest ultimate problems were given at an elementary stage? It does not follow, however, that because monumental problems are relegated to an advanced stage, the qualities which underlie the production of great architecture would be neglected. They would be insisted upon from the commencement, in problems, however simple and small in scale, with a view to the ultimate larger conception of monumental architecture.

The chaotic state of opinion is shown by the report of the Board of Architectural Education recently issued, which, while containing much that is excellent, suggests an amount of ground to be covered in four years which is simply abnormal; and the matter is further complicated by the present state of architectural politics. He felt, however, that some definite idea as to the real objective might be found.

He thought the following main principles should be recognised:—

(1) The compulsory insistence on a general training of not less than four years, two of which should be passed in an architectural school. The standard might rank with the present Intermediate papers.

(2) The formation of machinery for more advanced and specialised study, the first grade of which should rank with the present final papers. The remaining advanced courses would be of the nature of specialisation.

(3) Greater time for study by all who wish to do more than acquire a minimum standard.

The whole question hinges upon the interpretation of the functions of the architect, and the recognition of the fact that architecture is structural and decorated, and *not* a decorated art constructed—a living, pulsating structure; no scene-painting in stone, with the engineer as stage carpenter. The essential qualities of the general education should be—(1) Scientific study of materials and construction in their elementary form. (2) Analytical study of past building methods and architectural expression, and the deduction from this of the broad principles

of design. (3) The application of the above—the production of design from knowledge and study of principles. The study of the humanities of art should form part of the training from the very first. This general training, he was sure, from a varied experience, could not be mastered by the average student in less than four years.

LEICESTER SOCIETY OF ARCHITECTS.

Mr. H. E. Trayleur on the Architecture of Stamford.

A meeting of this society was held in the society's rooms, in St. Martins East, on Friday last, there being a good attendance. The President (Mr. W. M. Cowdell, F.R.I.B.A.) was in the chair. An interesting lecture on "The Architecture of Stamford" was given by Mr. H. F. Trayleur, A.R.I.B.A., who, after giving a brief introductory history of the town, dealt with eleventh-century architecture, drawing attention to important points of development. He then went on to speak of characteristic thirteenth, fourteenth, and fifteenth-century work, and also examples of Tudor, Queen Anne, and Georgian houses, almshouses, and other characteristic local work, including some Sheraton shop fronts. The lecture was illustrated by lantern slides, including a number of views of Burleigh House.—A vote of thanks was accorded the lecturer on the motion of Mr. S. Perkins Pick, seconded by Mr. B. J. Fletcher, headmaster of the School of Art, and supported by Ald. A. E. Sawday, Mr. Herbert, and the president.—In responding, Mr. Trayleur expressed his willingness to give to the society a number of the architectural drawings of the late Mr. F. W. Ordish, with whom his father was formerly in partnership. The suggestion was heartily applauded.

THE ARCHITECTURAL ASSOCIATION OF IRELAND.

An ordinary meeting of the above body was held last week at the rooms, South Frederick Lane. The President, Mr. Page L. Dickinson, occupied the chair, and there was a large attendance of members.

The President announced that Mr. A. W. Reid had resigned the vice-presidency in order to take up the post of secretary, which was rendered vacant by the resignation of Mr. H. T. O'Rourke, and that the committee had nominated Mr. G. L. O'Connor as vice-president in his stead, and his name will go forward for election at the next general meeting.

Mr. R. M. Butler, F.R.I.B.A., then delivered a lecture on "Early Romanesque Architecture in Ireland," illustrated by numerous lantern slides. At its conclusion, Mr. Anthony Scott, in proposing a vote of thanks to the lecturer, referred to various details of the buildings described by Mr. Butler. Mr. Lynch seconded the vote of thanks, and said he was glad such emphasis was laid on the value of Petrie's work, as in his opinion it was the most reliable treatise on the subject to be had.

Mr. Butler, replying said that in his opinion it was a lamentable fact that the memory of a man like Petrie, who had done so much for archaeological research in Ireland, was not perpetuated in some way, and it was to be regretted that his remains should lie in Mount Jerome Cemetery covered by a plain slab of stone about two feet square.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

Mr. William Davidson on East Anglian Rural Churches and their Decoration.

At the general meeting of this Society held on January 25th, Mr. Wm. Davidson delivered a lecture on "East Anglian Rural Churches and their Decorations." The chair was occupied by Mr. A. E. Kirk, A.R.I.B.A., vice-president.

In opening the lecture, Mr. Davidson said that in no other part of England, during the Middle Ages, had there been a greater activity in ecclesiastical architecture and decorative and applied art than in East Anglia. Many fine examples of all periods of architecture, from the pre-Conquest work, as at Great Dunham, to the great Perpendicular rural churches of the fifteenth century, such as Walpole St. Peter, Causton, Sall, etc., were shown and described. The influence of material on the design was illustrated by the great prevalence of flint work (no other building stone being readily available), built either in the form of concrete walling, or used as a mosaic facing in various colours. The frequent use of round towers was also held to be due to the same cause—lack of stone for corners and dressings.

Of Norman work, the central tower at South Topham; the arcades at Castle Acre, Walsoken, Binham, Wymondham, Hales, and Hadleigh; and the doorways at Thwaite, Aldeby, South Burlingham, and Easton, were described as fine examples. The beautiful parish church at West Walton, with its magnificent lych-gate and bell campanile, and the west front at Binham, were stated to be as fine Early English detail as any in the country. The stone carving of the nave pier caps at West Walton marked the high-water mark of such work in England.

The Pilgrims' Chapel at Houghton-le-Dale was given as an exquisite example of Decorated work. In discussing the transition from Decorated to Perpendicular, instances were quoted which in the lecturer's opinion proved conclusively that these two styles were very much mixed up, as it was perfectly evident that much of the Decorated work was executed long after the birth of Perpendicular, showing that even in the best and most traditional of the so-called "good old days" men were not above copying a "good old style." This mixture of the ridged and flowing lines gave the Perpendicular work in Norfolk a freedom of charm not to be found in work of the same period in other parts of the country.

In speaking of the great churches of the fourteenth and fifteenth centuries, the main dimensions of a few were given, and the evolution in plan was described. In the East Anglian church, the chancel roof was usually lower than the nave (Long Melford and Southwold were quoted as notable exceptions), from which it was generally separated by a chancel arch and a rood screen, and in some cases a window existed in the east gable of the nave, over the chancel arch. The loftiness of many of these churches, with their high clerestory windows, was shown by examples at Sall, Cawston, Upton, and Potter Heigham. Views were shown of the great towers at Sall, Cawston, Blofield, Tunstead, Wymondham, Lavenham, etc., which, in some cases, Mr. Davidson considered, from their unfinished appearance, must have originally had a wood or lead lantern such as we find at East Harling, Swaffham, Aylsham, etc. The walls of some of these towers were 7 ft. thick at the ground level.

Many north and south porches with decorative flint work and carving existed, among others, Worstead, Lavenham, and Kersey being mentioned and shown as good examples. The great wealth of fine font covers was illustrated by many notable examples. Walsingham, Upton, Hadleigh, and Palgrave being specially mentioned; also the font covers of various types, particularly those of Trunch and Sall, which showed traces of the original colours.

Slides were shown of single and double hammer-beam roofs, which, along with the rood screens and fonts, were the glory of their eastern counties. Of the single type Ludham, Potter Heigham, North Burlingham, Trunch, and Southwold were stated to be among the most beautiful in composition, line, and design. The magnificent double hammer-beam roofs at Knapton and Cawston were illustrated by many detail slides, giving a poetic impression of their beauty under various conditions of lighting. The evolution in design from the stone roof was traced, and the various schemes of roof painting were given in detail.

A short account was then given of the famous painted rood screens of Norfolk and Suffolk, and many beautiful examples of figure painting were shown, with details of mouldings and floral painted ornaments. A description of the main colour schemes was given. Several schools of figure painters were shown to have existed, and the lecturer had no doubt whatever as to nearly all the work being that of English artists, though foreign influences were clearly evident, notably Florentine, Flemish, and German. The archaic influence of the Byzantine was said to have survived to a later date in the English Gothic than in the Italian, probably about 100 years.

In speaking of screen and wall paintings, Mr. Davidson expressed the opinion that these do not seem to have been properly studied, otherwise the great beauty of many of these fragments would be pointed out more to students of decorative art. Mr. E. W. Tristram, of London, has, however, taken up the study of English mediæval wall painting seriously, and it was to be hoped that his fine collection of drawings and research would one day be published. On the Continent such work is done at the expense of the State. Many rooms at the National Gallery were devoted to Italian and other foreign schools, but we may hunt in vain for a solitary example of our own great mediæval school of decorative art. No one wished to see these paintings taken out of their right place in the churches, but there are many fine examples in the hands of private persons, a few of which could surely be acquired for the nation.

In concluding his paper, Mr. Davidson showed and described the work of various crafts, such as glass, iron, brass, and leather work, the fine quality of which showed how all the arts arose and developed with that of architecture. The mediæval church in East Anglia, at the height of its splendour, possessed a great architectural and decorative unity, and must have simply glowed with colour; tiled floors, frescoed walls, painted screens, painted roof, and stained glass, all blending harmoniously together. In such work we have a great heritage and inspiration, but under existing conditions it is difficult for even the best of men to do their best and to emulate such glorious work. The lecture was illustrated by numerous detail drawings, water-colours, and lantern slides.

ARCHITECTURAL ASSOCIATION.

Visit to the Regent Street Polytechnic.

The second spring visit of the Architectural Association took place on Saturday, January 27th, when many members took the opportunity to visit the new buildings of the Regent Street Polytechnic designed by Mr. F. T. Verity, F.R.I.B.A. and Mr. George A. Mitchell, A.R.I.B.A.

The building consists of a new block with a frontage to Regent Street, and reconstructed gymnasium block at the rear. The whole of the structure is steel framed, with reinforced-concrete floor slabs averaging 21 ft. by 7 ft. 6 in. All the steel work is riveted, as extreme rigidity is required in many of the laboratories and rooms.

The foundations of the front block consist of a reinforced concrete grillage with steel grillages under the stanchions. The vaults under the pavement and retaining wall, and also the staircase, are of ferro-concrete on the Hennebique system. The height of the building from the top of the concrete grillage to the roof is 130 ft.

The facade is in Portland stone, and is part of a larger scheme which is to be completed later. It was erected to the designs of Mr. F. T. Verity, F.R.I.B.A. A drawing showing this scheme, together with a $\frac{1}{2}$ in. detail, were exhibited.

The new block, facing Regent Street, has nine storeys, including two basements, the ground and six other floors.

The ground floor has a large entrance hall, 60 ft. square, and is lined with various coloured marbles. The main staircase is placed centrally, and extends to the top floor; and each floor is planned with a central corridor and class-room opening from both its sides.

The walls to the first floor on the staircase are lined with marble. On each side there is an electric passenger lift for all floors of the staircase.

A large concert hall, seating 700 persons, and the Fyvie Hall, seating 300 persons, and various administrative offices complete the ground floor.

The Fyvie Hall is panelled in Austrian oak, and has an ornamental plaster ceiling, and a row of stained-glass windows on one side.

The first floor includes a games room with various club rooms opening out of it, and the remainder of this floor is occupied by the administrative staff and laboratories.

The second and third floors are divided into class and lecture rooms, which are occupied by the various departments of the day and evening schools.

The fourth floor is used by the School of Architecture and the School of Photography, and generally conforms to the planning of the two floors below.

The fifth and sixth floors are occupied by the School of Art, and the sixth floor, being the topmost, is lit from the roof and with north light only.

This floor is used for the life and modelling rooms.

The roof is finished with a float cement surface, and there is access to all parts of it. The portion facing Regent Street is covered with green Westmorland slates.

In the basements, workshops are provided for practical instruction in electrical, building trades, and mechanical engineering work.

The hot-water installation is also here. The building is heated by the low-pressure hot-water system with a forced circulation and three boilers are provided. Two are sufficient to do the work, and the third

REGENT STREET POLYTECHNIC, LONDON: DETAIL OF FACADE. FRANK T. VERITY, F.R.I.B.A., ARCHITECT.

only for cases of emergency. The boilers are also used for heating the swimming bath, which is used during the summer months only.

The gymnasium block, which has been reconstructed, consists of a basement and three floors. The original floor of the gymnasium has been sunk to basement level, and the old floor level is now gallery level. The gymnasium locker rooms and the swimming bath are also in the basement. The swimming bath, which is part of the old building, and has not been altered, is 80 ft. by 30 ft.,

and is used only in the summer months. A new system of supplying and purifying the water is to be installed, the contractors being Messrs. Royles and Co.

The walls of the gymnasium were found to be too weak to support the new gallery, and they have been strengthened with stanchions, from which the gallery is cantilevered.

The floors above are used as classrooms, and there is access to them from the half-landings of the main staircase.

The floors of the classrooms throughout are of concrete, and are floated to a

smooth surface and covered with linoleum. The corridors are finished with a paving of granolithic.

The concert hall, gymnasium, and lower parts of the building, are ventilated by a combination of the plenum and the extraction systems, the air being screened, washed, and ozonised before being forced through the ducts.

Two suction plants are installed for cleaning by the vacuum process. The building has been constructed at the cost of £90,000, and the general contractors were Messrs. Holloway Bros.

LONDON: AN ARCHITECTURAL SYLLABUS.

LECTURE BY PROFESSOR BERESFORD PITE.

On Wednesday last, at the Carpenters' Hall, London Wall, Professor Beresford Pite delivered a lecture on "London: An Architectural Syllabus," illustrated with a large number of lantern pictures.

Professor Pite said that his lecture had the idea underlying it that London had in itself the material for forming a useful architectural syllabus of opinion, of doctrine, and of criticism. For this it was not necessary to travel abroad.

Within recent years there had been considerable growth in public interest in architectural matters, and the most recent event that had happened in the architectural world was an event of very great importance—he referred to the publication by the Government of a new plan for an improvement of the access of the great arterial roads to and around London; for the link between the traffic plan and the architectural object was a very close one. There was a real architectural syllabus in London provided by law; that was to say that there were limits set which entirely governed their proceedings and designs, and which, in a sort of subconscious way, issued in architectural results. The London Building Act, 1895, dealt among other things with the formation of streets with open spaces around, and the height of buildings, and there was an architectural aspect in each one of those headings. It dealt with the structure and thickness of walls; it provided rules for recesses and openings; rules as to height; with roofs and their angles; with dormer windows, chimneys, staircases, projections, etc. They could not discuss or create an architectural design without dealing with every one of those items, and every one of them laid down distinctive rules.

That was the Act which every architect and every designer came up against the very moment he attempted to design a building for London. There was therefore an effective syllabus in existence with regard to all those particulars. It would at once be seen that architects and builders in London were confined within very narrow limits. When the architect had instructions, when he was inspired with a brilliant idea, he had battles with the difficulties of the cost and the plan. After he had surmounted them one after the other, he had to bring everything to the desk of that benevolent tyrant the district surveyor, who proceeded to lay down or to apply the law. All those visions of what might be done to impart freshness and charm to city life were subject to the necessity of applying to the London County Council for amending certain of its conditions.

There were plenty of other doctrines on which they might build a syllabus. There was a syllabus of taste which reflected current culture; they might derive a syllabus from social conditions which were reflected in our buildings, besides the evidence of the constructional syllabus to which he had referred. The social syllabus would begin with houses when the merchant lodged over his counting house in the City, some of which houses still remained with us. At that time many went to the artistic district of Bloomsbury Square and others had their ancestral mansions in Lincoln's Inn.

Another generation passed and the social centre shifted to the stucco mansions of Belgravia, and the artistic

brotherhood flitted to the heights of Hampstead. Yet another generation came, and in our time modern London might be described as a motor world, and London itself as a garage or restaurant. The whole of London was a museum out of which it was possible to construct a social syllabus as well as a constructional syllabus. The finest architecture of London was produced before Greece was heard of. They could pursue the universal syllabus and say that following upon Greece, which created the finest architecture of the world, they had the imperial magnificence of Rome, which built the Forum and aqueducts, and the roads of the world. It was interesting and remarkable to note that probably in England alone the preceding civilization of Rome had left not a trace upon our indigenous architecture. Greece did not come first with us, and Rome did not come second—they were come and gone before we commenced. The English architectural syllabus really began with the Gothic architecture which had given us a magnificent collection of mediæval buildings in London. After the Gothic, England began to wake up to its position in the general syllabus. Gothic was the first point at which we came into contact with the first architecture of civilization; that was to say, the architecture of the Middle Ages, which had its existence in England for the first time. After the Gothic they came to the period of the Renaissance, and England had her place in the universal syllabus, though somewhat late in the day. The greater buildings of the Renaissance in Italy were built and completed while we were still building Henry VII.'s chapel at Westminster. It was not until the modern era that England could be said to be leader. Such a syllabus as he had described was only apparently historical; it was not really so, and it was only superficial in the sense of its being concerned with æsthetic ideas, not with the real architectural interest. He could find a Greek building in London when he looked at the British Museum; he could find Roman buildings and Italian buildings, but they were imitations, not revivals.

He was going to suggest to them that evening an architectural syllabus which was a constructional syllabus as well as historical. To give them a rough notion of what he meant by an historical syllabus he would just run through on the one hand the constructional development of London, and they would see that they could put on the other hand the historical development of London, and between the constructional syllabus and the historical he hoped they would get the guidance which they needed. Constructionally the first element in the syllabus was the London of wattle and mud. The first London was constructed of those two materials. London at that time was something more than a fishing station, it was a commercial station on the shores of the river.

The second stage in the constructional syllabus was rubble London. Rubble, he suggested, could be connoted with rubbish—he did not mean a London of rubbish, but he meant a London the walls of which were built of rubble stone—undressed, scrappy stone, with a large amount of crude mortar. Rubble London was Gothic London; mediæval London; it was the London of the Tower and of the cathedrals. Rubble London was followed by wooden-framed London; and wooden-framed London lasted all through the Middle Ages well into the

time of Queen Elizabeth. Henry VII had a big wooden palace at Nonsuch. Wooden-framed London was dealt with in a most drastic way by the Great Fire—it was wiped out. The fire of 1666 therefore put an end to the third item in the syllabus and brought them face to face with the fourth, which was brick London, and that London covered the period of Charles II. and Queen Anne. Brick London was associated, as rubble London was, with stone dressing and stone ornaments, but the treatment of stonework in connection with the brick work was different from the treatment of stonework when it was used in connection with the rubble masonry; it became finer and more interesting—in fact, it became masonry of a high order, so that they were shortly face to face with the next item in the syllabus—Portland-stone London—when it was felt that all architectural design lay in a finely finished smooth-faced stone wall. To this period of course belonged St. Paul's Cathedral, followed at a later date by Somers House. From Portland-stone London the next item in the syllabus was stucco London. He admitted that stucco London was very much more dignified and in many ways more interesting, but it was stucco London for all that. Many examples of stucco London were to be found in the City, such as in King William Street and in many places in the West End—it was the architecture of Regent Street; it was the material of Carlton House Terrace. They were now getting near their own time, although they felt a lingering sympathy with the stucco movement still, and they came to the last item in the syllabus—the item with which he commenced: the Building Act London, or modern London.

In that connection he must not forget to mention as an important element in the Building Act London what he ought to call post-cholera London—sanitary London. He did not think he would be far wrong in believing that the greatest interest of modern London to future generations would lie in its large drainage system and in the remarkably beautiful planning that was now done in lasting permanent materials.

Professor Pite then threw on the screen a number of pictures to illustrate the various styles of architecture touched upon in his lecture.

In conclusion, he said that we were in an interesting and enlarging period and we might be on the eve of big changes. He hoped that our accidental aspirations might not come to an end, but that there might still remain among them those characteristics of the English school which had made the nineteenth century so important in its freedom and in its original dealing with building. London had nothing at the present moment to fear from a comparison with Continental countries, though he was bound to admit that Berlin was making very rapid strides after them.

Architecture at London University

The offer which has been previously announced, made anonymously through the Chancellor of London University, to provide at University College, a cost of £30,000, accommodation for teaching of architecture, sculpture, and æsthetics, has been "gratefully accepted" by the Senate of London University, and Professor F. M. Simpson, F.R.I.B.A., has been appointed architect for the buildings.

NEWS ITEMS.

Change of Address.

Mr. T. Millwood Wilson, architect, has removed his offices from 34, New Bridge Street, E.C., to 4, Staple Inn, Holborn W.C.

Fall of a Ceiling: Damages Awarded.

At Marylebone County Court, last week, a man was awarded £4 damages for injuries sustained from a portion of a ceiling falling upon his head in a room of which he was a weekly tenant.

London Road Schemes.

It is authoritatively announced that a statement recently made to the effect that the Road Board have under consideration proposals for the expenditure of 30 millions on new roads of approach to London is entirely without foundation.

Hospital Heating.

The Dutton Isolation Hospital, near Runcorn, is being supplied with Shorland's warm-air ventilating patent Manchester stoves with descending smoke flues and grates, by Messrs E. H. Shorland and Brother, Ltd., of Failsworth, Manchester.

Memorial to Principal Lang, Aberdeen.

A memorial to Principal Marshall Lang that was unveiled last week in King's College Chapel, Aberdeen, consists of a large bronze tablet, with a bust of the late Principal in low relief, and an inscription stating that it has been erected by his children. The sculptor is Mr. John Tweed.

A Too Accessible Flat Roof.

A curious disadvantage of accessible flat roofs was demonstrated last Wednesday, when a young ox that was one of a herd being driven to the Corporation slaughterhouses at Islington broke away, and, running into one of the entrances of a four-storey tenement, climbed the stone staircase and got on to the flat roof. Here, after it had demolished a chimney-tack and some other brickwork, it was eventually shot.

New Professor at the Royal Academy.

Mr. A. P. Laurie, M.A., D.Sc., some-time Fellow of King's College, Cambridge, Principal of the Heriot-Watt College, Edinburgh, has been elected to the Professorship of Chemistry in the Royal Academy vacant by the resignation of Sir Arthur Church, K.C.V.O., F.R.S. Dr. Laurie, who is the eldest son of Professor S. Laurie, was born in 1861, and had a distinguished career at Edinburgh and Cambridge Universities. Among the scientific works he has published are "Processes, Pigments, and Vehicles—Manual for Art Students," 1895; "Greek and Roman Methods of Painting," 1910; and "Materials Used in the Painter's Craft from the Earliest Times to the End of the 17th Century," 1911. He has been examiner in Oils and Colours at the City and Guilds Institute.

National Insurance Act, 1911: Advisory Council.

We are informed that the National Insurance Advisory Council, of No. 3, Northampton Square, London, E.C., is prepared to advise enquirers, whether employers or employed, male or female,

who are desirous of ascertaining their position under the National Insurance Act. Arrangements can be made for speakers to be sent if desired. Any person desirous of making an enquiry, whether on his own behalf or on the behalf of any other person, or any society or club, should forward a letter containing full particulars and a stamped addressed envelope for reply to the Secretary at the above address. No charge will be made for any information given in response to any enquiry.

The Rousseau Monument.

The 200th anniversary of the birth of Jean-Jacques Rousseau falls on June 28th next, when, it is expected, a feature of the celebrations will be the inauguration, in the Panthéon, of the monument which M. Bartholomé, the sculptor, has just finished.

The Example of Early Rome.

At a meeting of the Midland section of the Institute of Sanitary Engineers, held at the Exchange Hotel, Birmingham, last week, Mr. G. Salway Nicol read a paper describing the methods adopted in constructing the great concrete vaults and domes, the remains of which are to this day conspicuous in and around the Roman Forum. In Roman times, concrete was used in conjunction with brick ribs, as a kind of reinforcement. The water supply and drainage system of Rome was that on which methods of to-day were founded. The ancient city, however, enjoyed a much larger supply of water, and the Roman baths and public buildings in connection with them for the development of physical and intellectual life had nothing approaching them in any modern city. The design, construction, and equipment of these remarkable buildings had much to teach those now working for the improvement of many branches of civic life.

The London County and Westminster Bank.

The directors of the London County and Westminster Bank, Ltd., in submitting to their shareholders the balance-sheet as on December 31st last, report that the net profit amounts to £911,286 18s. 10d., which with £156,229 1s. 10d., the balance brought forward from 1910, leaves available the sum of £1,067,516 0s. 8d. Out of this amount a further dividend of 10½ per cent. (making 21¼ per cent. for the year) has been paid, and, sundry other appropriations having been made, the balance carried forward is £143,766. It is announced that during the past year certain assets of the Birkbeck Bank have been purchased, and a branch, known as the Birkbeck Branch, has been established in the premises. Branches have also been opened at Golder's Green, Leigh-on-Sea, Orpington, and Ramsgate. The head office of the London County and Westminster Bank is at 41, Lothbury, London, E.C., and the bank has agents, correspondents, and branches throughout the United Kingdom, as well as in the principal cities abroad.

COMPETITIONS.

Competitions for Town Planning, Garden Suburb Schemes, etc.

Acting on the recommendation of the R.I.B.A. Competitions Committee, the Council of the Royal Institute give notice that in the case of competitions for town planning, garden suburb schemes, and kindred enterprises, the competition

amongst architects should be confined to the design, and architects should not undertake the erection of the buildings they have designed for competition purposes. Further, the Council are of opinion that members of the Royal Institute should not act as assessors to or otherwise countenance a competition unless it is limited to the design only;

East Sussex Hospital, Hastings.

The awards in this competition are as follows:—1st, No. 6, Messrs. John Saxon Snell and Stanley M. Spoor, London, W. (conjointly); 2nd, No. 9, Messrs. C. K. and T. C. Mayor, Manchester; 3rd, No. 51, Messrs. Adams and Holden, London W.C. The designs will be publicly exhibited in the Drill Hall, Middle Street, Hastings, on February 13th, 14th, and 15th.

New Public Library, Stafford.

The designs for the new public Library at Stafford will be adjudicated upon this week, and the designs will be on exhibition in the Borough Hall, Stafford, on Friday and Saturday next, February 9th and 10th, from 10 a.m. to 9 p.m.

JUNE 28TH. TOWN PLANNING SCHEME, HALE, CHESHIRE.—Schemes are invited by Hale U.D.C., for town-planning in this district, for which premiums of £50 and £25 are offered. Apply to Council Offices, Hale, Cheshire.

THE JUNIOR INSTITUTION OF ENGINEERS.

Visit to Western Electric Company's Works.

A party of members of this Institution, through the kind permission of Mr. G. E. Pingree, managing director, paid a visit recently to the works of the Western Electric Co. at North Woolwich, and spent a most interesting and profitable time in being shown over the various departments, amongst which may be mentioned the milling department, equipped with a large number of milling machines of various types; the punch press department, containing presses of all kinds; the partial assembly department, where various intermediate operations are carried on; a fitters' shop, together with the repair department, under the charge of the factory engineer; the iron-working and tinsmiths' shops; a switchboard frame assembly room; an exceptionally well equipped tool-making room, with its small drawing and inspection offices; drilling and full automatic machinery; condenser department, coil winding room; switchboard cabling department; interior of paper-covering shop; impregnating tanks; motor-driven hydraulic pumps; armouring machine; lead press shop; generating plant in power station; telephone cable stranding shop, with its huge 500-pair stranding machine, and condensing plant. The magnitude of the works impressed the visitors, who were fortunate in seeing the various processes and machinery in operation, and their thanks were expressed by Mr. Walter T. Dunn, chairman of the Institution, to which Mr. G. H. Nash and Mr. Chas. Rice replied; and the visit came to a conclusion.

On February 12th, the Institution is holding a combined meeting with the Architectural Association, to hear and discuss a paper by Mr. Paul Waterhouse, M.A., F.R.I.B.A., on "Bridges," and on February 17th, the Institution's annual dinner is to be held.

NATIONAL FEDERATION OF
BUILDING TRADES
EMPLOYERS.

ANNUAL MEETING IN LONDON.

The annual general meeting of the National Federation of Building Trades Employers was held at the Trocadero Restaurant, Piccadilly Circus, London, on Wednesday last, January 31st, the president, Mr. J. W. White, in the chair.

The chairman, presenting the annual report, referred at some length to the immense amount of work carried out by the Federation in the matter of industrial legislation, particularly with regard to insurance for loss of health, sickness, and unemployment. They had endeavoured to obtain an interview with the Chancellor of the Exchequer, but without result; he thought it was a great pity that they had not had an opportunity for the expression of their views in regard to Part I.

With regard to insurance against unemployment, their reception by the Board of Trade had been everything that could be desired. The Bill, he thought, had been considerably modified as a result of their representations. By the Bill, as it originally stood, all apprentices were included; but now indentured apprentices were excluded. In their interview with Mr. Buxton, one of the chief points raised was: If a joiner was to be included under the scheme, why not a cabinet-maker? Also, if those who were employed for fixing were to be included, why not those who were engaged in the preparation of material? He understood that under the Act, with the exception of the joiner, only those who were actually working on the site would be included.

Mr. Smethurst seconded the adoption of the report, and the motion was carried.

Mr. W. Thomas then moved the adoption of the auditor's report and the accounts and balance-sheet, Mr. Sinclair seconding the motion, which was carried.

Mr. H. F. Higgs put forward a recommendation of the Council for the revision of certain rules having reference to the payment of subscriptions; this was agreed. Certain proposed amendments in the National Form of Contract and a proposal from the Institute of Builders for a form of sub-contract for the use where specialists are made sub-contractors, with consequential amendments to Clauses 20 and 28 of the agreed form of contract, were submitted. At this early stage of the negotiations, and in view of the fact that the sanction of the R.I.B.A. has yet to be obtained, it was deemed inexpedient to make these amendments public.

Mr. Smethurst proposed their adoption, Mr. Blackburn seconding the resolution, which, after considerable discussion, was carried.

Mr. William Shepherd then presented the report of the Employers' Parliamentary Council, the adoption of which was proposed by Mr. Smethurst, who referred to another and similar organisation that had been formed in Lancashire by Sir Charles Macara. Mr. Smethurst suggested that the efforts of the Employers' Parliamentary Council and those of this new organisation might be advantageously co-ordinated, since both bodies sought to attain similar ends. Mr. Woods, of Bolton, seconded the adoption of the report.

Mr. Townsley, of Hull, representing the Yorkshire Federation, put forward a suggestion with respect to the fair wages clause in contracts. In Yorkshire, he

said, the fair wages clause was always incorporated in imperial, municipal, and other contracts, and there was a strong feeling in Yorkshire that master-builders were not advocating their own interests in that connection so well as the trade unions did. He wanted the National Federation to take the matter up, and to procure for them similar protection to that accorded to the trade unions.

Councillor Easten, of Newcastle, suggested that the same conditions should apply equally both to private and public bodies. Further discussion ensued, among those who took part being Mr. Davidson, of Leeds; Councillor Blackburn, of Newport (Mon.); Mr. Whitehouse, of Birmingham; Mr. Cooke, of Preston; Mr. Ambrose, of Bath; and Mr. Locan, of Manchester.

A representative from the Midland Centre then drew attention to the practice of inserting provisional sums in quantities for school buildings, suggesting that the question be referred to the Administrative Committee. This was agreed to.

Mr. Townsley, speaking on the subject of standard wages and the increased cost of living, said that the latter was variously estimated from 1.9 to 10 per cent. He suggested action by the Federation with a view to obtaining reliable data. The motion was seconded by Mr. Rushforth, of Grimsby, and carried.

On the question of the supply of goods to the public on trade terms, Mr. Townsley, representing the Yorkshire Federation, drew attention to the expediency of a closer alliance with kindred trades. He said there could be no two opinions about the necessity for a closer alliance between kindred trades and that Federation. There was in existence a confederation of three or four federations all kindred to the building trade, having a membership of 2,500. The accession of this body would be a great source of strength to the Federation.

Mr. Hopkins, of York, said that if sub-contractors could get a good authority for payment of money due to them, there would be no question of secession. The whole trouble lay there, he thought.

Mr. Cooke said there was a distinct feeling among the smaller trades that if they joined the Federation they would probably be swamped, and that their interests would not receive enough attention.

Mr. Woods, of the Lancashire and Cheshire Federation, put forward some suggestions as to future action with respect to the National Insurance Act. He pointed out that Part I. of the Act ignored builders as business men, and imposed upon them because they had few votes. With regard to Part II. of the Act, he would like to add his congratulations to their secretary and president for the valuable concessions they had obtained from the Board of Trade. Referring to some of the inequalities of the Act, the speaker noted that the commissioners had power to increase the amount of the contribution, both of employees and employer, up to 3½d. per week. He suggested that the question be referred to the Administrative Committee for further consideration and action if deemed advisable. Mr. Matthews seconded the resolution, which was carried.

Mr. Storrs then referred to the proposals to amend certain of the rules of the National Conciliation Boards. It was decided that some of the proposed amendments should be left to the employers' representatives on the Board itself to deal with.

Mr. Sinclair referred to the proposed alteration of Rule 1 of the Conciliation Board by the addition of a clause making it an object of the conciliation scheme to adjust all disputes involving a stoppage of work. Mr. Sinclair also dealt with a proposal by the operatives to restrict the scope of the scheme by excluding disputes between unionists and non-unionists. If, he said, they employed unionists only would they—the unionists—guarantee to work only for federated employers?

After considerable discussion by Mr. Moss, Mr. Cooke, Mr. Matthews, Mr. Storrs, Mr. Moffatt, Mr. Long, and Mr. Smethurst, the following resolution was carried: "That the Administrative Committee be requested to circularise each branch association throughout the Federation, asking them to consider the question of the action of trade union workmen in claiming the right to refuse to work with non-unionists; and to say if the settled opinion of the association is that the right of the employer to employ whom he will, and for the workman to work for whom he will, shall, as far as possible, be maintained; and, if necessary, they will support the Federation if they desire to fight this issue. And it be an instruction to the Administrative Committee to issue a memorandum reviewing the position, and to send it out with the former request."

Proposals by the N.A.O.P. for the amendment of Rules 1, 2, 3, 4, and of the joint agreement between the N.A.M.P. and the N.A.O.P. were considered.

Mr. Cooke moved a resolution to the effect that while there was something to be said for the proposal to alter Rules 2, 3, and 4, the proposal to alter Rule 1 and to insert a new clause, should be opposed.

Mr. Lindley seconded the resolution which was carried.

The elections by federations for the new Executive Council having been announced, and certain other business having been transacted, the retiring president said he had great pleasure in proposing Mr. James Wright, of Nottingham, as President for the new year. No one, he said, was more deserving of the honour than Mr. Wright.

Having been invested with the chair of office, Mr. Wright said he did not undervalue the honour they had done him, but he accepted it with a good deal of diffidence. The position was one of great responsibility, and it had been very ably filled in past years. He would, however, do his best to fulfil the duties entrusted to him.

On the invitation of the Midland Centre it was then decided to hold the summer meeting at Nottingham.

Mr. Ernest J. Brown then proposed a vote of thanks to Mr. A. G. White for his whole-hearted service to the Federation.

Mr. J. W. White seconded the motion which was heartily supported by Mr. George Macfarlane and several other gentlemen.

Mr. A. G. White briefly replied.

MODERN HOUSE PLANNING.

A paper on this subject was read by Mr. A. G. R. Mackenzie before last week's meeting of the Architectural Association but owing to the pressure on our space are obliged to hold over our report next week. Among those who took part in the discussion that followed the reading of the paper were: Mr. G. Jenkins, Mr. H. H. Wigglesworth, Geoffrey Lucas, Mr. H. V. Ashley, and Mr. Curtis Green.

Inigo Jones and the Whitehall Palace.

AT the meeting of the Archæological Institute on the 7th Mr. J. A. Gotch read a remarkable paper on the subject of "The Original Drawings of the Palace of Whitehall attributed to Inigo Jones." The meeting took place at the rooms of the Society of Antiquaries, Sir Henry Loworth in the chair. Mr. Gotch has made an exhaustive study of the various drawings existing for the Whitehall Palace. These are curiously dispersed, some of them being in the Chatsworth collection, some at Worcester College and elsewhere, and drawings referring to the same design are at places far apart. It was only by the aid of photography that it was possible to put some of these dispersed drawings together and examine them collectively. One result is that there are in all seven different designs for a Whitehall Palace in existence, and that none of these can be positively traced to Inigo Jones as their author, all those which are signed bearing the signature of his pupil and devoted admirer William Webb. Two of the plans, one of them the well-known one always attributed to Inigo Jones, have the feature of the great circular court which is the finest point in the plan. It does not appear, as far as one could follow out the rather intricate argument of the paper, that any doubt is thrown on the authorship of the Banqueting-house now existing; we are still to regard that as the design of Inigo Jones, although we believe that as a matter of fact not much of the original masonry of the arcade remains, the records of the Office of Works showing that it has been extensively renewed and patched up at different periods. Webb had filled the post of Deputy-Surveyor during part of the lifetime of Inigo Jones, and in his application for the surveyorship under Charles II. referred to this fact to support his claim. Mr. Weaver, in the discussion which followed the paper, said that he either declined merely to accept the statements of Webb as to his former position; at all events they needed corroboration from some other source. Mr. Gotch appears to think that his investigations have finally disposed of Inigo Jones's claim to the great plan of the palace. It seems to us that what he has proved is only that there are no actual drawings of it by Inigo Jones. Does it follow, from that, that the conception of it was not his? Webb lived in intimacy with Inigo Jones, was constantly working under him, and had the most enthusiastic admiration for him. Is it not quite possible that in making the plan signed with his name he was working out a scheme which originated with his master? There is nothing beyond this plan, if it were his, to show that Webb was a remarkable architectural genius; the elevations which may be admitted to be his are poor and commonplace, and show none of that nobility of Classic style which characterises the Banqueting-house. The conclusion, to our minds, is that Webb was working on Inigo Jones's ideas. There is a curious parallel to this in the history of music. It is known that Mozart's last and in the respects greatest work, the "Requiem," was only half written by him, and was completed by his pupil Süssmayer; we now know exactly where Mozart's writing ends, and Süssmayer's goes on. But no one doubts that in the finest parts of the latter portion Süssmayer must have been working on ideas derived from his master, as none of Süssmayer's

acknowledged works give any such evidence of genius. Süssmayer was to Mozart exactly what Webb was to Inigo Jones—a trusted pupil and collaborator, with an ardent admiration for his master. It is a curiously parallel case, and it is not unreasonable to conclude that the explanation is the same in both instances. We may on that supposition still regard the grand plan for Whitehall Palace as being essentially the suggestion of Inigo Jones's genius, though put on paper by his pupil, and signed by him as the actual executant of the drawing. The paper as a whole will, we presume, be printed in the Transactions of the Archæological Institute, with reproductions of the various drawings, when we may have more to say about it. We should have expected that a paper like this, which concerns the work and to some extent the reputation of the greatest English architect, would have been read to the Institute of Architects rather than to an archæological society. Its main interest is certainly architectural.

Architectural Drawing.

PROFESSOR BLOMFIELD has taken for his four lectures on Architecture to the Academy students the interesting subject of "Architectural Drawing," a subject which deserves more serious treatment than it has generally received. He commenced by advising students to take the work of past days as a test or example, rather than to follow the fashion of the moment. Work which had retained its importance and interest through a considerable lapse of time afforded a more certain standard, and could be better judged than that which was only the fashion of the present day, and might or might not have permanent value. Some of the present fashions in architectural drawing were, he thought, by no means good; there was a want of that care and certainty of delineation which characterised the drawings of an older school; and he especially deprecated the modern habit of drawing in portentously thick lines, which he believed was fostered a good deal by the influence of competitions, and the desire, in a competition elevation, to give it what was supposed to be a force and vigour that would ensure its not being overlooked. The result of this thick-line drawing was not only inartistic; in view of the use of drawings by a contractor it was highly impractical, rendering accurate measurement of a drawing very difficult. It may be replied, of course, that contract drawings always have (or should have) figured dimensions, which are to be followed in preference to scale measurements; but as to the inartistic effect of this style of drawing, we are quite in agreement with the lecturer. In regard to the ancient use of drawing in connection with architecture, Professor Blomfield thought it was quite impossible that the carefully refined proportions of Greek buildings could have been set out without very careful drawing first, but there was no record of such drawings, and very little of any drawings prepared for mediæval buildings; if made, they had not been preserved. (There is, however, the instance of the large mediæval drawing of the spire of Cologne Cathedral, which was preserved, and was, we believe, made use of in the completion of the front in modern times.) After

showing a drawing of Piranesi's from the "Carcere" set which represented, he said, "the last word in architectural drawing." Professor Blomfield went on to speak of the only mediæval architect who had left a sketch-book behind him, Villars de Honecourt, whose drawings had so fascinated Burges that he proceeded to produce a sketch-book of his own in somewhat the same style. A good number of Villars de Honecourt's sketches were shown by the lantern, with their strange mingling of practical diagrams of planning of all kinds, of sketches of men and animals on the same sheets; anything that came into his head having apparently been put down, however incongruously, on the sheet he happened to be using at the time. The archaeological or historical interest of these strange medleys of draughtsmanship is undeniable; they help to let us see the point of view of the Middle Ages; in other respects, we think a little too much has been made of Villars de Honecourt. The subjects of the other three lectures are thus distributed: on Thursday the 8th, "Some draughtsmen of the sixteenth century—Bramante, da Sangallo, Du Cerceau, De l'Orme"; on Monday the 12th, "French draughtsmen of the seventeenth century"; and on Thursday the 15th, "Italian draughtsmen of the eighteenth century, and Piranesi."

The Soane Awards.

AT last week's meeting of the Royal Institute the President, Mr. Leonard Stokes, delighted everyone by the short address in which, with a great deal of quiet humour, he told the story of his "mistakes" in student days. Mr. Horsley gave a good and thoughtful criticism on the students' designs, and the prizes were afterwards delivered, but we cannot help thinking that a mistake has been made in the matter of the Soane Medallion. When we reviewed the designs we remarked that there was an idea afloat that the Medallion would not be awarded this year; we thought it doubtful whether the designs were up to a level that ought to justify the award; but we were of opinion that the only design to which it could be awarded was that signed "Vista." The Council or the examining committee took a different view, and placed "Vista" third, giving the author an Honourable Mention, but dividing the £100 equally between two other competitors. The surprising point was that, in spite of this award, Mr. Horsley's analysis of the designs decidedly gave the best praise and least fault-finding to "Vista." Why, then, was the author of this design not placed first? The review of the designs was at variance with the decision shown in the awards—it practically confirmed our previously expressed opinion; and we do not think the author of "Vista" has been quite fairly treated. He certainly produced the plan best suited to the problem put before the students, and the one with fewest defects in it.

The Society for Roman Studies.

THE first number of the "Journal" of this Society has just been issued, dated 1911, for it has been delayed in publication. It contains various important articles on Roman subjects, commencing with a long analysis by Mrs. Strong of the exhibition which has been installed in the area of the Thermæ of Diocletian to illustrate the provinces of the Roman Empire. The article forms a kind of summary of the history of Roman conquest, influence, and remains in the various countries outside of Italy which were dominated by the Empire. The exhibition, which was arranged as a part of last year's art exhibition at Rome, is to remain open and unaltered till at least the end of April, so that there is still time for those to see it who were not able to visit Rome last year. Even apart from seeing the exhibition, Mrs. Strong's article on it is worth studying as a *résumé* of the history of Roman rule in conquered countries. In an article on "Coins from the neighbourhood of a Roman mine in Spain" mention is made of an interesting discovery, in the lower workings of the mine, of a set of pumps of the

Roman period, evidently for the purpose of emptying the mine when flooded. They consisted of a series of "Archimedean" screws (spiral pipes wound round a cylinder superimposed in single sets, each set being provided with a tank or cistern into which the water flowed from the lower set, and from which it was lifted by the "screw" to the cistern above. Whether the authors of the article, who are archaeologists and not engineers, are justified in saying that these pumps "presuppose a knowledge of the laws of physics and a mastery of mathematical calculations of the highest order" may be doubted; a scientific mechanician would perhaps be less enthusiastic over them; but a discovery of mechanical contrivances of great antiquity is always of interest. An article on "The Catacombs of Callixtus in the light of recent excavations" gives the latest information on this collection of early Christian mortuary chapels, as they may be called, with a plan, and a photograph of the interior of the "Crypt of the Columns" with a column in each of its angles. The "Journal" is supplemented by a large number of plates, photographs, Roman sculpture and other objects.

The Essence of a Hollow Square.

WHEN the interpretation of ill-drafted by-laws is complicated with Scottish metaphysics, the conclusions reached are often such as those that are apt to emerge from the argument in Savoy opera. The other day the Scottish Court of Session was required to determine what was a hollow square. Hazy notions on this subject seem to have persisted from the time of Artemus Ward, who, upon a momentous occasion, "formed himself in a hollow square to resist the charge of the enemy." The Dean of Guild of Glasgow had refused permission to erect a building "within the enclosed space of back ground in a hollow square," and the applicant had appealed. In delivering judgment on the appeal, in the Court of Session the Lord President had some pleasantly ironical things to say about the Glasgow Corporation Act, of which the essence of the provisions was in question. In many ways, he said, these provisions were not models of draughtsmanship and they had had the peculiar result, he thought, that some of them were clearly unworkable, and that others would put with extraordinary hardship on certain individuals, practically making them, at their own expense or by confiscation of their ground, subscribe for a general benefit, whereas others, who were more fortunate, and who had done more to obstruct ventilation and so on than they had, would go scot free. If, he said, "the Corporation of Glasgow chose to have legislation of this sort, it was quite competent that their lordships, whatever they might think of it, had no option but to apply the words as they found them." As to the definition of a hollow square, he thought that the draughtsman of the Act came to grief between two stools. He naturally "wished to have something which could be equally applied to a hollow square which was only in the course of construction, and which could not be said to be a hollow square now; he also wished it to apply to an actual hollow square even although that hollow square was in many respects not hollow." We gather that the gentleman was between two stools. No doubt he will do better next time, after digesting the Lord President's ultra-philosophical explanation of the essence of a hollow square, as follows: "The essence of a hollow square was that it had got to be formed by streets—no doubt streets with buildings, the fronts of those buildings to be the streets; and then the backs of them were to be the space of what was called back ground. The square, which need not be a square at all, simply meant any continuous geometrical figure, the bounding line of which was formed by a set of streets which without any street piercing that geometrical figure. There was no definition of back ground, and one had to adopt the suggestion that all that could be said about back ground was that it was whatever was not front ground. From this luminous exposition it is clear that a hollow square *in posse* is not a hollow square *in esse*; that a ho-

THE GUARD HOUSE, BERLIN. KARL FRIEDRICH SCHINKEL, ARCHITECT.

square within the meaning of the Act (through or round which, perhaps the customary "coach-and-six" could be driven) is formed of streets, the fronts of buildings being streets, while their backs are space called back ground; that the square need not be a square; and that back ground is not front ground. With these data to guide him, the most muddle-headed of draughtsmen will have no excuse for going wrong.

A Study of Schinkel.

IN view of the fact that the neo-Grec style is receiving much attention at the present time, being regarded in some quarters as the means towards a truly national architecture, it is opportune that an article on so talented an exponent as Karl Friedrich Schinkel should appear in the February issue of "The Architectural Review" from the pen of Mr. A. E. Richardson. That Schinkel was a great architect is testified by such fine buildings as the Old Museum and the Guard House in Berlin, both of which display a true appreciation of Classic art blended with modern feeling. As Mr. Richardson says, Schinkel realised that to excel in architecture as one of the arts of design it was necessary to cultivate the others, if not in equal, at least in a secondary degree. Cockerell thought the same, and, in consequence, the architecture of both masters exhibits similar qualities. Schinkel's strictly architectural career may be said to date from 1810, in which year he was appointed one of the newly established Building Committee, and became a member of the Academy in Berlin. In 1816 he was commissioned to design a cathedral in commemoration of the general peace following the Napoleonic wars, but the design was for some reason abandoned. Next followed an inquiry into the condition of the fabric of Cologne Cathedral, which Schinkel completed in the same year; and in 1818 he erected in Berlin the Royal Guard House—his first building

of monumental character. Nothing could be more daringly original than his design for this building, the main façade of which consists of a hexastyle Dorian portico subordinated between pylons. "Not content with a mere reproduction of a Greek temple, he contrived an original composition, expressive of its purpose, full of character, and, in its rugged simplicity, eloquent of resistance and security. He disdained pedantry, and even eschewed the ordinary treatments of triglyphs for the decoration of the frieze; but he realised the need of a vertical *motif* in this feature, and substituted small 'victories' to obtain his contrasting lines."

In 1818 Schinkel also designed the new Schauspielhaus, or Royal Theatre, in Berlin. The exterior of this building is marred by the lack of proper subordination between the two pediments forming the centre feature of the main front, but the interior is very finely treated, an apartment of special interest being the concert hall, in connection with which it is safe to say that, with the exception of the small concert room at St. George's Hall, Liverpool, there are few extant of equal merit.

The Old Museum—Schinkel's masterpiece—occupied the architect for six years, from 1823-9. It is a building notable for its magnificent loggia of Ionic columns on the main elevation and for its great rotunda, or sculpture hall, the design of which is a version of the Pantheon.

Of the many other buildings which Schinkel erected, Mr. Richardson gives an extended account, the article being very fully illustrated, and in that respect of special value.

Other features of the February issue of the "Review" are some splendid drawings of Roman buildings by Mr. Walcot and an article on "The New Exchange in the Strand," by Mr. Godfrey, while current work is represented by the Regent Street Polytechnic, the Campbell-Bannerman Memorial in Westminster Abbey, and a fine chair and a floor memorial by Sir Robert Lorimer.

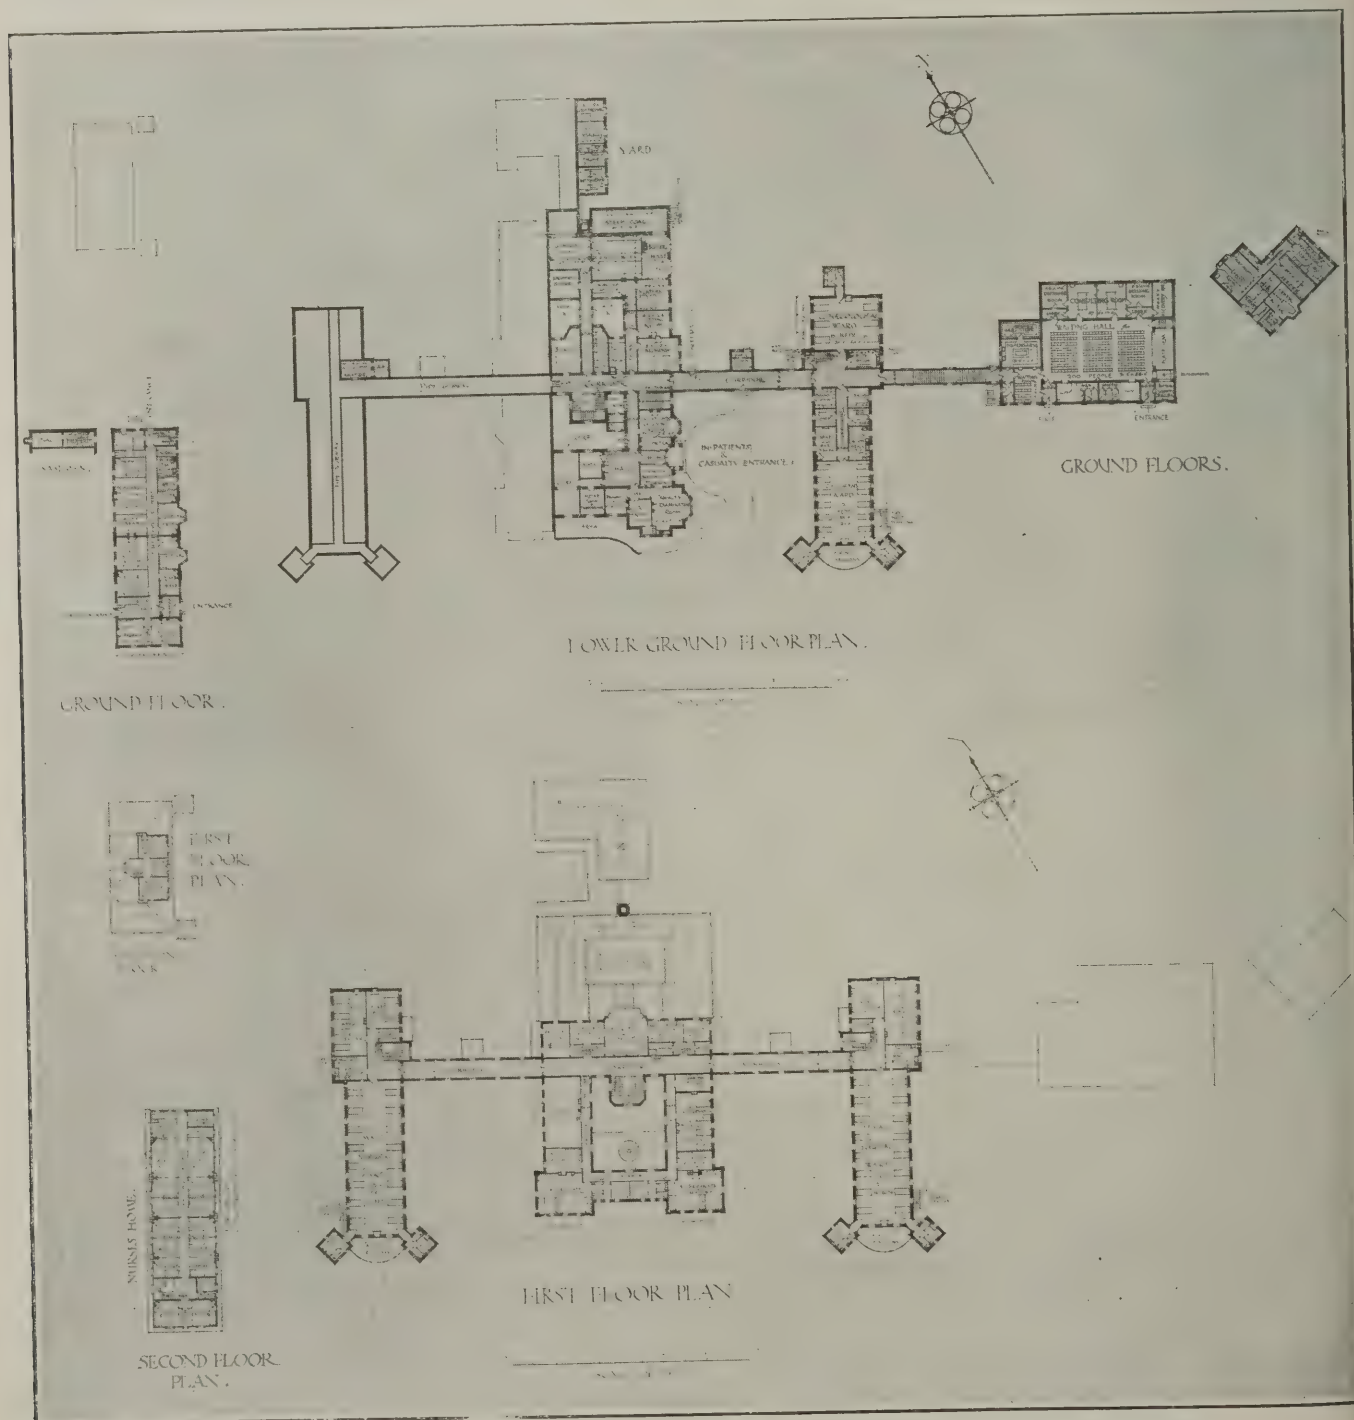

EAST SUSSEX HOSPITAL
COMPETITION

The East Sussex Hospital, on the front at Hastings, having outgrown its accommodation, and its situation having become less suitable by reason of the noise of the electric tramway and the increased traffic, it has been decided, as a memorial to King Edward VII., to erect a new hospital on a more commodious site at the corner of Bohemia Road and Cambridge Road. An open competition was instituted, with Mr. Edwin T. Hall, F.R.I.B.A., as assessor, and, as announced in our issue for last week, the following award has been made: 1st, No. 6, Messrs. John Saxon Snell and Stanley M. Spoor (conjointly), of London, W.; 2nd, No. 9, Messrs. C. K. and T. C. Mayor, of Manchester; 3rd No. 51, Messrs. H. Percy Adams and Charles Holden, of London, W.C. These

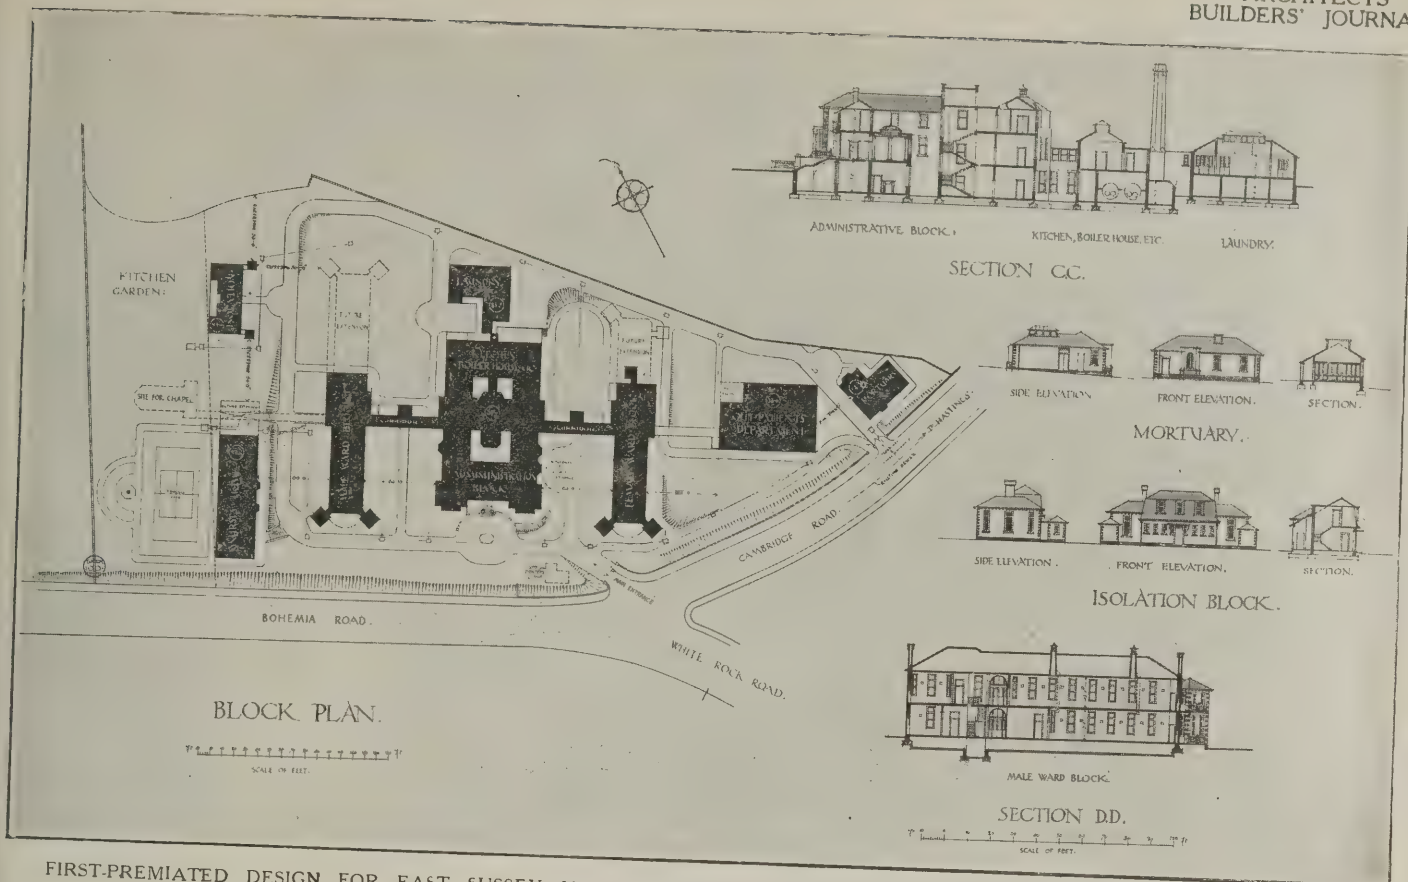

three designs we are able to illustrate in the present issue. All the designs submitted in the competition are on exhibition this week in the Drill Hall, Middle Street, Hastings, from Tuesday, the 13th, till Saturday, the 17th. The hours of admission are from 10 to 5, except Saturday, on which day the exhibition is open from 10 to 7.

The instructions issued to competing architects stated that the following requirements were essential: No building to be more than 15 ft. high, nor any isolation ward used for infectious cases to be erected on that portion of the property coloured green on the plan—that is, within 100 ft. of the north boundary wall. No building to be erected within 20 ft. of Bohemia Road. The hospital to contain 100 beds in the in-patient department, the buildings being so arranged as to be capable of extension in the future, and to be on the pavilion principle.

The plans to include in-patient hospital, out-patient department, nurses' home, isolation block, mortuary, p.m. room, laundry, outbuildings, and site only for chapel. The in-patient and out-patient department to be connected by covered way with the administrative block. The nurses' home to be a separate building with external entrance to the hospital without necessitating nurses to pass through the administration block. The in-patient pavilions to contain 5 main wards, and each to have one or more smaller wards in connection with it. Sister's separate room not required. The out-patient department to have a waiting hall to seat 200 with small platform (which could be used for meetings of governors, lectures, etc.), a consulting room at least 26 ft. long and divisible into two rooms by folding doors, two dressing rooms, recovery room, lavatories, porter's room or office.

FIRST-PREMIATED DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS. JOHN SAXON SNELL AND STANLEY M. SPOOR, ASSOCIATED ARCHITECTS.

FIRST-PREMIATED. DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS. JOHN SAXON SNELL AND STANLEY M. SPOOR,
ASSOCIATED ARCHITECTS.

The following suggestions, among others, were made by the hospital committee: Teak floors for wards, terrazzo for corridors, etc.—all to have concave skirting. Sash windows (deep ledges hinged for lower part and hopper-hung windows above). Hollow walls, with special bricks for facing. Eye wards to have a north, or not sunny, aspect. Outside iron fire-escape staircases to all buildings of more than one storey, unless internal staircases are provided at each end. Balconies to the 5 wards to admit beds easily. Sanitary towers to wards built out from main blocks, with connecting passage well ventilated. Heating by hot-water radiators. Wards would have better appearance without centre block for fireplaces, but latter may be shown if thought desirable. Fireplaces at end or side of wards.

The following extracts are taken from the report accompanying the first-premiated design by Messrs. Snell and Spoor, illustrated on the centre plate in this issue:—

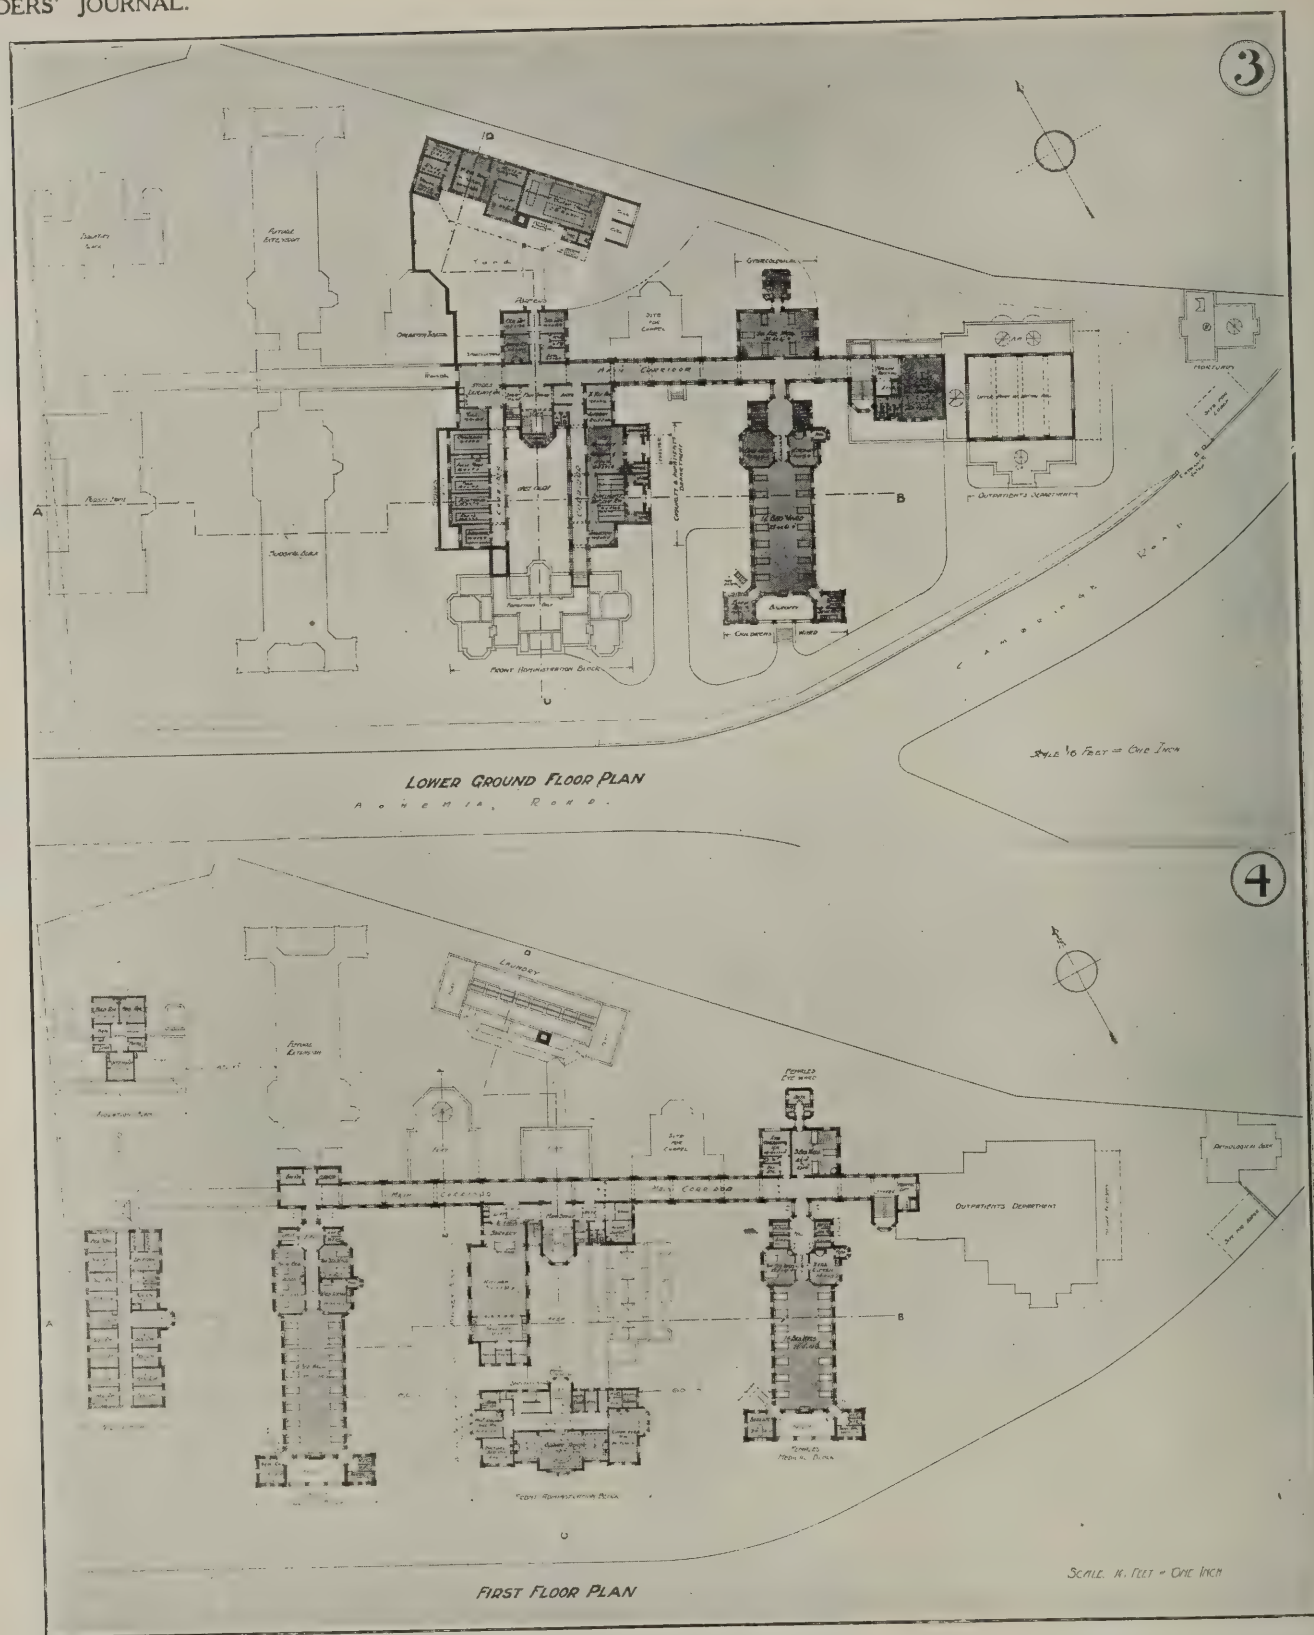

"The very great fall in the ground from west to east, the desire to keep the administration central, and the very definite instructions as to the provision of one lift only to serve all floors have necessitated the two or three floor corridors; it is hoped, however, that the provision of blow-throughs between each floor may be considered a satisfactory solution of an arrangement which otherwise might be considered regrettable. . . . The male and female ward blocks of the in-patient hospital call for little comment, and are of the usual pavilion type. The diversity in the units of each class of patient has presented some difficulty, and the design, especially of the smaller units, shows a lack of symmetrical arrangement which will no longer obtain when the hospital is enlarged. The surgical wards have been placed on the top floor in each pavilion for easy and level com-

munication with the operating room. The cubic contents of the wards allow each patient 1,400 ft. and upwards, children receiving a little over 1,000 ft. In the administration block two entrances have been provided, that on the ground-floor level being intended for the use of officers of the institution, the committee, and public visitors; the other, on the lower-ground floor, serving for in-patients, their visitors, and also for casualty cases. The main staircase and lift are placed centrally to serve the upper, lower, and middle corridors; it serves the operating room direct, and is also opposite to the service from the kitchen, and in the basement to the coal supply; it is of sufficient size to carry a bed with lift attendant and nurse. The isolation block is at the north-west angle of the

site, and allows 2,000 cubic ft. to each patient. The nurses' home is as far from the hospital buildings as the restrictions of the site will permit, and has a garden and tennis court adjoining. The mortuary is at that portion of the site which is farthest from the ward blocks and nearest to the town, being screened by the out-patients' department. The laundry is at the rear of the kitchen and offices, and is attached thereto by a covered way. A lower storey comprises disinfector, destructor, and a small steam engine for driving the laundry plant. As regards ventilation, electric fans will be provided in the operating room and the washhouse, while an ample number of inlets and outlets will be relied on for the ventilation of the remainder of the building. The inlets generally will be fixed

SECOND-PREMIATED DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS. C. K. AND T. C. MAYOR, ARCHITECTS.

about 7 ft. above the floor lines, and the outlets as near the ceilings as circumstances permit. Lighting will be by electricity, with emergency gas jets at different points, and heating will be effected by open fireplaces and low-pressure hot-water radiators. As regards the building itself, the walls generally are intended to be built hollow (except in protected places) in stock bricks and red facings and brindled brick quoins and dressings. In the ward blocks the floors of the wards will be of teak, the duty rooms being covered with linoleum on

cement, and terrazzo elsewhere. Indicated on the block plan are the maximum amount of ward extensions contemplated. After allowing for the displacement of existing ward units on the north side of the main corridor, due to the proposed enlargement, the net number of additional beds would be approximately as follows: Male ward block 32 beds, female ward blocks 32 beds. The cost is estimated at £43,783. This is in excess of the amount which competitors have been given to unders*and is at present available, but some very expensive finishings (teak

flooring and joinery, for instance, and a very liberal cubic allowance for a country hospital) are demanded, and therefore provided, but the cost of future extension has been very largely met in the present very ample accommodation—in many cases no further structural alterations being required at all; with the result that the cost of the completed hospital will average very considerably less per bed unit."

The estimate for the design placed second is £47,376, and for that placed third £36,889.

COMPETITIONS.

New Public Library, Stafford.

The awards in this competition are as follows: 1st, Messrs. Briggs, Wolstenholme and Thornely, Liverpool; 2nd, Messrs. Sutton and Gregory, Nottingham; 3rd, Messrs. Castle and Warren, London, W.C. Mr. Henry T. Hare, F.R.I.B.A., was the assessor. No fewer than 210 designs were submitted for this library, which is to cost £4,000. The designs were exhibited at the Borough Hall, Stafford, on Friday and Saturday last.

The New Legislative Buildings for Winnipeg.

The Government of Manitoba recently invited the Royal Institute of British Architects to appoint an assessor of the designs for their new Legislative Buildings at Winnipeg, which are to cost \$2,000,000 (about £411,000). The Institute, in recognition of the compliment conveyed in the request, asked their president, Mr. Leonard Stokes, to undertake the task, which he has agreed to do. Mr. Stokes, on his arrival in Canada at the beginning of April, will examine the sketches submitted in the preliminary stage of the competition. From those he will select the six most suitable for the purpose, and during a return visit to Winnipeg in the autumn will make his final choice from the completed plans sent in in the meantime. The competition is open to all British architects. The preliminary sketches have to be received in Winnipeg by the end of March. Substantial prizes will be given for the best six, whose authors will then be invited to send complete plans.

LIST OF COMPETITIONS OPEN.

FEBRUARY 17TH. NEW OFFICES FOR THE PORT OF LONDON.—The Port of London Authority invite preliminary sketch designs for new head offices in Trinity Square, and for lay-out of a building site. Sir Aston Webb, R.A., is the assessor.

FEBRUARY 17TH. ELEMENTARY SCHOOL, YORK.—The City of York Education Committee invite competitive designs for a public elementary school to be built in Camplashon Lane, Bishopthorpe Road. Assessors, Messrs. T. Mellard Reade and Son, Liverpool. Apply, J. H. Mason, secretary, Education Offices, Clifford Street, York.

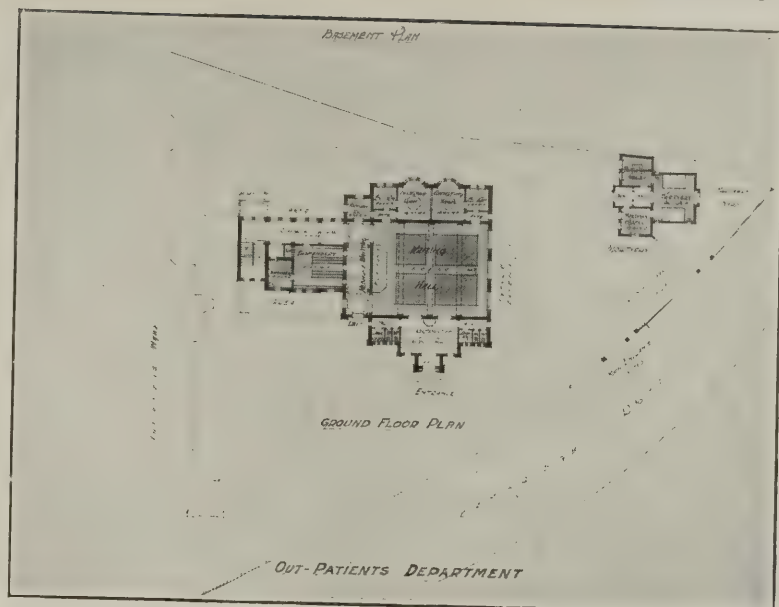

MARCH 15TH. LAYING OUT ESTATE, PRESTATYN.—Designs for laying-out the

Prestatyn Estate are invited. Premiums of £50, £30, and £20. Application (with 19s. 6d. deposit, returnable) was to be sent by January 8th to Lord Aberconway and the Trustees of the Prestatyn Estate, 33, Henrietta Street, Strand, W.C. Designs by March 15th. Judge, Mr. H. V. Lanchester, F.R.I.B.A.

MARCH 16TH. PUBLIC OFFICES, HARROW.—Harrow-on-the-Hill Urban District Council invite designs for enlargement and alterations of their public offices, at a cost not to exceed £4,500. Premiums, thirty, twenty, and fifteen guineas. Plan and instructions (£1, returnable) from Mr. J. Percy Bennetts, Engineer and Surveyor to the Council, Council Offices, Harrow-on-the-Hill. R.I.B.A. will be asked to appoint an assessor.

MARCH 25TH. SCHOOL, COLCHESTER.—The Borough of Colchester Education Committee invite architects practising within the borough to send in Competitive Plans for a School for about 750 children, to be erected on a site in Hamilton Road, Colchester. Plans must be delivered by 12 o'clock noon on March 25th. Apply to Ernest H. Bultitude, Clerk, Education Offices, 8, East Stockwell Street, Colchester.

MARCH 31ST. NEW PARLIAMENT BUILDINGS, WINNIPEG.—Regulations governing the competition for the new Parliament buildings for the City of

SECOND-PREMIATED DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS.
C. K. AND T. C. MAYOR, ARCHITECTS.

Winnipeg may be had from the High Commissioner, for Canada, 17, Victoria Street, Westminster. [The date formerly announced for the close of this competition has been extended to March 31st. Mr. Leonard Stokes, P.R.I.B.A., has been appointed assessor.]

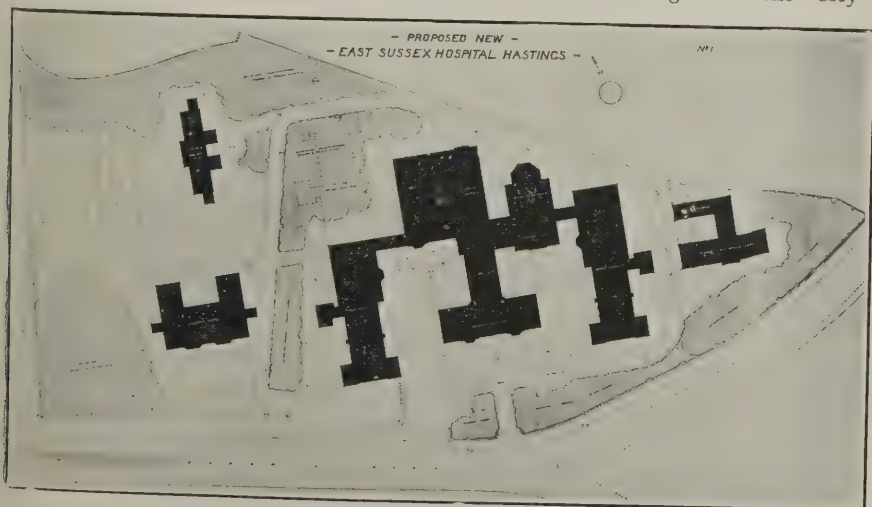

APRIL 4TH. COUNCIL OFFICES, PORTLAND.—Portland U.D.C. offer premiums of £50 and £10 respectively for first and second designs. Particulars (deposit 10s. 6d., returnable) from R. A. Cole-nutt, Clerk to the Council, Offices, New Road, Portland.

APRIL 20TH. BIRMINGHAM BLUE COAT SCHOOL.—Competition strictly limited to Birmingham architects. In a preliminary competition, three designs will be selected, and the authors will be paid £50 each to develop and redraw their plans to a larger scale, showing further details. In the event of the Governors failing to proceed with the second competition, the authors of the three designs will be paid £25 each. Assessors, Mr. G. H. Hunt, F.R.I.B.A., of London, and Mr. Charles E. Bateman, F.R.I.B.A., hon. consulting archt. to the Governors. Drawings to be delivered by mid-day of April 20th to Mr. William E. Bolton, Secretary, The Blue Coat School, Birmingham.

JUNE 28TH. TOWN PLANNING. Hale. —Premiums of £50 and £25 are offered for a town-planning scheme.—Address Council Offices, Hale, Cheshire.

AUGUST 30TH. THE HENRY SAXON SNELL ESSAY.—The Henry Saxon Snell prize of fifty guineas and silver medal of the Royal Sanitary Institute is offered for an essay on "Suggestions for Improvements in the Ventilating, Lighting, Heating, and Water Supply Appliances and Fittings for an Operating Room and its accessory rooms for a General Hospital of 400 Beds (no Students)." Essays (in which two competitors of different professions or crafts may join) to be delivered before 4 p.m., August 30th, to the Secretary, Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., from whom full particulars may be obtained.

NO DATE. ELEMENTARY SCHOOL, WARRINGTON.—The County Borough of Warrington Education Committee invite designs for the erection of a public elementary school. Deposit, £1 is. (returnable). Apply J. Moore Murray, Secretary and Director, Education Office Sankey Street, Warrington.

THIRD-PREMIATED DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS.
ADAMS AND HOLDEN, ARCHITECTS.

CORRESPONDENCE.

*What the Building Trade Wants.**To the Editor of the ARCHITECTS' AND
BUILDERS' JOURNAL.*

SIR,—I have read with much interest the articles in your recent issues upon the education and status of employers in the building trade, and the possible governing functions of the Institute of Builders in connection therewith.

I entirely agree with your correspondent who pointed out that public opinion needs to be educated upon the matter. Until it is recognised that the person who sells a badly built house is just as fraudulent and criminal towards his fellow-citizens as one who retails unwholesome food, we cannot hope for the conferment of any powers such as would be necessary to establish the restrictive and governing action you foreshadow, and such as was exercised by the trade guilds from the fourteenth to the seventeenth centuries.

The information you print as to what is obtaining in Germany is particularly interesting. We have a good deal to learn from our friends across the North Sea; but in the matter of public facilities for technical education, both of workmen and those who direct them, it is a pleasing fact that the opportunities open to the present-day youth, in London at any rate, are tremendously in advance of those available during the pupillage of,

Yours faithfully,

Station Works, F. HIGGS.
Hinton Road,
Herne Hill, S.E.

PICTURE EXHIBITIONS.

Messrs. Tooth and Sons' Gallery.

At this gallery there is a collection of paintings by the late Josef Israels, which enables one to compare his style in early and late periods of his work. The first picture in the catalogue, "The Widow," is the last he ever painted, a month or two before his death. It represents the widow and her children driving the cow to pasture, in a very sombre landscape; but it is evident that when he painted this his hand and eye were failing, as far as execution is concerned. The most important picture in the collection, the interior called "The Anxious Family," is in the artist's finest style; he painted a smaller replica of it in a neater and more finished style, which is in the same room; it looks like an earlier work in regard to style of execution, but is probably not; Israels was rather given to painting smaller repetitions of his important pictures. We should take it that the solidly painted head of "A Fisherman" is an early work, before the painter had come to his real style. "A Friendly Visit," on the other hand, illustrates rather too strongly the artist's later tendency towards sombre and gloomy tone of colour in his interior scenes. Some of the small open-air scenes are refreshingly bright and sparkling, especially "Swimming the Dog," a breezy little landscape which one would hardly have taken for Israels'. The exhibition is a very interesting one.

The Goupil Gallery.

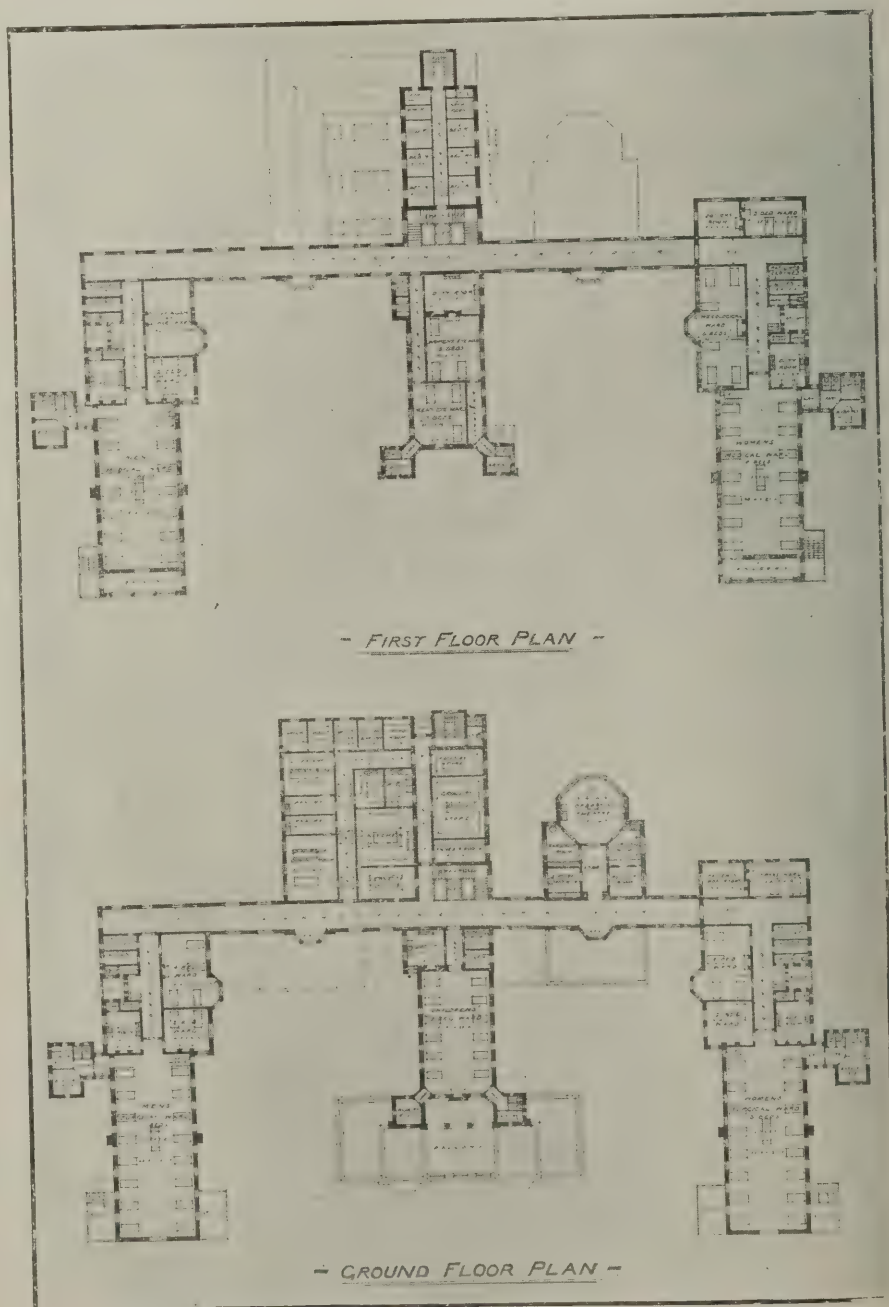

There is an exceedingly interesting exhibition at the Goupil Gallery of the works of a very talented painter, the late W. Christian Symons, who never enjoyed in his lifetime the success or reputation

which his talents certainly merited. His water-colours, especially the landscape sketches, show a great freedom of style and knowledge of open-air effect; witness "A Sussex Sky," "The Old Cannon," "Cloud Study," "The Thames at Chelsea." Mr. Symons carried out some mosaics for Westminster Cathedral, some of the studies for which are here, but do not impress us very much; they are in an assumed mediæval style with which we have not much sympathy; but they are things better judged of in execution as mosaics than in small-scale water-colour studies. The oil-pictures are not so good in point of style as the water-colours; there is a dry *facture* about them, which reminds us of the same quality in the late Mr. Charles's pictures; and possibly it may be that this quality, which does not tend to make pictures generally attractive, may have had something to do with the want of popular success of both painters. The landscape called (from the foreground figures) "Little Boy Blue and Red Riding Hood" is a capital landscape in composition and in open-air effect, but it is, owing to this dry manner of execution, somehow

wanting in charm. There are a good many clever and interesting things among the oil-paintings, however, including what may be taken to be a portrait group of children ("The Young Electricians"); and the whole exhibition leaves the impression of being the work of a painter of exceptional ability.

The Carfax Gallery.

We so often find the Carfax Gallery the depository of works that may be described as more curious than beautiful that it is a gratification to find in the exhibition of landscapes by Mr. Elliott Seabrooke a set of pictures and studies in which one can really take pleasure. His best powers seem to lie in seizing the composition and sentiment of stern and rugged mountain scenery, as in painting the solid rampart of "Rainsbarrow" and the dark sloping masses of "Langdale Pikes." "The Icknield Way," a snow-scene with a sky of remarkable power, is another impressive painting. Some of the small studies of landscape, in low tones or in monochrome, are very interesting, and they all show a distinct feeling for landscape composition.

THIRD-PREMIATED DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS.
H. PERCY ADAMS, F.R.I.B.A., AND CHARLES HOLDEN, A.R.I.B.A., ARCHITECTS.

OBITUARY.

Mr. William Glover, F.R.I.B.A.

At the last meeting of the R.I.B.A., held on February 5th, Mr. Henry T. Hare announced with regret the decease of Mr. William Glover, Fellow, elected 1899. Mr. Glover was a past-president of the Northern Architectural Association, and represented that body for a time on the Council of the Institute. He was well known for his generous gifts and benefactions to the Northern Association, to the Architects' Benevolent Society, to the King Edward VII. Hospital at Windsor, to the Laing Art Gallery, Newcastle, where he founded a fund for the purchase of works of local artists, and to various other institutions, educational and charitable. Mr. Glover, who retired from practice about twelve years ago, was eighty-two years of age.

The decease was also announced of Mr. Francis William Humphreys, Associate 1880, Fellow 1892, and Mr. John Todd, Associate 1880.

Dr. David Christison.

By the death of Dr. David Christison, which occurred recently, at his residence, 20, Magdala Crescent, Edinburgh, Scotland loses one of her foremost antiquaries. He was born in Edinburgh on January 25th, 1830, so that he had nearly completed his 82nd year. After taking the degree of M.D. at Edinburgh University, at the outbreak of the Crimean War Dr. Christison went out to minister to the wounded. After that he devoted himself to the study of scientific archaeology, of which he was one of the pioneers. In this sphere he found work once congenial and valuable, and in 1906 his University conferred upon him the honorary degree of LL.D. in recognition of his services. The fruits of his research were afterwards gathered by the Society of Antiquaries of Scotland, of which he was secretary for 16 years, from 1888 to 1904. He travelled over a great part of Scotland planning the prehistoric forts and minutely examining them, and the results of his investigations he contributed in many interesting papers to the Society of Antiquaries. About 10 years ago he was Rhind lecturer, and chose as the subject of his course "The Prehistoric Forts of Scotland." These lectures were published in book form. "Early Fortifications in Scotland" was another of his works.

FIRE PROTECTION AT HAMPTON COURT PALACE.

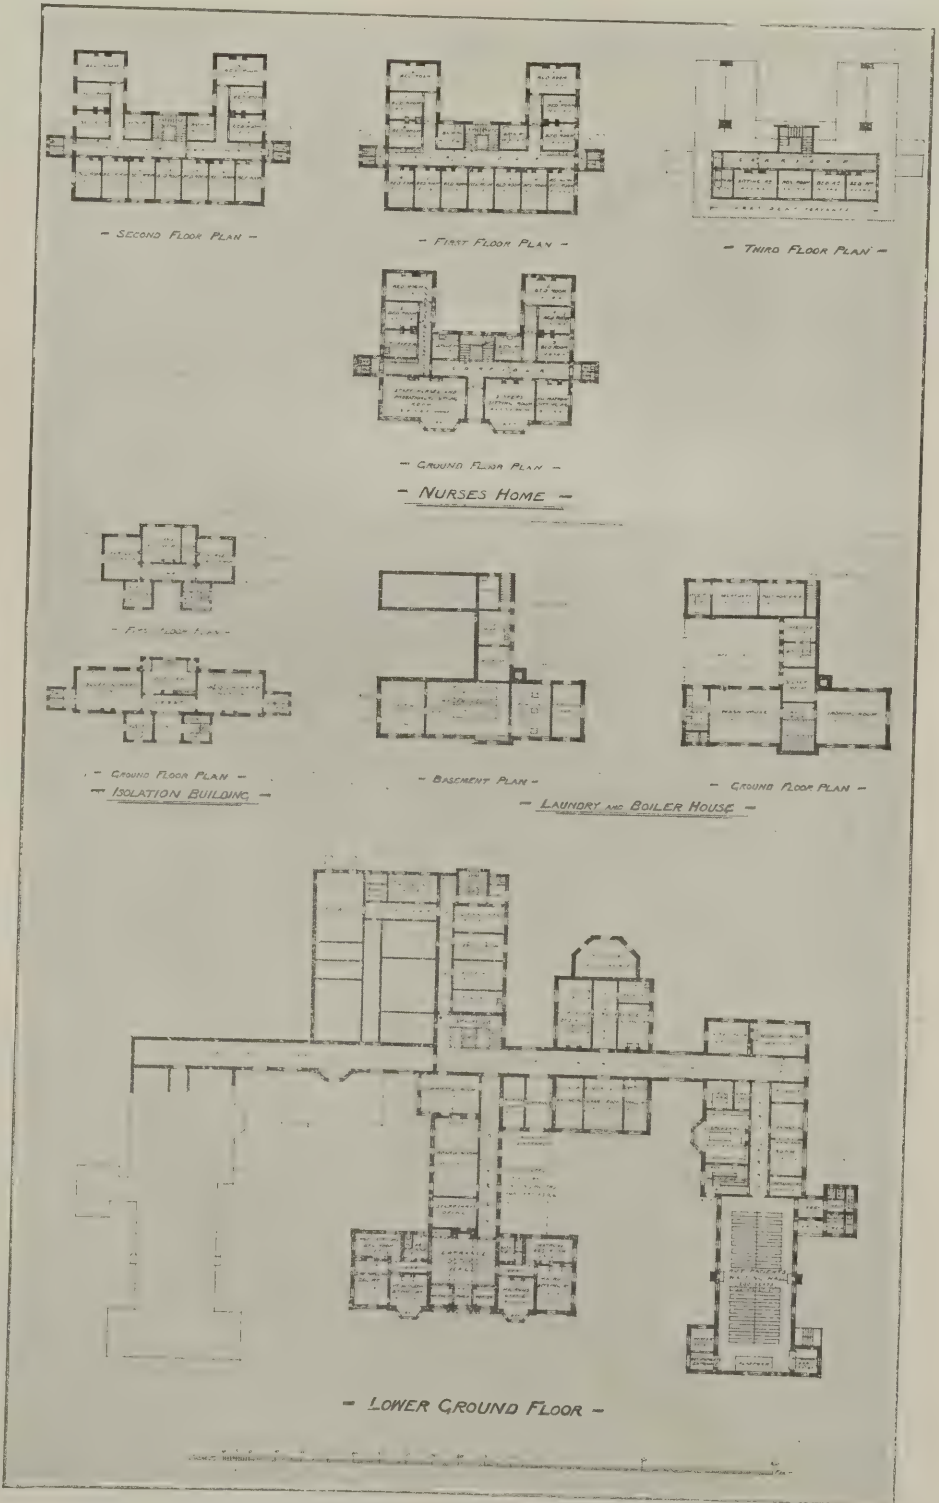

At the instance of the Office of Works, a scheme is now being carried out which will bring the protection of Hampton Court Palace from fire thoroughly up to date. The work of laying new water mains which are to furnish a high-pressure supply has been put in hand by the Metropolitan Water Board, who are carrying a 15 in. main from the Flower Pot in the Hampton Court Road right along the main walk in front of the Palace. In this large main there will radiate several 9 in. mains, while 4 in. distributing pipes will convey the water to all parts of the buildings. The pressure maintained in the pipes will suffice to carry water to the highest part of the Palace, and plugs and hydrants will be placed in convenient positions for immediate use.

A complete system of electric fire alarms will enable instant communication to be made with the Palace Fire Brigade, the members of which have the advantage of an intimate acquaintance with the buildings. The Palace has also been placed in direct telephonic communication with the Kingston Fire Station, where there are two powerful motor fire-engines which could reach the Palace within a few minutes of an outbreak. The Palace Brigade is being strengthened by the addition of three expert firemen who are ex-members of the Metropolitan Fire Brigade, and one of these men will always be on duty at the fire station in the precincts of the Palace. For their accommodation, three new cottages are to be built in the grounds adjoining the Palace.

NEW BOOKS.

Spirit Varnishes.

To those who are avid of hard facts, the modern facilities for tracing the origin of materials and the particulars of processes may be accounted an intellectual boon. For such persons—and their name is legion—there is a satisfaction of the mind in finding out, as nearly as may be, all that has been ascertained about the things with which one is specially interested. For example, the man who is constantly handling, or even only specifying, varnishes of one kind or another may, and often does, feel impelled to penetrate as deeply below the surface as he reasonably can, in order that he

THIRD-PREMIATED DESIGN FOR EAST SUSSEX HOSPITAL, HASTINGS. H. PERCY ADAMS, F.R.I.B.A., AND CHARLES HOLDEN, A.R.I.B.A., ARCHITECTS.

may be informed what the varnish is, whence it comes, its physical properties, its natural history, and the philosophy of its manufacture or preparation for use. The book under notice is extremely interesting, if only from this point of view, although it is doubtless more trenchant in its appeal to those whose keenness of enquiry is mainly commercial. A good deal of rather fascinating nature study, however, goes to the account in either case, whether we regard, for instance, the vegetable, mineral, or animal origin of the various products, or their chemical or other conversion to the final form in which they are applied. It happens that the natural history of spirit varnishes is exceptionally interesting. One of the most interesting chapters is that which deals with shellac, "the raw material *par excellence* of the spirit varnish maker." It is a secretion of the *Tacchardia lacca*, an insect allied to cochineal. Shellac consists of wax, colouring principle, and pure resin. The life-history of the insects is carefully narrated in the book, and is a very curious study, having in it certain elements of doubt and obscurity which render the subject by so much the more fascinating. That the resin is not an exudation of the tree, but a secretion of the insect itself, is a generally accepted opinion, but does not seem to have been finally established as a fact; nor is it beyond debate whether the different qualities of lac are due to varieties of the insect or to the different plants on which it feeds.

The chemistry and the methods of manufacture of the various kinds of varnish are described in considerable detail, and, as a rule, the names and dates of the various inventors and discoverers are conscientiously given. One interesting historical item corrects the common impression that benzol was "first discovered in its present grand source—coal-tar." Benzene was in fact discovered in 1825 by Faraday, who separated benzol by fractional distillation from the vapour produced by passing certain oils through red-hot tubes. The coal-tar process was elaborated by A. W. Hoffmann (1845), and, in Hoffmann's laboratory, by Mansfield in 1847.

Such particulars as those to which attention is here drawn are, however, merely subsidiary. The bulk of the book is occupied with purely practical matters. The amplified English version, like the French original, may, in fact, be regarded as a standard work—a veritable mine of information for the manufacturer, who will value it none the less because, unlike most technical treatises—at all events, unlike such as do not owe their inception to French authors, who have a happy knack of writing agreeably as well as clearly—it is really interesting to read, whether or not the reader has the intention of turning the information to direct practical account.

The Manufacture of Varnishes, and Kindred Industries. Based on and including the "Drying Oils and Varnishes" of Arc. Livache. By John Geddes McIntosh. Second, greatly enlarged edition, in three volumes. Vol. iii.: Spirit Varnishes and Spirit Varnish Materials. London: Scott, Greenwood and Sons, 8, Broadway, Ludgate Hill, E.C. Pages x. + 482, 8½ins. by 5½ins., 12s. 6d. net.

The Natural History of Clay.

Anyone harbouring the perfectly natural delusion that but little can be said about so seemingly simple a substance as clay will be surprised at the extent and variety of interest comprised in Mr. Alfred B. Searle's manual on its natural history. Clay, in truth, is by no means so simple as it seems to the layman, and

certain of its properties present problems which are as yet unsolved, chiefly because of "the inertness of the materials at ordinary temperatures, and the ease with which the clay molecule appears to break down into its constituent oxides at temperatures approaching red heat, or as soon as it begins to react with alkaline or basic materials." Nor is it easy either to define the true nature of plasticity or to secure its accurate measurement. These and other matters are discussed in a very interesting manner by Mr. Searle, who has produced a treatise in which much may be learned about every variety of clay, even by those who are most familiar with the uses to which it is put in the various fictile arts and manufactures, from the making of stock bricks to the production of the finest kaolin ware.

The Natural History of Clay. By Alfred B. Searle. Cambridge: At the University Press. Pages viii. + 176, 6½ins. by 5 ins.

Smoke Prevention.

The architect, of all men, has most reason to be keenly interested in the means of smoke abatement, not only when he is designing the buildings which create smoke, but even more especially when his aesthetic effects suffer a mere eclipse from it. The authors of "Smoke Prevention and Fuel Economy" believe "that coal of bituminous quality is capable of perfect combustion, and that black smoke is merely so much evidence of improper design and work," and in the book they present abundant reasons for the faith that is in them. Architects, whether they are doers or sufferers, or both, in the matter of imperfect combustion, will be glad to learn from this book all that seems to be certainly known on the subject.

Smoke Prevention and Fuel Economy (based on the German Work of E. Schmatolla). By Wm. H. Booth, M.Am.Soc.C.E., and John B. C. Kershaw, F.I.C. Second edition, revised and enlarged. With seventy-nine illustrations. London: Constable and Co., Ltd., 10, Orange Street, S.W. 232 pages, 8½ins. by 5½ins., price 6s. net.

Three Technical Manuals.

"Ship Wiring and Fitting," (a) by T. M. Johnson, is one of the excellent series of "Installation Manuals" that are being issued by Messrs. Constable, and is characterised by the same practicality and thoroughness of treatment as its forerunners. The special problems that present themselves in wiring a ship for lighting, telephoning, and ventilating by means of electric fans, are dealt with very lucidly and in complete detail.—A fourth edition of Mr. J. T. Cowderoy's "Pocket Notes and Remembrancer for Sanitary Inspectors and all engaged in Public Health Work" (b) is in effect a sufficient testimony to the utility of this well-arranged and very complete little manual, in which, we note, the "health-worker's interest in the Town-planning Act" is duly considered.—Mr. Horace M. Lewis has produced a small manual (c) on builders' quantities that will serve as an admirable introduction to the subject, giving the student a solid groundwork upon which to build a sound superstructure of further knowledge. The elementary operations of measuring areas, and of taking off the quantities for the various trades, are carefully explained, and examples of billing are added.

MODERN HOUSE PLANNING.*

BY A. G. R. MACKENZIE.

When I was asked to read a paper on the subject chosen ("That Modern House Planning tends to Over-elaboration") I consented to take the negative side, leaving the positive side to be brought out in the discussion.

Of all the characteristics of the modern house, the most striking when compared with the planning of former times is the multitude of purposes which it serves. Keeping pace with our more complicated ways of living, we have not only greatly increased the number of rooms, but have assigned to each a special purpose. Instead of the hall and single chamber of the Middle Ages, with which even kings were content, every ordinary house must have a number of separate bedrooms, at least three public rooms, and a complicated arrangement of servants' offices, with the development of civilisation we could not now live in those old palaces in which the only communication for a suite of rooms was by passing through each in succession.

I do not propose to trace the history of the house from prehistoric times, but merely to refer to the advent of prosperity in the times of Elizabeth, when the system of planning was revolutionised; and the house, which previously consisted of more or less detached buildings round a central courtyard, was made one by connecting all the parts together by means of corridors or galleries. It was to this period that Mr. Norman Shaw and his contemporaries reverted when forty years ago they awakened the architectural world to the realisation that modern houses *could* be planned with the spirit of the ancient work and with the comforts which modern conditions demand. It is to them also that to some extent the initiation of the recent movement of the planning of smaller houses may be traced—at any rate, they were the first to realise the possibilities of the good architectural treatment of the smaller suburban house, which, now that garden cities have come into existence, has become so interesting a subject to the man in the street and his wife as well as the architect. We are now considering whether over-elaboration is a demerit or simplicity a merit, whether the present tendency is to over-elaboration—and I contend it is not regard elaborate planning as not necessarily leading to elaborate results. It is to say, that a house which looks simplest in the world may, to attain that simplicity of effect, have caused more elaborate planning on the part of the architect. An elaborate house is the same thing as an elaborately planned house: the one conveys the idea of complication, the other simplicity in considered result.

Although an elaborately planned house does not always bring simplicity, a house that is planned without due elaboration or consideration of detail certainly only bring simplicity of effect by sacrifice of comfort. Bacon says so where in one of his essays: "Houses made to live in, not to look upon." The ideal house is, first, one which is comfortable to live in, and, secondly, fair to look upon. The one follows the other.

Of the works of man that approach more nearly to nature in their perfect

* Extracts from a paper read before the Architectural Association on January 29th.

one may instance sailing ships; these have not been designed to look beautiful, but have become so by the process of elaboration and elimination which has continued through centuries till this ideal has been reached. And so it is with house buildings. The planning is the key to the situation, and it is by elaboration and elimination of everything that has not a *raison d'être* (for elaboration includes elimination) that the perfect house is attained. That there are numerous examples of over-elaboration is true, but that some have fallen into traps ambushed by the wayside does not affect the general forward movement.

When Professor Reilly, at the Architectural Congress, made his plea for a more classical treatment of the Garden City, I confess I was captivated by the plea, and saw in my mind's eye relief from continual picturesque bits and fussy detail (it is curious how pleased one is with one's own happy thoughts in picturesque features, and how impatient one is with other people's). I was captivated by the idea of a Georgian Garden City designed with due regard to axiality and symmetry. That great dignity can be obtained by axial planning goes without saying; the architects of the Georgian period knew this, and those who allow them now recognise the value of the vista and balance. How far this can be carried, however, in the smaller house, is to my mind a very debatable question.

An elaborately planned house is to my mind one in which everything is considered so that there is no waste of material, and useless space is reduced to a minimum. This is particularly true of smaller houses. Indeed, the smaller the house the more elaborate should be its planning.

As an illustration, I would take the question of cupboards. In small houses inhabited by people of moderate means, it is much more necessary to fit in cupboards to every possible nook or corner than it is in larger houses where space is so valuable, because in the former case not only is every inch of space required, but the cost of purchasing furniture, such as wardrobes, becomes a consideration. In the larger houses the elaboration of planning would probably consist in the fittings suiting the decoration.

Garden cities have led to the study by architects of small houses, and the elaboration of planning which has followed has all been to the good. If one compares the best, or even the average houses designed by architects at the recent exhibition at Gidea Park, with the builders' erections ten or fifteen years ago, it is ludicrous to maintain that there is any tendency except towards improvement.

Two houses in Gidea Park [of which designs were shown by the lecturer] are an excellent illustration of my contention that elaboration leads to apparent simplicity, and showing how misleading it is to talk about a simple little house as the simplicity was attained by obvious methods. They show how, by an elaborate arrangement of chimneys and clever distribution of the rooms, a very simple external effect is obtained, while the heat is conserved for the benefit of the room.

How much more simple to plan a house with all the chimneys in the walls, how much less pleasing is the result! Although the author of the Gidea Park example has described it as "planned in the simplest possible manner," prob-

ably it would have been more accurate to have said "planned with much thought and elaboration, eventually arriving at a simple result."

In the larger houses of to-day the same principles of planning are being applied, though the object of the elaboration may not necessarily be directed so much to questions of economy, towards obtaining the most efficient result with the minimum of space and expense, as to additional luxury and obtaining a fine architectural building with the maximum of luxury and convenience for the owners.

We must take our clients as we find them; and the question which architects have to solve is not how a rich country squire can so modify his requirements that a quiet, dignified, and beautiful house can be built for him, as how to build him a house and still give him all the conveniences and luxuriousness he desires. By the facilities for intercommunication now available, among other reasons, life in country houses has become much more complex than it was in the past. Huge house parties can easily be gathered together, and their successful entertainment greatly depends on the provisions made by the architect, more particularly perhaps in the servants' quarters. Ladies now take a much greater part in life generally, and their not being banished to their withdrawing rooms has led to the development of the hall, where they and the men can meet, and both can come

and go without formality. That this apartment has to be a sitting-room, sheltered from draughts, and yet still the hall of the house, has led to much ingenuity in planning.

The necessity for bathrooms and suites of rooms which may or may not be used in connection with each other also leads to further complications. [This was illustrated by an American plan.]

The desire for unlimited fresh air is a consideration which is daily becoming more urgent. No one now sleeps with his or her window shut, and the fresh-air habit, like any other, tends to grow. To a person who habitually sleeps with both windows and door wide open, it is perfect torture to be closed up, and to waken in the morning with the feeling of oppression that want of fresh air gives; it is all a matter of habit, and this habit is on the increase. Very soon the desire for open windows will lead, as it already has done in America, to the provision of sleeping balconies attached to the bedrooms, surrounded by a dwarf wall and open on two or more sides, so that by means of shutters the side sheltered from the wind that may be blowing can be left open, and the others closed. The American plan shows one example of this, and also a sun parlour, which I take it can be used for meals in hot weather. Some American plans show loggias facing east and west available for this purpose, whichever quarter the sun

SLEEPING PORCH TO HOUSE AT EVANSTON, ILLINOIS, U.S.A.
W. A. OTIS AND EDWIN H. CLARK, ARCHITECTS.

is in, and the balconies over are ready to be converted into sleeping balconies, with the addition of roof and shutters. I feel now there is a great future for the open-air room, not merely a veranda, but wide enough, at least 10 ft., to have dinner served in. I anticipate that when these have been provided the next demand will be for places where one can take an air or sun bath.

But, to conclude, there can be no doubt that the subject of domestic architecture is one which interests us as English architects more nearly than any other; if one looks for fine general planning and magnificent public buildings designed on a scale to impress the mind with the greatness of the nation, one is disappointed. It is in domestic architecture that England excels, and I claim that it is by continual study and elaboration of planning that this reputation has been built up, and it is by that alone that it can be maintained in the future.

DISCUSSION.

Mr. G. H. Jenkins said that evidently Mr. Mackenzie had defined "elaboration" as the process of improving and refining by successive operations. They would therefore all agree that modern house planning did *not* tend to over-elaboration. He was of the opinion that modern house planning generally tended to over-elaboration on the wrong lines. Mr. Jenkins said he would like to contradict

the heresy which was being constantly preached by certain of the younger school of architects, that beauty was not a thing to be sought for its own sake, but was only a side issue—a something which could not be attained by effort.

Mr. Mackenzie stated that the ideal house was, first, one that was comfortable to live in, and, secondly, fair to look upon. A house, said the speaker, could not be comfortable if it was not fair to look upon, as, if everything was displeasing to the eye, peace of mind would not accompany ease of body. The modern house, he thought, was sufficiently elaborated to ensure its being beautiful as well as convenient. Beauty, however, was only a secondary consideration instead of being of equal importance with convenience in producing the ideal home. If we did not realize this, we should tend to fall behind times.

Modern house planning, he thought, tended more to the multiplication of unnecessary conveniences than to the elimination of needless features, both inside and out. Because it was more difficult to eliminate than to do the reverse, and because we saw it practiced so rarely, a doubt was thrown upon the success of such a course. Mr. George Lucas had been bold enough to dare to eliminate, and he left it to the meeting to judge whether fine results might not be obtained by this means.

Mr. H. V. Ashley said he had listened to the paper with interest, but was in total disagreement with the lecturer. He found that the word "elaborate" had a positive and certain meaning. Murray's Dictionary gave the definition of the word as follows:—"to produce or develop by application of labour; to fashion a product of art or industry from the raw material; to work out in detail; to give finish or completeness." He laid stress on this definition because from a certain amount of study of modern houses it became evident to him that house planning was seldom elaborate, and never over-elaborate. He thought that the houses of the seventeenth and eighteenth centuries were probably more elaborately planned than was the case; they were built—the latter houses, at any rate—with fine laid-out dignified suite and reception rooms, noble approaches, and even at the period we find that the architects fought again and again to work out in detail or to elaborate the upper and lower floors, etc. Again, in the work of the early part of the last century we find the reception suites elaborately

HOUSE AT EVANSTON, ILLINOIS, U.S.A.

particularly in town houses; but in the bedrooms, kitchen, and servants' accommodation, we have a hopeless muddle of badly placed rooms which result from failure to work out in detail or elaboration. As to modern house planning, it had been elaborated, but over-elaboration seemed to mean incompetence, and to suggest to architects that the limit had been reached. To plan perfectly a modern house, either large or small, demanded a great deal of application and labour and working out in detail, all of which meant elaboration. How many modern plans of houses could be said to be perfect in, say, only the following points: Lay-out on site and treatment of levels; aspect—sunlight in rooms, etc.; convenient and dignified entrances, halls, and reception rooms; convenient services from kitchen and pantry, and so to dining-room; right position of doors, windows, and fireplaces in rooms; proper and economical planning of sanitary arrangements, baths, lavatory, sinks, etc., and their waste supplies; in obtaining a proper note of distinction over the whole house, and reflecting on clients' wishes and the architect's ability to grapple with them and to elaborate the house; or, as the definition had it, to fashion a product of art from the raw material?

Mr. H. H. Wigglesworth said that the practicability of a plan was of course essential; and if an architect had a sense of beauty he was bound to express it with his practical ideas.

Mr. Geoffrey Lucas, having dwelt on the historical development of house plans, spoke of modern times, when it was required that no rooms should open one to another and that corridors should be provided for each room. Though a plan were elaborate, it might also be simple. The drawings of Phil May were very simple; but he drew and re-drew and eliminated until only the actual essentials remained. It should be the same with the architect. The problem at Gidea Park was partly to do something simple and partly not to do anything picturesque. To do a simple thing with an eye on proportion was exceedingly difficult; and a balanced design, on a small scale, was much more difficult than a picturesque one. When a thing was brought down to a small compass the difficulties became apparent—as an instance, having to make a w.c. window balance with a hall window. In the balanced design, proportion and form were much more important than in the picturesque gabled type of building. If we are to progress in domestic design, said Mr. Lucas, it must be with culture and with a certain amount of cruelty to ourselves, in the way of forsaking certain favourite affectations. It was very difficult to cast them off when one got to like them; but one asked oneself: "What did they lead to?" No one could go to the Guildhall at King's Lynn, for instance, as the ideal guide to the design of a modern town hall for a country town. It was crude and incomplete, though a fine piece of work. The same principle should be observed in the design of a house. Having got the plan, let it make its own elevation. He thought that this idea that a style of domestic architecture could not be produced without harking back to old forms and conditions was out of sympathy with modern society.

Mr. T. L. Dale said that at Gidea Park and similar places architects elaborated it to produce a better house, but a

cheaper house; and the only persons who benefited were the enterprising gentlemen who develop garden suburbs. By making a house cheaper the ground landlords were able to charge more in ground rents.

Mr. A. E. Bullock drew attention to the importance of windows in house design. If sash windows were required, then the design would be Georgian; but if casement windows, then Elizabethan.

Mr. C. G. Boutcher, referring to Phil May, said that in May's case there was elaboration because of the amount of thought put into his work.

Mr. P. M. Fraser said that one of his ideals had been shattered if the remarks about Phil May's method of drawing were correct. He always had understood that May did his drawings in a few seconds.

Mr. W. Curtis Greene said that if we went back to the time when small houses were beautiful things, analysis would reveal their inherent simplicity. A simple instinct of good craftsmanship seemed to pervade them. The old craftsmen did not design their houses—they built them; and they produced what we now say are admirable pieces of building. Coming to the modern practice in domestic design the speaker said that cupboards were largely employed to fill up inconvenient corners; and although ingle-nooks were well enough in old farm-houses with smoke-stained walls and cavernous chimneys, to introduce them without any relevancy, as was so frequently done at the present time, seemed to be a pernicious practice. To the architect who was pleased with some particular piece of design he would say, "Rub it out." This was a good working principle.

Mr. Gerald Horsley said that apart from the difficulty of producing a fine, dignified plan—simple, well-arranged, and suitable for its purpose—there were many smaller difficulties to be considered nowadays. For instance, the necessity for providing a large number of bathrooms. A few years ago one was sufficient for a moderate sized house; then two became necessary; and now it was not uncommon to have to provide several suites of rooms composed of bedroom, dressing-room, and bath-room. This, of course, was not difficult; but the necessity for additional down pipes and ventilating pipes was something of a problem. These pipes never improved the appearance of a house when put up; and he wondered whether any satisfactory

method of disposing of them had been devised.

Mr. Mackenzie, in reply, said it was only by dissatisfaction and constant striving that they could hope to make progress. Turning to Mr. Horsley's question, the speaker said the Americans concealed their pipes, this being practicable in their climate. He thought that, with modern sanitation, it could be done to a certain extent in this country.

Mr. G. H. Jenkins corroborated this statement, and described a method of concealing unsightly pipes by means of a chase in the wall.

A sleeping porch at the recently completed Evanston residence of Mr. W. S. Mason is illustrated at pp. 173, 174 from drawings and photographs kindly lent by Mr. A. G. R. Mackenzie (of Messrs. Marshall Mackenzie and Son), to whom they were sent by Messrs. William A. Otis and Edwin Clark, architects, of Chicago.

This porch, it will be seen, is directly connected by French windows with the daughter's room, as also with the governess's room, and has space for two beds. The openings between the columns of the porch are filled in summer with copper-wire screens of fine mesh, so as to prevent annoyance from flies or insects. In the winter, curtains, as shown, afford protection in very extreme weather and driving storms. Some owners arrange to substitute glazed sash for some or all of the screens in winter, but apparently it then loses the main object desired—namely, that of permitting the occupant to sleep in the open air.

A plan is also given of a fine sleeping porch in a house at Glencoe, Illinois, recently built from Messrs. Otis and Clark's designs. The same general scheme is adopted here, with such modifications as were rendered necessary by the house plan, the points of compass, etc.

It happens that both these examples are associated with houses designed in what is known as the Colonial style. Such porches, however, are becoming more and more frequent upon almost every type of house in America, whether of stone, brick, wood, or plaster.

These porches, as shown in the illustrations, are most frequently built over a first-storey porch, and the floors consequently have to be water-tight in order to form a roof for that porch, and various expedients are employed with that object. Usually in good work a regular "tin" roof is erected, and upon this open slat work is laid.

PRECAUTIONS AGAINST FIRE.*

By A. J. STUBBS, M.Inst.C.E.

THE first point of importance that attracts one's notice as soon as the subject of fire prevention comes under consideration is the fact that destruction by fire is such absolute waste, without the least or most remote compensatory influence. In the British Isles alone the annual destruction of property is estimated at something approaching seventy million pounds sterling. The fact that a very large proportion of this is covered by insurance does not reduce the seriousness of the losses—the community is poorer whether the merchant, trader, and small householder, or the rich corporation, should happen to pay the bill. National wealth to that amount has been reduced to ashes.

Loss of Life and Property.

But an even more serious matter is the loss of life that goes hand in hand with this destruction of property. The losses under this head include not only the lives of the unfortunate occupants of the destroyed buildings, but also those of the gallant fellows who go to their rescue or perish in attempts to stop the spread of the fires.

A yet further consideration is that incalculable loss is engendered consequent on the stoppage of business and the resulting loss of work for all classes of citizens.

In a thoughtful and able paper read before the Surveyors' Institute in 1898, Mr. Thos. Blashill, the then Superintending Architect of the London County Council, said: "It is a question whether danger from fire is not increasing in spite of Building Acts. Our buildings are getting more lofty, more closely packed together, and more thickly inhabited. In commercial buildings the rooms are larger and more encumbered with goods in and over which manufacturing processes are carried on. There is more machinery actuated by heat. The timber we use is more easily combustible, fittings are lighter, and everything is kept warmer and drier. All our arrangements for obtaining light, from the lucifer match to gas and mineral oil and electricity, are novel and productive of new dangers. The proportion of window openings to wall space is much increased, and, with the growth of honesty outside, or trustfulness within, shutters have been abandoned. . . . Lifts going through several storeys neutralise the advantage of fire-resisting floors, lighting areas common to different premises do away with the security of the party wall. . . . In fact, the most scrupulously legal building of brick or stone and slate may be no more than a kind of grate in which its internal structure and its contents can be most conveniently burned. So in the Cripple-gate fire the progress was about as rapid as, and the destruction over its limited area no less complete than, in the Great Fire of 1666, and if our arrangements for the extinction of fire had not made immense progress this recent event might have rivalled that great calamity."

Sources of Risk.

Some of the risks due to construction, planning, and uses of buildings may usefully be mentioned, even if they be practically irremediable.

Windows overlooking narrow streets or areas are an ever present source of risk. The destruction last year of a telephone exchange in the North was due to the spread of a fire from an adjacent building on the other side of a narrow lane. No doubt spread of fires from this cause would often be retarded or even prevented if reinforced glass were used, provided that it were fitted in iron frames; and fire-resisting shutters might be depended upon to keep out fire for a considerable time. Of course, in all such matters the *existence* of the device is only the first point; the value lies in its being in order, and being actually used as a regular practice.

There are many post office buildings with wood staircases. Do you know of any where there is a very convenient cupboard beneath? Suspect that cupboard! It is nearly sure to contain combustibles which some evening will be inspected by means of a lighted match—and the means of exit for the night staff above will be a suffocating chamber of smoke or a blazing gap.

Bad construction of flues, stoves, etc., is perhaps not a source of danger in many of our buildings, but it is worth while to realise that there are such possibilities.

Non-existence of a lightning conductor, or position or procedure which jeopardises its continuity, would naturally attract the attention of an electrical engineer.

I think that the use of a heating chamber as a wood store should be deprecated. I have observed such a combination!

Means of Escape.

Again, where the Office of Works provides special facilities for escape in case of emergency, the construction is probably satisfactory, but such facilities must be kept usable. When travelling, I always make a point of knowing what the hotel fire-escape arrangements are, and a few months ago my inspection of the place to which the "fire escape" notice pointed, revealed a small landing packed with chairs, a table, and three or four hip and sponge baths—only just put there, the apologetic representative of the manager told me, because the hotel was so full! Loss of life is probably far greater as a result of panic than from fire itself, and gangways and means of egress must be *always* considered sacrosanct if the safety of life is at stake. This was the great lesson of the terrible Ashe Building fire in New York. There the fact that a "skyscraper" was involved was of little moment; the structural damage was so slight that even the fire itself was not a great factor, but the actual loss of life reached a total of 145, and there was a heavy roll of those seriously injured. Why? Because exit-doors opened inwards; because there was no clear prearranged system of using the very considerable fire-extinguishing facilities, and no instruction of the employees as to their procedure in such an emergency.

The height of the building made a difference for some of the 40 victims who, for want of other exit, jumped from the windows; but it was immaterial to 95 who never got out of the eighth-floor room in which they were working—some overcome by smoke before they got

clear of their branch gangway. Panic and want of gangway killed more than the fire.

Hydrants, etc.

Most of our larger buildings are equipped with hydrants and hose. A point in this connection that is well worthy of attention is to have the hose coupling interchangeable with those of the local fire brigade. I am rather inclined to favour permanent coupling of the hose to the hydrant. An obvious objection to this is that in case of the valve being leaky, the hose may be deteriorated, but this may be obviated by having a small tap kept partly open on the outer side of the valve. Then, if leakage occurs, water will drain from the tap and direct attention to the fault. Generally, there is also a tap on the hydrant from which the water buckets can be replenished.

At the General Post Office.

It may be worth while briefly to describe the rather exceptional hydrant system at the General Post Office, London. Here the north, west, and east buildings are encircled by a 6-in. ring main. Hitherto this main has been fed by steam pumps, but in connection with the development of the power station scheme, these will be replaced by electrically driven pumps, now being installed at the G.P.O. West. The supply of water is obtained from two entirely separate service mains.

The new plant will consist of an electrically driven centrifugal fire service pump, capable of discharging 270 gallons of water per minute against a pressure of 100 lb. per square inch. An electrically controlled hydraulic accumulator will be arranged to start the pump when the pressure falls below 100 lb., and stop it when that pressure is restored.

As a stand-by the two new domestic service pumps will be so arranged that they may be connected in series and arranged to discharge into the 6-in. main by the operation of a single series parallel valve.

In the event of both pumps being imperative, the supply of water stored in the tanks on the roof of the G.P.O. North can be drawn upon by aid of an automatic non-return valve, which will be fitted between the fire main and the main from the domestic service pumps to the tanks.

The hydrants throughout the buildings are served from the ring main.

Automatic Extinguishers.

An interesting resume of the history of automatic sprinklers was given in a paper by Edward V. French, presented before the Congress of Technology, at Massachusetts. He says that the idea originated in England about 1850, and at first consisted of lines of pipes drilled with small holes; the service being by separate mains for each floor, and all the mains being controlled by valves outside the building. I remember those sprinklers and the gibes of the thoughtless that they had to bear. But their possibilities were also early appreciated. Much good work was done in developing the idea, and 1875 saw the first automatic sprinkler.

"The great points of advantage which the automatic sprinklers possess over all other means of fire-fighting are that they are on duty every hour of the day, and every day in the year; the heads which are open are those located just where the fire is; the open heads ca-

*Extracts from a paper read at the Metropolitan Centre of the Institution of Post Office Electrical Engineers, January 8th.

operate regardless of smoke or other conditions which would make it difficult for men to reach the seat of the fire. Such protection can cover every nook and corner of a plant and insure that fire starting at any point will be almost instantly met with such a downpour of water as either to extinguish it entirely, or hold it in check within a small area until the last vestige is extinguished by the fire brigade."

It is evident that the requirements are very exacting. The device, fitted near the ceiling and subject to very considerable variations of temperature and of atmospheric conditions, must so effectually resist corrosion and any other deteriorating influences that it will not be in the least likely to open when there is no fire; but will yet remain so sensitive that after years in readiness unused it will respond to the agreed degree of temperature within a period of from 30 to 50 seconds as readily as it would on the day of its first installation.

The ordinary arrangement of the automatic sprinkler head is to have a half-inch diameter orifice normally closed by a valve held in position by an arrangement of levers or links which are held together by a soft solder, melting at a temperature of, say, 160° Fahr. Such a sprinkler will protect an area of 80 to 100 square feet.

The development of the use of sprinklers has been wonderful. They have proved themselves capable not only of extinguishing fire in protected buildings, but of preventing the entry of fire from adjacent buildings, and Mr. French instances a case of a great fire which destroyed a considerable city block and threatened two adjacent protected factories. In one of these the exposure was so severe that the wooden frames and sashes of the exposed windows were burnt out, and the resulting operation of the sprinklers constituted a prime factor in preventing the total destruction of the building, which was actually comparatively slightly damaged by water.

The only consideration of any moment in connection with an outbreak of fire, if there exist any possibilities of extinguishing it, is *time*. Existence of facilities for dealing with a *small* outbreak of fire, and presence on the spot of means of using those facilities *at once*, would almost abolish need for the wonderful fire-combating system that is such a source of pride and satisfaction to every up-to-date community.

In a very able and interesting paper prepared by Mr. Oatway some years ago he stated that on analysis of the 716 fires dealt with by the Glasgow Fire Brigade in 1902, and estimated to represent a loss of £189,000, ten fires accounted for 73 per cent. of the loss. Thus, given such conditions of prompt attack for those ten fires, as had been possible on the average of the other 706, the total loss would have been reduced by over 70 per cent.

Similarly the London County Council experience is that the proportion of serious fires to the total reported is only 2 or 3 per cent. It will not be overlooked in this connection that hundreds of outbreaks never reported at all, because taken at the earliest stage, contain the same possibilities of disaster as many a great burn-out, save only in this prime consideration of *time*.

At first sight one might be inclined to question whether there is room for both automatic sprinklers and automatic alarms. If you can depend upon

sprinklers to put out the fire, why call the brigade? But a little consideration would show that neither system is so perfect as to exclude the other. One of the most characteristic differences in the conditions of operation of automatic sprinklers as compared with present-day automatic alarms is that the latter are "compensated"—that is, the only systems that count provide for operation of the alarm on a sudden rise of temperature to an agreed amount, whereas sprinklers depend for their operation upon the rise of the temperature to a specified thermometer reading. The importance of this, especially in a climate where the range of temperature is very great, is obvious. For example, the operating point of a sprinkler in a room must obviously be fixed safely above the maximum temperature to which the air at ceiling level can possibly be raised in any normal conditions. The temperature usually adopted is 160° Fahr. It is clear, therefore, that the promptness with which a sprinkler will be brought into operation in the winter will compare very unfavourably with its response in the same room in the height of summer, as in either case the temperature of the whole room must be so raised that the ceiling temperature is 160° Fahr. On the other hand, the compensated alarm device is so arranged that, no matter what the normal temperature may be, a *sudden* rise of, say, 25° Fahr. will operate the alarm. At the same time, it is important that alarm shall be given when a dangerous heat is being generated quite slowly by a smouldering fire. This can readily be provided for.

[The author then described the May-Oatway, the Pearson, and the Aero alarms.]

Minor Appliances for First Aid.

We have now to turn our attention to a few "first-aid" appliances.

(a) *Water Buckets.*—The author held very definitely that these should not be placed in switchrooms, test-rooms, etc., where swamping of wires on slight necessity might have very disastrous results in regard to breakdown of circuits by water. Their sphere is in corridors, offices, linemen's rooms, etc. Wherever it is proper that they be installed it is also proper that they be placed in accessible positions and that they be charged with water. Some time ago, I noticed some fine-looking buckets marked "Fire" hanging over the doors of some rooms—a peculiarly handy position in an emergency!—but the occupants of the room had not observed their existence, and it is probable that they had been strangers to water since they were placed in position. In that building, too, I fancy that taps over lavatory basins present the only source of water supply nearer than the basement.

(b) *Sand Buckets.*—In dealing with fire we need to recognise that force of impact of the extinguishing matter is always a very important factor in its effectiveness. This is particularly the case with sand. Probably a few handfuls correctly thrown will be more effectual than a whole bucketful poured out, because it can rarely happen that the sand will stay where it is wanted. This consideration has no doubt been the reason for the adoption in some cases of large sand buckets provided with scoops or cups; but on the whole I am inclined to think that the engineering department representation on this point is best—the use of small buckets, the weight, including sand, not to exceed

16 lb. Such a bucket gives a fair chance of effective use if it be necessary to work against an inaccessible point, and at the same time is equally convenient for use of the sand by handfuls. It is better to have a group of, say, four small buckets than a smaller number of large ones—especially since under excitement the first shot is likely to be a miss! Mr. Harold Sumner, in a very able paper on protection of factories, recommends that the sand be slightly moist. The idea appeals to me, but I am not clear how it would be practicable to keep the sand in that condition.

(c) *Asbestos Cloths.*—I have never been able to picture any possible effective use in an exchange building for a large asbestos sheet. I can picture one acting as a draught-producer by partial enclosure of a blaze, or conceivably as a fire-screen, but never as a fire-fighter. We issue no specific instructions on the use of asbestos cloths, but personally I think always of a small cloth (say, 3 ft. square, as a maximum) wrapped round one's arm and hand, serving as a device for punching out an incipient fire; or, possibly (where there is no risk of spreading burn-material) the cloth might be useful for beating out a smouldering fire.

(d) *Powder Extinguishers.*—The idea of chemical extinguisher—whether powder or liquid—is the production at the seat of the fire of an anti-combustion gas. The general composition of the various powder extinguishers on the market is, of course, a trade secret; but the following analysis sufficiently closely indicates the character of the materials:—

	Parts
Sodium Bicarbonate (with a little Sodium Carbonate and common Salt)	52
Aluminium and Magnesium Silicate	32
Chalk	8
Water (free and combined)	8
	100

The fire-killing property of those powders is unquestionable, providing that they can be applied to be in efficient contact with the heat.

(e) *Liquid Extinguishers.*—These are really small self-acting fire-engines, having a fixed capacity and a pressure which ranges between 90 and 150 lb. per square inch. They consist essentially of containers (of steel or copper) filled with water and bicarbonate of soda, the extinguishing power of which is many times (say 10 to 12 times) greater than that of water. The device is brought into operation by the automatic liberation of acid into the solution. The resulting gas gives the necessary pressure to expel the solution. The great advantages of these chemical fire engines, from the engineering department standpoint, are that (i) as compared with hand fire engines they can be worked single-handed; (ii) the efficiency of the liquid may enable the extinction of a fire to be effected with much less damage to electrical plant; (iii) in addition, as compared with the more ordinary "first-aid" devices (water buckets or sand buckets), it is dirigible, so that every pint tells; and (iv) the liquid is applied under considerable pressure.

(f) *Hand Fire Engines.*—No doubt hand fire engines have a sphere of usefulness, but I must admit that they do not appear to me to be a very valuable first-aid appliances for ordinary conditions in post-offices. I fancy that

most men not specially instructed (which is the case with most men) would like to have a minute or two with the engine before starting to use it against a real fire. It seems quite likely also that if a man, after discovering a fire, has to go to seek another to help him work the engine, and together they find out *how*, by that time one of them had better go and call the brigade while his mate watches the engine and the fire!

FIRE PREVENTION NOTES.

First-aid Fire Prevention. The human tendency to neglect what is obvious applies rather markedly to fire protection. This fact was the text for much practical comment by Mr A. J. Stubbs, M.Inst.C.E., in his lecture on "Precautions Against Fire," read at the Metropolitan centre of the Institution of Post Office Electrical Engineers. He points out that it is necessary to say; after spending time and thought in the production of a fire-fighting system, "keep it in order." It is foolish, as he says, to make elaborate preparations for fire, and then to have them all nullified by an empty bucket, or a wrong hose coupling, or a missing coupling key. Even more heart-breaking was an experience, some few years ago, at a great public school. The school was well equipped with first-aid appliances, and boys and men-servants were thoroughly well drilled in their use. A fire broke out, the amateur fire brigade was rapidly assembled, each person taking his appointed position and performing his allotted task with splendid celerity. Everything went without a hitch until the moment came for turning on the water. It was then found that in order to do this it was necessary to send a considerable distance to the dwelling of the turncock. He had to be dragged out of his bed; and by the time he arrived on the scene the public fire brigade was doing its best to suppress what had become a very serious fire. The dependence on the public turncock is inexplicable, and was disastrous.

Inspection Essential. Of course, as Mr. Stubbs said, and as we have so often pointed out, regular and systematic inspection is absolutely essential. "A weekly inspection is not too much, and a monthly inspection is, in my opinion, the outside limit. The inspecting officer should take an exacting view of his responsibility, and should recognise that weak points in the system itself come within his province for report. Besides seeing that the appliances generally are in order—buckets charged, asbestos sheets in position and easily removable, hose-coupling keys correct, taps and cocks turnable, etc., etc.—he should report any doubtful or irregular conditions; as, for example: (1) inflammable materials placed in dangerous or risky positions; (2) existence of unprotected gas-burners that should be fitted with wire globes; (3) blocking corridors, or other escape facilities, by cupboards, etc.; (4) employment of temporary stoves, or temporary placing of carpenters' bench near a stove; (5) removal or non-existence of desirable notices."

Testing the Appliances. It is easy to agree with Mr. Stubbs that this frequent inspection should be supplemented by regular periodical tests of

personnel and of appliances, and that the tests should be thorough. "Anything that can only be made 'to work near enough' under test will infallibly *not* work in emergency. It may be a very simple matter when testing, 'to get the hydrant key from the next floor,' but on the one occasion when it is really wanted this may be impossible. Every item should be *known* to be right, every operation that would be needed in case of fire should be actually and easily done." There is much practical wisdom also in the advice that the inspection and tests should not always be made by the same man, whose familiarity with the conditions may dull his sense of their defects. The element of competition will make for keenness; the inspector being all the more alert for the knowledge that he is himself, in a manner, under inspection. In this way perfunctoriness will give place to punctiliousness: both of which are evils, perhaps, but the latter being infinitely preferable in a matter in which, while fussy fastidiousness may be merely annoying, laxity may entail consequences that are absolutely disastrous.

Fire Brigade Competitions.

That keenness is engendered by competition we have noted some striking examples. Large private firms appear to be aware of its important influence on "smartness" in their brigades. Different departments are pitted against each other, and prizes are awarded to those that show most efficiency, whether as individuals or as brigades; and there can be no question of the value of this form of stimulus in getting the men to extend themselves. A short time ago we happened to be present at a London railway terminus on a Sunday afternoon, when there was but little traffic running, and when the station yard was clear and most of the men were off duty. A contingent had been got together for fire drill; and the officers in charge informed us that, in view of a forthcoming competition, the men not only cheerfully gave up their Sunday afternoon rest, but, as the result of frequent practice, coupled with the desire to distinguish themselves in the contest of brigades, they had shown an almost incredible improvement in speed and efficiency. The officer was timing their operations with a stopwatch, and recording their progress.

Dry Drill and Wet Drill.

This was, it need hardly be said, a "dry" practice, as is, necessarily, most of the drill of private brigades. There is a natural desire to avoid the inconvenience and possible damage that are inseparable from the actual use of water in practice. We know of one or two large firms, however, who occasionally allow their brigades to play upon the premises, and to behave exactly as if a fire had broken out; the point of origin being assumed and indicated, and operations directed accordingly, the men using ladders, climbing over roofs, and negotiating difficult approaches just as they would in the case of a fire. These realistic practices occur either before the premises are opened for business, or after they are closed; and to compare them with the ordinary "dry" drill is to emphasise an enormous disparity. The wet drill, as a business manager informed the writer, is "well worth the mess and fuss," while the damage done by the water is quite insignificant, and is more than counterbalanced by the cleansing that occurs.

STORAGE OF PETROLEUM SPIRIT

A useful indication of approved precautions against combustion where petroleum spirit is stored is afforded in the following recommendation by a Committee of the London County Council:

That a licence be granted to the Anglo-American Oil Co., Ltd., for a period of 12 months, as from the date of the completion of arrangements satisfactory to the Council, to keep 100,000 gallons of petroleum spirit at the company's premises, Tea Rose Wharf, Rainville Road, Fulham, subject to the surrender of the firm's current licence for the storage of 43,000 gallons of petroleum spirit, to the following conditions, and any other special conditions applicable to the case and necessary to secure safety, and to the usual conditions attached to licences of this character granted by the Council—

(i.) That the spirit be stored in seven tanks, each of 12,000 gallons capacity, in the positions shown on the plans, and in strong, securely closed metal vessels—namely, steel barrels, 5-gallon drums and 2-gallon cans in the filling-house and store-room, provided that the quantity to be stored in such vessels does not exceed 16,000 gallons.

(ii.) That the five new tanks and all piping connected therewith be constructed of the best material; that these tanks be sunk underground in a substantially constructed brick and concrete chamber as shown on the plans, such chamber to be not larger than is necessary for the reception of the tanks, allowing a space between each of not less than 12 in.; and that all spaces in the chamber not occupied by the tanks be filled with sand.

(iii.) That all manhole covers and points at which pipes pass through to the tanks be above any flood level; that the portion of the premises where any such manhole covers and pipe connections are situated be surrounded by a dwarf wall 2 ft. high and 9 in. thick, and that the spirit pump and pipe connections for the tank barges be fixed inside this enclosure.

(iv.) That the surface drainage of the wharf be passed through a petroleum interceptor approved by the Council.

(v.) That the filling of the cans, drums, and barrels be carried on in the fire-resisting building marked filling-house.

(vi.) That the filling of the cans, etc., be done by pumping the spirit from the storage tanks into three overhead service tanks, each of 400 gallons capacity, fixed in the filling house, and fitted with overflow and emptying pipes returning to the storage tanks, the spirit to flow from such service tanks through iron piping to suitable filling apparatus so designed as to secure the minimum exposure of the spirit.

(vii.) That the filled vessels be stored in a fire-resisting store erected in the position marked on the plans.

(viii.) That the road tank waggons be filled by pumping the spirit from the storage tanks to two filling standards to be erected in the covered enclosure marked on the plans, the surface of such enclosure to be suitably paved and sunk so as to retain any spilled spirit.

(ix.) That, for the purpose of spraying the interior of cans, the spirit be run from a separate service tank of 100 gallons capacity, fitted in an approved

position in an approved manner, through iron piping, to an approved can-spraying trough fixed in the filling-house.

(x.) That due provision be made to the satisfaction of the Council to prevent outflow from any portion of the premises where petroleum (whether spirit or oil) is stored or handled.

(xi.) That the storage of oil on the wharf be confined to the oil enclosure marked on the plans, and that no additional oil tanks be installed without the consent of the Council in writing.

(xii.) That only fire-resisting materials be used in constructing the tank waggon filling enclosure and the proposed lean-to on the south wall of the filling-house, and in adapting or fitting up the existing oil filling-house for spirit-filling purposes, that all existing woodwork be removed, and that the floor of such filling-house be sunk to a sufficient depth to retain all spirit in filling-house, but not sunk lower than 8 in. below the lowest openings in the walls, and that there be no openings in the north and west walls of the filling-house except ventilating openings, covered with fine wire gauze, in approved positions.

(xiii.) That a brick wall 10 ft. high and with no openings therein be erected at the rear of the tank waggon filling enclosure as shown on the plans.

(xiv.) That the premises be artificially lighted by incandescent electric lamps with double globes, that all electric wiring be carried in metal conduits, and that all electric switches be placed in approved positions.

DETAIL OF FIREPLACE AT APPLETON CROSS.

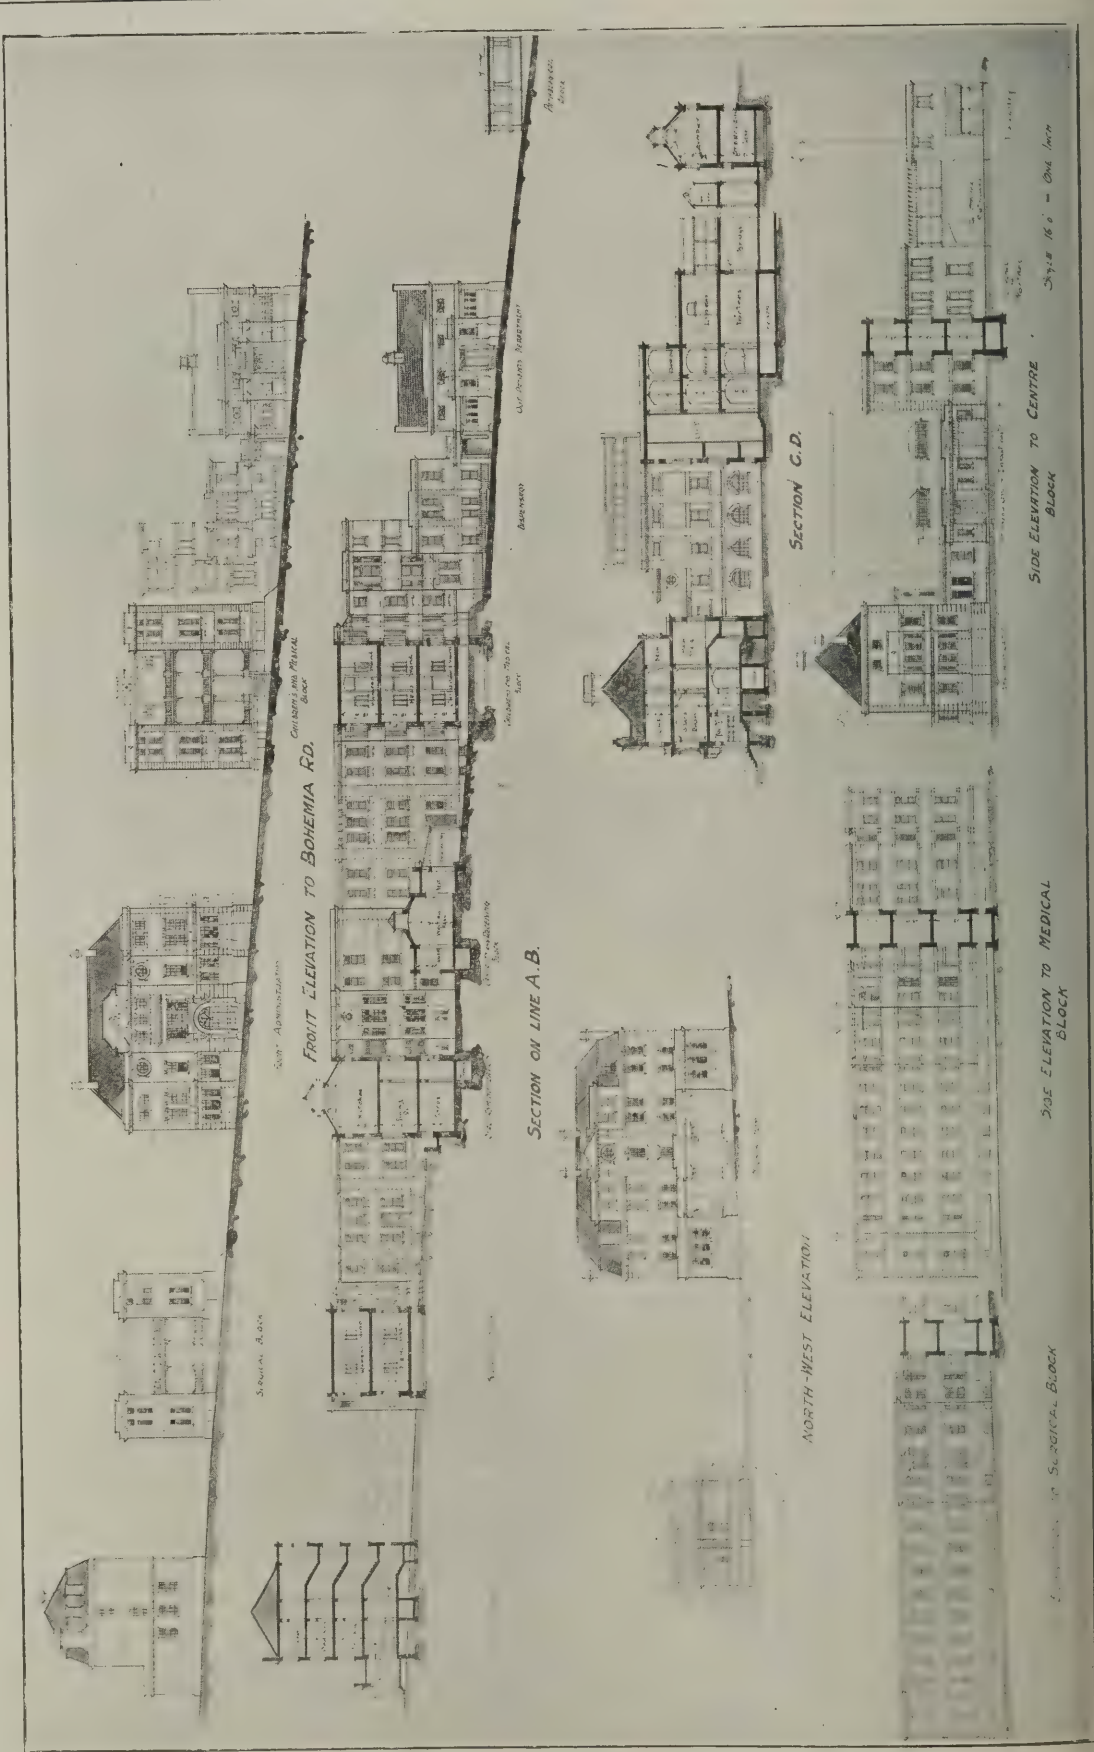

(xv.) That fire, flame, or such artificial light as will ignite inflammable vapour be not allowed within 50 ft. of the places where petroleum spirit is kept or handled.

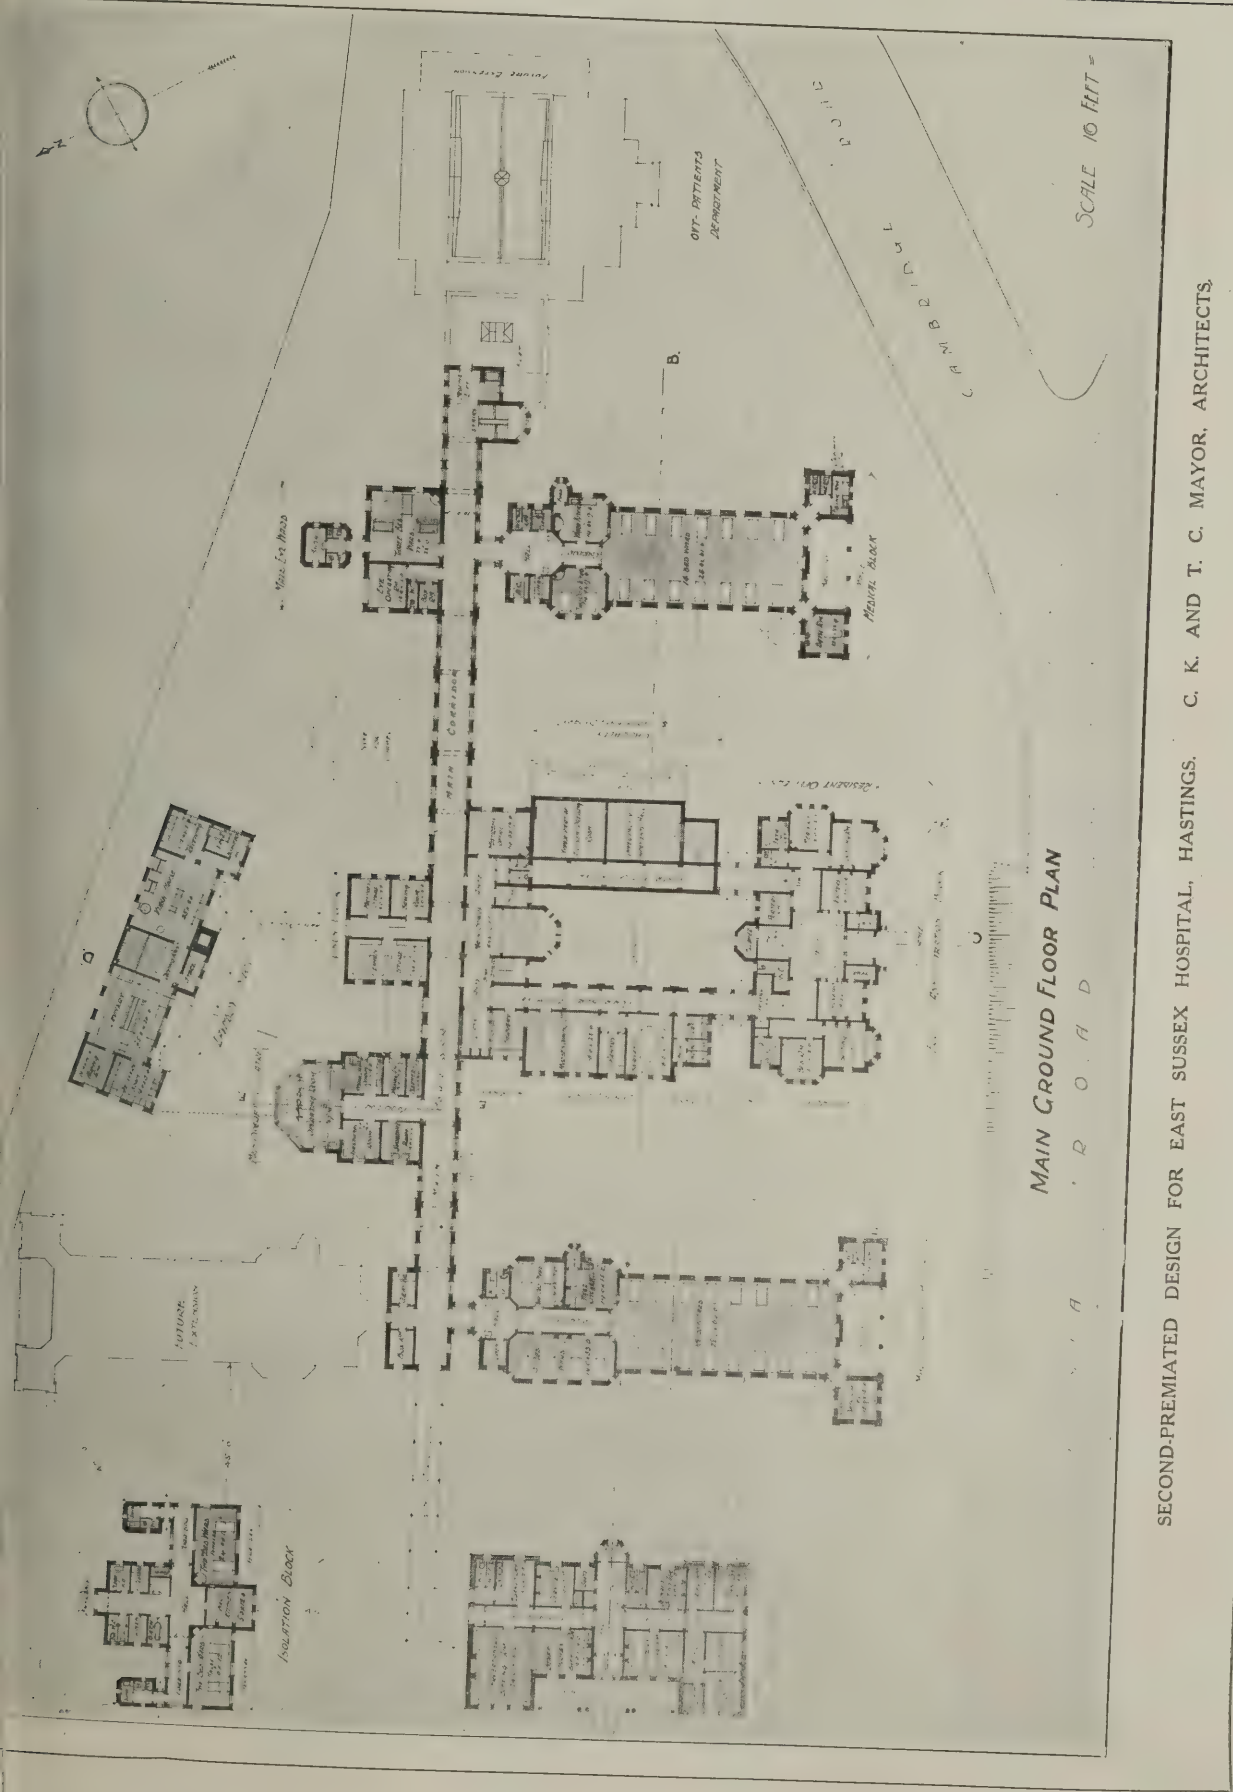

(xvi.) That the petroleum spirit conveyed from the premises be subject to conditions as to conveyance approved by the Council.

AN ADAM PERIOD FIREPLACE.

The fireplace shown on this page by a detail photograph and a measured drawing by Mr. F. J. Barnish has been discovered recently in a house at Appleton Cross, about four miles from Warrington. It is, apparently, of the Adam period, though the date cannot be definitely attributed.

SOME REMINISCENCES BY MR. LEONARD STOKES.*

A year ago, I made a promise which I am breaking to-night. I remember it if you do not, so I am not going to plead forgetfulness, but only that I have been advised that my promise was an unwise one, which had better not have been made, and so had better not be kept.

As I have failed therefore to produce for you an address to students, from a student, I will try to take myself back rather more than a quarter of a century to my own student days, and tell you, if I may, a few of my own experiences and mistakes; for though at the time I was not of an age when mistakes are generally made, or, at any rate, admitted, yet now I can see very well that I was not quite so infallible as I thought myself to be at the time. Take warning, therefore, and remember that it has been very truly said that even the youngest of us may make a mistake!

Well, my first one was that I began my architectural life much too young, and without proper preparation; but as my health broke down time after time at school, and as I had a taste for building rabbit-hutches and drawing tracery-windows with a pair of compasses, a kind friend suggested that an architect's office was a nice easy place to be in—he was by way of being an architect himself, and should have known better—and that as no examinations were necessary, I could easily become an architect!

So without more ado I was articled for three years. There may have been some excuse in my case, but from personal experience I can say that no young architect should begin his career without a thoroughly good all-round education. Whether, from an architectural point of view, he should go to one of the universities or not I am not prepared to say; but from a worldly aspect I feel sure he would be wise to do so.

But to return to my mistakes. The first thing my master, who was quite a good architect in his way, asked me was, whether I preferred Gothic or Classic architecture. Well, I thought of my rabbit-hutches, and my tracery-windows, and answered "Gothic!" The result was not what I expected, for I was set to cut my teeth on "the Orders," and as I could not use my instruments at all properly, you may imagine what I made of them. Of course I should have been taught to draw, and a good many other things besides, before I ever tackled "the Orders" at all—as is now so well done in architectural schools—but as a matter of fact, after the first few months I never looked at them again—at least not for many a long year.

My master was an old Architectural Association man and a great believer in that body, so I was told I must join and look forward to holding some office in it as he had done. That was my first ambition. Well, the "Brown Book" was studied, and, as the subjects in the Advanced Class of Design seemed easier than those in the Elementary Class, plunged into the Advanced Class without more ado, which, of course, was a great mistake, for whereas my first design was for a cricket pavilion—which taught me next to nothing—I might have been put through my facings on "an Atrium to a Roman House" in the Elementary Class,

for which I should have had to look up some authorities, and go into the subject properly and refer to my old friends "the Orders." But not having had any proper schooling, I must needs try a short cut to architectural fame!

This, of course, was the greatest of all mistakes, for the older I get the more certain I am that a good grounding in things architectural is absolutely necessary; so, if you will be advised by me, you won't try any short cuts whatever, but go steadily on up the ladder, round by round, from the bottom to the top; and if, on looking back, you remember having on occasions taken two or three rounds at one time, go back at once, however near the top you may be, and go over them again, one at a time, before it is too late, for we cannot be too thorough in our studies if we want to be authorities in after life.

And if we want to be thorough we must cultivate our observation on all occasions. In my nursery days I well remember a little story we were very fond of, called "Eyes and No Eyes." There was a good little boy—"Eyes"—who noticed everything, and his walks were full of interest, for he saw the cows milked, heard the birds sing, and smelt the flowers, whereas "No Eyes" came home having been impressed only by the hardness of the road and the length of his walk!

Now life is full of "Eyes" and "No Eyes"—principally "No Eyes"—and the "Eyes" get on and "No Eyes" do the reverse, particularly amongst architects, for what are we without observation? Is not our one way of learning how to produce desired effects to find out how others have done what we want to do, and to make quite sure how they did it? Do we not measure every inch of the admired object so that we may have it on paper, and by comparing the drawing with the original make ourselves able to judge work the other way round—that is, by beginning with our paper work, knowing in our mind's eye what it will look like when produced in bricks and mortar? "Eyes" can do this; "No Eyes" can't.

Of course a sense of proportion is a very valuable gift. Whether it can be taught or not I should not like to say; but observation will help us a great deal, and not only observation of the object itself, but also of its position, material, and surroundings, for it is obvious that a slender column which might look right in a screen would look quite wrong carrying a large building, so that we must use judgment with such rules as we have, and to get judgment I contend we must train our own eyes and not depend on other people's.

My three years of pupilage being over, I went by advice into a quantity surveyor's office for a year; and perhaps the only thing I ever learnt thoroughly in my life was how to "square dimensions"! for I spent "six months' hard" at it. I also learnt how to tick abstracts and a few other accomplishments which have been of no use to me since, except that I now have a general idea of what there should be in a bill of quantities—only too often to find that it is not there!

While in the surveyor's office I had a month's holiday, which I used largely in measuring up a fine old church, the drawings of which got me into the Architectural School at the Royal Academy as a probationer, but of course when I got into the schools I found that I knew much more than my masters,—a fatal thing, but I was still very young!

The teaching in those days, however, was a very perfunctory performance. Each student got—if he was lucky—a few minutes' criticism once a week from the visitor! While, in my case, what I wanted was solid hours of instruction! But I suppose it was my own fault for going to the wrong shop?

While in the schools, I made several vain attempts to win a big prize. The first time I think I might have had a chance, but for a much better and more elaborate design. This elaborate design not only lost me that prize but perhaps the next one also. For the second time I thought that elaboration evidently fetched the R.A.'s, so I would be elaborate, and I was! But Leighton, in giving out the prizes, said there was a want of "expressional fitness" about some of the designs—and there no doubt was! Elaboration had failed, so next time "expressional fitness" was my one idea! But this did not come off either! The mistake I made after my first attempt, was not going quietly on doing the best I could without any regard to my judges, or, at any rate, to my idea of them.

Take warning, therefore, and never—whatever you do—either play up—or down!—to your judges, even if they are the Council of the R.I.B.A. Do justice to yourself and yourself only, and never bother about anyone else—until you get a client; and then, unless you have luck, you may perhaps even wish you hadn't got him.

After I had finished my year's quantity surveying—that is, about the time I got into the Academy Schools—I went for nearly a year as clerk of the works on a big building, and saw a certain amount of life and its wicked ways in the building line; and then about another year or so at office work, during which time I won my only prize—the Pugin—more by good luck than anything else, for there were two other men better than I was, but they were so equal that the judges could not make up their minds which was the better, so they gave it to me!—much to my surprise, for although I had sent in some good honest work I knew that either of the two other men was more likely to get it than I was, but I wanted to get my hand in, for perhaps the following year.

Another mistake I made was to avoid the examinations established by this Institute by joining as an Associate amongst the last batch who were elected without examination, instead of even then taking to my books and fitting myself in the only right way—for a youngster—to become a member of this Institute.

I have now described to you my student days proper, and will let you off the old platitudes about being a student all my life. The only thing that I have omitted to mention is that for about three months in each of four years I travelled; twice in England and twice on the Continent, my only regret being that the bulk of my work was not more serious and not quite so sketchy; but in common with other students my eye was caught by bits of pretty detail, and, instead of worrying out the general scheme and construction of a fine piece of work, some dodgy little corner which made a pretty sketch was too often selected.

Now the lesson I want you to learn from all this is that I was too young, and not half equipped for anything, at the time I attempted it, and that I drifted into practice long before I should

reater advantage and profit to yourselves
s students.

CRITICISM OF DRAWINGS SUBMITTED FOR THE INSTITUTE PRIZES AND STUDENTSHIPS, 1911-12.*

BY GERALD HORSLEY, F.R.I.B.A.

The Essays.

In the course of his observations, of
which only a modicum can be here repro-
duced, Mr. Horsley said that time had not
permitted him to read the essays which were
submitted; but he was indebted to Mr.
Reginald Blomfield, who took part this
year in judging them, for some valuable
marks concerning them. These re-
marks Mr. Horsley read, as he was sure
they would influence our younger writers
on architectural subjects to cultivate a
clear, simple, and direct style of writing.
Mr. Blomfield was quoted as saying:
"The essays sent in for the Institute
Silver Medal were unequal. Some of them
were irrelevant to the subject, but that
part in by 'Redundancy,' to which the
prize is awarded, is an exhaustive and
thoughtful essay on a difficult subject,
and has well earned the prize. Certain
serious literary faults appear in the
majority of these essays, such as a tendency
to rhetoric which fails of its pur-
pose; a habit of powdering the essay
with quotations from every possible
writer, poets, essayists, and others, many
of them having little or no bearing on the
points under consideration, flippancy and
familiarity in style, occasional lapses
in grammar, and, lastly, a mistaken
conception of what either an essay or a
book should be. Many of these essays
are mere strings of classification; the
subject is divided and subdivided till it
is lost out like a river lost among the sands.
A central idea emerges as a result of all
this industry, and the writer appears to
forget that an essay or a book should be an
organic composition, with a beginning,
middle, and end, and a backbone of some
unite idea running through the whole.
The object of these essays is not a display
of literary fireworks, but the clear and
logical presentation of the ideas and
conclusions that result from the careful
study of facts. The art of the writer
should not obtrude itself; it is shown in
the orderly marshalling of his forces, in the
clarity and precision of his statement,
and in a certain suppressed emotion that
expresses the deeper harmonies of his music.
The method of writing which shocks and
annoys is wrong. It is with writers as with
artists; the best are those who make
no parade of their technique." Mr.
Horsley recommended this excellent
criticism to the consideration of all
architectural students.

The Soane Medallion.

Turning to the drawings, the author
commented upon a certain weakness in
the design section, and a certain strength
in the studies in ancient architecture.
The fact that this year the Soane Medal-
lion has not been awarded supports this
view. The strength in the design section
was in the excellent work submitted by
the winner of the Tite Prize. The way
in which he has solved the problem
presented for solution, and the quality of

his drawings, should be particularly
noticed. He has best fulfilled the pur-
pose of this competition, which is to pro-
duce a fine design finely drawn. The
Soane Medallion is not awarded this year
for the reason that no one of the designs
shows a real grasp of the conditions
governing the competition, nor an entirely
satisfactory solution of the problem.
The Council decided, in consequence, to
bracket together the two designs under
the mottoes "Circle City" and "Ante"
in Honourable Mention, and to divide
the prize of £100 between the authors of
them. The two successful designs repre-
sent two different views of the problem,
and neither has wholly succeeded.

"Vista," in Mr. Horsley's opinion,
well deserves the certificate of honourable
mention which he has won. "In my
opinion his plan is the best in the com-
petition." Had his elevations and sec-
tions displayed greater powers in design,
this set would have surely earned for its
author a more prominent position. The
chief excellence of the design lies in the
plans; the grouping of the reception-
rooms at the head of the principal stair-
case, between the banqueting-hall and
small hall, on the first floor, is particularly
happy. Again, the Guildhall itself is
admirably placed and excellently designed
for its purpose. The author has evi-
dently paid special attention to the many
details in accommodation necessary for a
building of this important character.
He is especially successful in providing
ample platform accommodation both in the
large and small halls. This important
matter has been generally rather over-
looked in the other plans in the room,
the grand organ and orchestra having
frequently been obliged to be content
with very inadequate space and accom-
modation. It is unfortunate that the
drawings in this set are rather too black
and too coarsely executed. Probably
the author desired to make his work
"tell," and used this method accordingly.
Mr. Horsley considered that view to be
a mistaken one. Drawings which are
delicately and beautifully drawn are
more attractive and more helpful in
portraying a design.

The Tite Prize.

After briefly criticising the work of
the remaining candidates for the Soane
Medallion, Mr. Horsley turned to the
drawings submitted for the Tite Prize.
Referring to the excellent work provided
by the winner, Mr. Louis de Soissons,
he said that the plan is admirable for
the purpose—namely, the central court-
yard of a Royal Exchange. It is thor-
oughly well thought out, stately, with
ample and dignified entrances. The
courtyard itself is as large as possible, a
first consideration in a Royal Exchange.
The proportions of the building are
exceedingly good, especially in the well-
designed "order" of the interior. The
drawings are beautifully executed, and
gain technically by the careful showing of
the jointing. Their good effect is rather
marred by some signs of hurry in the
detail drawings. The design marked
"The Circle" well deserves its certificate
of honourable mention. It is a well-
drawn set, though rather overtinted in
too sombre and dark a grey; but the
plan is beautifully drawn, and so also is
the sheet of $\frac{1}{4}$ -full-size details. The whole
design is a thoroughly interesting study,
and by its close following of Italian
detail keeps strictly within the expressed
intention of the competition.

On leaving the consideration of these
drawings for the Soane Medallion and the

Tite Prize, Mr. Horsley, after detailed
criticism of the work of the several
candidates, congratulated the Royal In-
stitute upon its recent decision to make a
competition in design one of the com-
pulsory features in its final examination.
This competition, he said, will oblige the
student in the future to study design
systematically. Every architect who
has seen the good work done by young
students in French ateliers in the *petits
concours*, or sketch design competitions so
frequently held there, will surely hope such
trials of strength may be more frequent
among our own students. Even in the
case of the youngest it is no bad thing
to encourage him sometimes to "hitch
his wagon to a star," or "dip his pencil
in the hues of the rainbow."

The Grissell Gold Medal.

In the competition for the Grissell
Gold Medal four competitors have entered.
To "MCMXII." the prize has been
awarded. Undoubtedly this design best
fulfils the requirements of this com-
petition. The construction is extremely
well adapted to a temporary building,
and the plan is quite good, though,
personally, Mr. Horsley would prefer a
more dignified architectural treatment for
the housing of an art exhibition. "Fer-
dans blanc-mange," by his choice of
material—namely, reinforced concrete—
has put himself out of court, as it can
hardly be called one which is suitable for
a temporary building.

The Measured Drawings.

The Measured Drawings Prize and
Silver Medal competition was a very
good one. Five sets of drawings were
submitted, and after a careful study of
them and a scrutiny of the measured
work and sketches done on the spot, one
feels that Mr. Maxwell has well earned
the prize. His portfolio of measured
studies is an admirable example of what
such a collection should be. Taken
together with his finished drawings, it
shows that his study of this beautiful
old house, Compton Wynates, has been
thorough and exhaustive. In making
his survey sympathetic and complete he
has realised more than any of the other
competitors the special purpose of this
prize—namely, to encourage a compre-
hensive and highly intelligent study of
an ancient building of importance. The
result is that he has produced a set of
drawings in a manner worthy of the
interesting example of English archi-
tecture he chose to study. Mr. Horsley
thought, however, that attention should
be drawn to the fact that the finished
drawings consist of mounted tracings from
drawings made on the spot.* Mr. Horsley
thought that such a practice was to be
strongly deprecated, for the reason that
tracing-paper, however well mounted, is a
fragile material of little natural per-
manence. Measured drawings of this
importance may pass into our national
collections, such as that at South Ken-
sington, and should be on sound English
drawing paper. The two competitors
who received honourable mention both
submitted sets of drawings of great merit.
The technical excellence of their work is
very good. "Arno" has particularly
distinguished himself in his detail-drawing
and in a perspective sketch. It would
have been possible to commend these two
sets more highly had the original surveys
made on the spot in both cases shown
better evidence of a closer investigation
of the essential qualities of the buildings.

*It has been explained that the paper used is
"tough English bank."

The Pugin Studentship.

The drawings submitted for this prize show a very high degree of merit. Mr. James Macgregor has won the first place by the excellent quality of his workmanship and full set of drawings. His perspective diagram of the interior of Sherborne Abbey is to be especially commended. Mr. Norman Mackellar shows an excellent study of Durham Cathedral; a model study for a Pugin Student, and a proper subject for competition for the Measured Drawings Prize. Mr. W. J. P. Jones submits some excellent drawings, particularly of Stokesay Castle and some foreign subjects. In the choice of the latter he has strayed from the strict conditions of the competition. Mr. Anderson and Mr. Leathart have also been honourably mentioned; the former has good work from Lincoln and Southwell, and the latter very good representations of carved and coloured woodwork.

The Owen Jones Studentship.

It is regrettable that a studentship of this importance and value should have attracted but two candidates. The competitors have spent too much time upon very elaborately worked figure painting and facsimile representation, although in doing this they show quite remarkable excellence. It should be remembered that the object of the competition is to test the competitor's acquaintance with the disposition of colour in such a way as to enhance architectural effect, and to beautify the building by colour and such ornament as may assist in this result. Correct drawing of the figure is important, but not so much the painter's skill in execution. The drawings of both competitors show much ability.

The Arthur Cates Prize.

Mr. J. B. F. Cowper has deservedly succeeded in winning this excellent prize with a fine collection of sketches and measured drawings, chiefly of mediæval work. The competition generally is weak in its representation of studies in classical and Renaissance architecture. One may hope that in the future the competitors for this prize will pay more attention to these periods.

[The official list of awards was given in our issue of January 31st, p. 123.]

DISCUSSION.

Sir Henry Miers, of London University, proposing a vote of thanks, said that the president had shown himself to be an artist in words as well as in stone. At London University, he continued, they hoped to establish a strong school of architecture, and in this work they would greatly value the advice of the Institute. He included Mr. Horsley in the vote of thanks for his sympathetic, searching, and excellent criticism of the drawings on the walls. They hoped to have a new building for the University, and he trusted that the Institute would provide an architect who would design a building worthy of its purpose.

Sir Alfred Keogh, Rector of the Imperial College of Science and Technology, said that, as the head of a great institution, it was natural that Sir Henry Miers should refer to the effort now being made to found a great school of architecture in London. He, too, would like to say something on the subject of education. Although, to a slighter extent, his college had some intimacy with architecture—on a subject which had been somewhat neglected in the past. The desirability of a better acquaintance with scientific work had long been recognised by that Institute; and efforts were now being made at the Imperial College to meet the

need. He hoped they would thus take some part in providing for the efficiency of the architectural profession.

**BUILDING INTERESTS IN
SOUTH AFRICA.**

*Specially written by our South Africa
Correspondent.*

JOHANNESBURG, January 15th, 1912.
The Building Boom.

I am able to give your readers some very interesting figures supplied by the Municipal Surveyor's office of Johannesburg regarding the extraordinary activity there has been in the building trade here. Throughout last year 3,665 plans were approved, these affecting 8,028 separate buildings and tenements, against a total of 6,652 for 1910. It is estimated that accommodation is provided for 12,608 Europeans and 4,312 natives, whilst the cost of construction is put down at £1,810,754.

The total for last year exceeds that for the previous year by no less a sum than £464,994. It will be seen that in a period of two years over £3,000,000 has been put in bricks and mortar and wood and iron in Johannesburg. Since June, 1907, plans have been approved for 25,599 separate buildings and tenements, the total cost of construction being £4,382,534.

New Pretoria.

Nowhere has there been such a transformation as in Pretoria. The Union Government buildings are rising up as one of the grandest piles in South Africa. The capital will also soon possess the finest railway station in the Union. It is situated at the top of Market Street, to the east of the existing railway terminus, and its completion is involving the construction of a new roadway by the Municipality, and an extension of the car lines to the entrance to the station itself. Mr. Herbert Baker is the architect of the structure, and Messrs. Prentice and Makie are the contractors, both firms also being associated with the Union buildings. The station has a frontage of 208 ft., and covers an area of 28,000 sq. ft. It is built of local granite. I have already described the other great improvements which are taking place in Pretoria, which are really transforming the place into a veritable city of palaces.

The Coloured Artisan.

This is a subject that I have touched upon several times. A friend writes in a way that puts the matter very clearly. He says: "The inroad of the coloured man into the field of unskilled labour has of late been the cause of considerable anxiety to the white population. With his advent the scale of wages must inevitably fall, and unless some remedy is found to check the black invasion, a state of matters similar to that prevailing in Cape Colony will soon be found throughout the Transvaal. No one who desires a white South Africa can view the prospect without deep concern."

The Art Gallery.

The foundation stone of the new Art Gallery for Johannesburg, as designed by Mr. E. L. Lutyens, F.R.I.B.A., was laid a few months ago, and a start is now being made. It will be a magnificent building situated in Joubert Park. The cleverness of the design rests in the adaptation of the style to South African climatic conditions, and this is impressed by the ingeniously devised top lighting of the picture galleries. The plans in themselves are an inspiration, and their realisation will produce a building which

will be decidedly worthy of its purpose. Mr. Robert Howden, President of the local Architects' Association, and Mr. Herbert Baker, the distinguished architect who designed the Union Buildings, will, it is understood, superintend the work.

A Johannesburg Retrospect.

The following building retrospect for 1911, taken from the "Master Builder Journal," sums up succinctly the position of the building trade in Johannesburg. "The two outstanding features of the year have been the transformation of the central part of the town and the enormous amount of building in the outlying suburbs. Most building activity has taken place in Eloff and Joubert Streets, where Messrs. Norman Anstey's, Chudleigh's, and the African City Properties Trust have erected huge premises, while in the near future the Union Club and Y.M.C.A. building will further add to the attractions of this neighbourhood. Besides the above structures, the Orpheum and Bijou Theatres are also prominent in the vicinity. During the year more places of amusement have been built than in any previous year of the Rand's history, besides the two above-mentioned theatres the Grand, Lyric, Coliseum, and Niagara have opened their doors to the public. The latter has by far the largest hall in the country, and is capable of seating 5,000 people."

Distributing Centre.

"As Johannesburg has become the greatest distributing centre of the Union many large wholesale firms have increased their accommodation. . . . Further afield, the most noticeable feature has been the building up of the Berea and Houghton Estate. These two suburbs have become the educational centre of the town, at the King Edward VII. High School, John's College, and Girls' High School now being built in Barnato Park. Messrs. Clark and Sons, are not only magnificent buildings, but afford facilities for education equal to anything to be found in England. That they have proved a strong magnet is conclusively shown by the many fine villas surrounding them."

Important Buildings.

"Among public buildings the most important opened during the year were the Law Courts in Von Brandis Square, while a commencement has at length been made with the long-deferred Town Hall. As regards such works as drainage, street construction, etc., the Municipality has pursued the even tenor of its way, and has done quiet but unobtrusive work. The centre of Johannesburg is being kerbed and channelled at a cost of £100,000. Particular attention has been paid to road construction, and the majority of the eight hundred miles of streets are in excellent condition. The drainage scheme is being pushed forward steadily, and continuous work is carried out, mostly in small sections, so that the centre of the town enjoys the advantage of the water-borne system. Taken as a whole, Johannesburg contractors have little cause for complaint as regards the amount of work that came forward during 1911, and there is every indication that the coming year will see but little diminution in this respect."

THE ROYAL GOLD MEDALLIST.

At the meeting of the R.I.B.A. held on February 5th, the nomination was announced of Mr. Basil Champneys as a fit recipient of the Royal Gold Medal. The election will take place on March 4th.

NEWS ITEMS.

King Edward Monument at Cannes.

The monument which is to be erected at Cannes to the memory of King Edward VII. is the work of MM. D. Puech and D. Daumet, and is to be inaugurated towards the close of March.

Business Appointments.

Mr. L. Serrailier, manager, and Mr. R. W. Vawdrey, chief engineer, of the Indented Bar and Concrete Engineering Co., Ltd., Queen Anne's Chambers, Westminster, have been appointed directors of that company.

Workmen's Dwellings for Paris.

Baron Gustave de Rothschild has bequeathed to the Rothschild Foundation in Paris for the improvement of the condition of the working classes the sum of £40,000 to be spent in the purchase of land in or near Paris, on which are to be erected workmen's dwelling-houses.

Osram Lamps for the Post Office.

The General Electric Co., Ltd., have again obtained the contract for supplying the Post Office with metallic filament lamps during the next six months. The contract covers every type of Osram lamp for which they tendered from the 5 c.p., 25 volts. size upwards, and including 100 c.p. lamps.

Australian Commonwealth Offices in Aldwych.

A cablegram has been received by the Australian Government from the High Commissioner in London, announcing that he has appointed Messrs. Marshall Mackenzie and Son, architects, of Victoria Street, Westminster, to design the building for the Commonwealth Offices on the Aldwych site in the Strand.

Change of Address.

Messrs. Crosby Lockwood and Son, 7, Stationers' Hall Court, E.C., etc., announce that they have transferred their Technical Book Room from 121a, Victoria Street, to more commodious premises at No. 5, Broadway, Westminster, S.W. (opposite Vickers House), where a full representative stock of all the latest and most important engineering, technical, building, etc., books may be inspected.

Ruskin College, Oxford.

The foundation stones of the new buildings of the college in Walton Street were laid last week. The buildings will cost something over £9,000, and will consist of a hall, to be known as the Buxton Memorial Hall, in memory of the late Mr. C. S. Buxton, formerly Vice-Principal of the College, who bequeathed £5,000 to it unconditionally; a large lecture room; accommodation for fifty students; and a Vice-Principal's residence. Mr. Basil Champneys is the architect.

Wimbledon House Estate.

This estate, the remaining portion of which is to be put up to auction on February 24th by Messrs. Hampton and Sons, of Cockspur Street and Wimbledon, has had distinguished tenants. In 1791 it was sold to M. Calonne, who had been Prime Minister of France under Louis XVI. M. Calonne sold the property to Earl Gower, afterwards Marquis of Stafford. Louis de Bourbon, Prince of Condé, took refuge here in 1810, and eight years later the property was

acquired by the father of Captain Marryat the novelist. The forthcoming sale of the remaining portion of the estate, in sixty-one large and small plots, should make a strong appeal to builders, architects, and speculators.

New York's Water Supply.

The two great divisions of the Catskill aqueduct tunnel under the Hudson River at Storm King Mountain have been united, Mayor Gaynor having fired the blasting charge removing the last wall of the rock between the borings. The Mayor and his party were lowered to the shaft 1,100 ft. below the river, and walked thence to the point where the two sections were to be joined. The floor levels of the borings and the side walls met within a fraction of an inch. The new water system, which is acclaimed as one of the world's greatest engineering feats, is expected to be finished by 1913, and will supply the city with 500,000,000 additional gallons daily.

Glasgow Cathedral Roof.

Messrs. Geo. Laird and Son, the contractors for the re-roofing of Glasgow Cathedral, make the interesting statement that all the old oak that they have taken down is being retained by H.M. Commissioners of Works. Part of it, having been in the roof for about 750 years, is so decayed as to be useless, but a large part, when the surface decay has been removed, is thoroughly sound and good, notwithstanding its great age. Of this part a large number of the carved bosses have been made, and will be seen later on in the choir and transept roofs. They add that about thirty years ago they made a table for the Senate room of Glasgow University to the order of the late Professor Robertson, the thistle carved panels of which were made of old oak which was taken out of the north transept of the Cathedral in 1846.

Bessemer Memorial Laboratory.

The Bessemer Laboratory, which was formally opened by Sir Charles Allen, in the absence of Sir William Preece, at South Kensington last week, is a memorial to the late Sir Henry Bessemer, the inventor of the metallurgical process which bears his name, and it occupies a portion of the new building of the Royal School of Mines, which when finished will have cost about £150,000. The mining profession has already subscribed about £20,000 to commemorate the achievements of the great inventor, and this sum has provided an equipment which is believed to be unequalled in any educational institution of its kind in the world. This equipment is not yet complete, but the plant already installed will allow of the experimental treatment of ores by all the processes usually found in operation in mines. While the new laboratory will be an invaluable aid to the students in the mining school, for whom it is primarily intended, its use will not be confined to them. It has been decided to allow it to be used for private investigations by professional men, whose work and association with the school will, it is anticipated, be of no little advantage to the students themselves. The laboratory is a low, glass-covered building, occupying a considerable area of ground, and it is so constructed that the maximum of light is obtained, while ample space is left around the machines, which are worked under conditions approaching closely to those of practical mill work.

SOCIETIES AND INSTITUTIONS

LIVERPOOL ARCHITECTURAL
SOCIETY*The Old Buildings of Snowdonia.*

On taking the chair of the fifth ordinary sessional meeting of the Liverpool Architectural Society, last week, Mr. A. Thorneley (president) reminded the members of the invitation of the Birmingham Architectural Association to inspect the New Art Galleries of that city on February 23rd. He called upon Mr. Herbert L. North to read a paper on "The Old Buildings of Snowdonia." The lecturer, having remarked that the simple types of buildings in Snowdonia harmonised with the varied landscape, recommended visits to North Wales in winter, the aspect of the country being at present glorious. He proceeded to describe the early and square Celtic churches and to trace the introduction of chancels by the Latin monks, after which he illustrated the development of domestic architecture.

THE CONCRETE INSTITUTE.

A meeting of the Concrete Institute took place at Denison House, 296, Vauxhall Bridge Road, Westminster, S.W., on February 8th, Sir Henry Tanner, C.B., I.S.O., F.R.I.B.A., presiding. The following were elected members: Mr. Ewart S. Andrews, B.Sc., London; Mr. H. Percy Boulnois, M.Inst.C.E., F.R.San.I. P.P.I.Mun. and County E., London; Mr. David Donaldson, London; Mr. William E. J. Fett, Hull; Mr. James A. Malcolm, London; Mr. L. R. Nicol, Padstow, Cornwall; Mr. George S. Roberts, London; Mr. J. Vaughan Stewart, jun., Lebu, Chile. It was announced that the Council had admitted Mr. Wilfrid Lever, of Ashton-under-Lyne, as a student.

A paper by Professor Beresford Pite, F.R.I.B.A., entitled "The Aesthetic Treatment of Concrete," read at the summer meeting, was submitted for discussion, in which the following took part:—Mr. Arthur T. Bolton, F.R.I.B.A.; Mr. E. Fiander Etchells, F.Phys.Soc.; Mr. A. Alban H. Scott, M.S.A.; Mr. L. Serrailier; Mr. Herbert Shepherd, A.R.I.B.A.; Sir Henry Tanner, C.B.; and Mr. E. P. Wells, J.P.

LOWER THAMES VALLEY DISTRICT
SURVEYORS' ASSOCIATION.

A well-attended meeting of the above association was held at the Town Hall, Twickenham, on February 3rd, when the president, Mr. Edward Willis, A.M.I.C.E. (engineer and surveyor to the Chiswick Urban District Council), presided.

The association had under consideration the effect of motor-omnibus and similar traffic on roads which were not constructed for this class of traffic, and passed a resolution with regard to the same, and forwarded a copy to the Institution of Municipal and County Engineers for their consideration.

The discussion was continued of Mr. Jeffes's paper entitled "Some Notes on the Construction, Laying-out, and Making-up of Private Streets." The discussion was further adjourned until the next meeting.

The association also had under consideration the question of advertisement signs of all classes, and this topic was discussed at considerable length.

YORKSHIRE FEDERATION OF
BUILDING TRADES EMPLOYERS.

The monthly meeting of the executive council of this Federation was held in the Town Hall, Bradford, on January 18th, when Mr. J. Townsley, president, occupied the chair, and was supported by forty-six delegates from the federated associations.

It was reported that a protest with reference to the National Insurance Act had been supplied to all the local associations affiliated with the Federation, together with all kindred building trade associations in Yorkshire.

It was decided to request Government departments, local authorities, and architectural societies to include an item in all quantities in future to cover the increased charges for workmen imposed by recent legislation, and that the National Federation be invited to take similar action to secure uniformity.

It was resolved that difficulties having been experienced in Yorkshire with reference to the employment of non-unionists, this Federation affirms that freedom of employment is of vital importance to employers, and requests the National Federation to endorse this principle.

It was reported that notices had been received from the operative societies in the following cases: *Bradford and Shipley, joiners.* Increase of wages from 8½d. to 9½d. per hour together with other alterations of rules. *York, joiners.* Notice of increase of wages from 8½d. to 9d. together with other alterations. The local associations were instructed to take the notices into careful consideration, and inform the Federation whether there is any matter upon which their assistance would be helpful or their intervention was desired.

It was reported that the Bridlington Association had consented to an increase of wages to labourers from 5d. per hour to 5½d.

It was reported that the Huddersfield Corporation had requested the Federation to supply them with a copy of the letter and enclosure which had been submitted for their consideration on the subject of contractual referees, in respect of public contracts. These had been supplied, and it was hoped that as a result the request for the incorporation of an independent arbitration clause would receive equitable and favourable consideration.

Attention was drawn to the revised fair trades clause as recently adopted by the West Riding County Council, and particular notice was drawn to the fact that the clause incorporated a provision, "but it shall not be a condition that trade union men only shall be employed." It was stated that a copy of the revised clause would be forwarded to the local secretaries and representatives in order that members may be made aware of the new provisions.—Condensed from report supplied by J. DAVIDSON, secretary.

BARROW-IN-FURNESS MASTER BUILDERS'
ASSOCIATION.

The annual meeting of the above association was held on January 30th, when, after the usual routine business, the election of officers resulted as follows: President, Mr. Edgar Banks; vice-president, Mr. Wm. Morris; secretary, and treasurer, Mr. J. Baker; auditors, Messrs. R. F. Miller and Co., C.A.

Negotiations are pending with the joiners, bricklayers, plumbers, and painters in respect to an advance in wages and the question of boundaries.—Condensed from a report supplied by J. BAKER, secretary.

DANGEROUS IRON ROOF GUTTERS.

A correspondent asks whether it is not time that something should be done to prevent the jerry way these iron gutters are fixed. He complains that, in the absence of any by-law to the contrary, they are fixed any way and by anybody, some with nails, some with screws, against a flat fascia board (and sometimes the board itself not properly secured). In a short time the heads of the nails or screws rust away, the holes in the backs of the gutters become larger, and when a fall of snow takes place the weight of the snow simply pushes the gutter away from the fascia board. The average weight of a 6 ft. length of gutter is about 30 lb., the weight of snow making it much heavier. Fatal accidents from falling gutters have been frequent, and it is suggested that all moulded gutters weighing from 18 lb. upwards be fixed on brackets 1½ in. wide by not less than a quarter of an inch in thickness, and the brackets screwed to the end of the roof spars, or wall plate (in all good jobs this is done). In ordinary light guttering, where there is a fascia board, the board itself should be properly secured and the gutters screwed to it with strong brass screws.

TRADE AND CRAFT.

Hygienic Heating: A New Radiator.

It is generally recognised that electric heaters, either of the radiator or convactor type, form the most healthful means of raising the air of a room to a comfortable temperature. When electric heaters are used, no actual combustion takes place to produce the heat, and the air is not impoverished by loss of oxygen, or made impure by the formation of gases injurious to health. With all forms of artificial heating, however, it is necessary that the air of the room should be renewed at a constant rate, and generally a means of communication with the outside atmosphere should be provided. This is also true with electric heating, not because the air is vitiated, but because any form of heat produces dryness and a loss of humidity. That the air we breathe should possess a certain degree of humidity is necessary to health as well as to comfort. If a person remains in a dry atmosphere for any length of time, an unpleasant feeling is caused in the mouth, and there is produced a general sensation of depression. Any arrangement, therefore, which while heating the air also supplies it with the necessary humidity, must be most suitable. Further, it is important to remember that with electric heating the air is not depleted of its oxygen, and the rate at which the air in a room is changed when using the type of heaters here illustrated need not be any higher than that for the ordinary ventilation required by human beings. A modified form of radiator has been designed to produce the required degree of humidity in the atmosphere. The heaters in question are made up in two and four lamp patterns, and have been introduced by Messrs. Simplex Conduits, Ltd., of 116, Charing Cross Road, W.C., and Garrison Lane, Birmingham.

LONDON'S KING EDWARD
MEMORIAL.

The Mansion House Fund for providing a memorial to King Edward in London now amounts to nearly £68,000, which includes a promised contribution of £5,000 from the receipts of last year's Coronation Exhibition. Mr. Bertram Mackennal, with Mr. Edwin Lutyens, the architect, is making a model of a proposed statue of the King to be erected at the Piccadilly end of the Broad Walk in the Green Park. This will be ready for the inspection of the Mansion House Committee towards the end of this month.

With regard to the scheme which contemplates the acquisition of Shadwell Market and its conversion into a park or open space, the Corporation of the City of London, who are the freeholders, estimate the value of their bondholders' interest in the site at £140,000, but they are willing to transfer that interest to the committee for £73,000. The London County Council, in response to an appeal by Sir Vezev Strong, the chairman of the fund, have agreed to purchase for £14,000 the site it now holds on lease from the Corporation at the market, and to throw in other property worth £4,000. The Poulter Trustees have offered a contribution of £5,000. As there will be a considerable balance in hand—probably £40,000—after the Green Park statue has been erected, the chances that the Shadwell Park scheme will be carried through are exceedingly favourable.

BIRMINGHAM UNIVERSITY TOWN
PLANNING LECTURES.

Mr. Raymond Unwin, F.R.I.B.A., lecturing at the University last week, dealt with the development of town-planning in the city of Paris, explaining how the boulevards of the city sprang up along the line of abandoned fortifications dating from the later part of the 17th century, and how they were very largely extended by the incorporation into the growing town of many parks, drives, and avenues which had been laid out in the country around Paris at the end of the 17th and the beginning of the 18th centuries. The planning of the early American towns was next dealt with, showing how the tradition of the 17th century planning in Europe was carried on in America, the square type of plan being represented by Penn's lay-out of Philadelphia, and the Parisian type of planning being followed by L'Enfant, Washington's engineer, who laid out the capital city of Washington.

The lecturer showed how the gridiron plan for the city, as originally planned, was most inconvenient for the large cities which had developed upon it, and was entailing costly schemes of remodeling such as are being carried out in Philadelphia and are contemplated in Chicago and many other cities. The lecturer illustrated the splendid work that has been done in many of the American cities, securing large areas for parks on the outskirts of the town, reserving for public recreation the sea front and the foreshore of the great lakes for considerable areas, and the creation of parkways or wide boulevards encircling the town and linking up the different parkways one with the other. Notable examples of this enterprising foresight are to be found at Boston, Philadelphia, Chicago, and in Washington itself.

THE ARCHITECTS' & BUILDERS' JOURNAL.

WEDNESDAY,
FEBRUARY 21st, 1912.

Volume XXXV,

No. 892.

SITTING-ROOM BAY, THE MURREL, ABERDOUR, FIFE. F. W. DEAS, F.R.I.B.A., ARCHITECT.

This room faces north-west. The casements are of teak, the tops of the bays being covered with lead. The floor is laid with oak boards in irregular widths.

REREDOS IN LADY CHAPEL, LIVERPOOL CATHEDRAL. G. GILBERT SCOTT, ARCHITECT.

THE ARCHITECTS' & BUILDERS' JOURNAL.

The London Society.

A public meeting on February 9th a society was formally inaugurated which, under the title of "The London Society," is to undertake to bring about the artistic improvement of London. The founding of a society for such an object in a capital city is rather an unusual—we are not sure that it is not an unprecedented—event. In Paris there is the "Vieux Paris" Committee, it is true; but this is a society for protecting ancient work, not for inaugurating modern improvements. Why is it that such an undertaking is considered necessary in London?

The reason seems to be that in London neither the Imperial nor the municipal government concern themselves much with any question of the artistic improvement of the capital. In Paris the artistic improvement of the city is an object of the greatest solicitude both with the State Government and the Municipal Council; so far from requiring any spur to be applied to it in regard to such matters, the Municipal Council of Paris has sometimes been accused, by its own citizens, of putting considerations of æsthetics above those of public convenience and utility; a noble error at all events if there is any ground for the accusation. In London both governments, Imperial and Municipal, are primarily utilitarian in their aspirations. The Imperial government, in fact, hardly intervenes at all in questions concerning the improvement of its capital; that it does nothing to assist was one of the complaints made against it by one speaker, Lord Alexander Thynne, at the meeting in question. There is the Office of Works, certainly; but the Office of Works only intervenes in questions of detail in which sites or monuments which are the property of the Government are concerned; it deals in no large schemes of metropolitan improvement, and in the detailed schemes which have come officially under its hand it has nearly always done the wrong thing, and spoilt the opportunity. One reason for this doubtless is the system of appointing a First Commissioner of Works for political motives, and not because he has any special knowledge or ability in regard to architectural work. The London County Council for one moment woke up to a sense of the æsthetic element in London improvements when it instituted an architectural competition for the treatment of Kingsway and Aldwych; but it quickly took fright at its own efforts when it appeared that they would check the letting or sale of building sites; relapsed into its normal utilitarian attitude; and the great competition failed of any of its expected effects. The City Corporation is even more, and more avowedly, utilitarian; it is contemptuous of those who regard a bridge in any other light than as a roadway for traffic. Some of these people would pull down St. Paul's, if they thought they could improve road communication thereby; they very nearly did succeed in getting St. Mary-le-Strand destroyed, in order to improve the roadway and please the shopkeepers.

In these circumstances the creation of a society which would devote itself especially to the artistic improvement of London would be a great advantage, provided that they

can formulate a definite programme, and (which is after all the main point) that they can command influence enough to get it carried out. What are the Society's distinct aims, and what its influence is likely to be, must be all a matter of conjecture until we know who the committee are to consist of and what are their leading ideas; the opening meeting merely established a resolution to form the society and select an executive committee. Some general indications may, however, be deduced from the discussion which then took place. In regard to the importance of continuity in city improvements, reference was made by one speaker to the interesting fact (not very generally known) that the great schemes of street improvement carried out in Paris by Haussmann, under the Second Empire, were mainly a development of the general lines of a scheme which had been formulated more than a century earlier, and laid down on various tentative plans published from time to time. It was, however, a mistake to credit Haussmann with the Rue de Rivoli, the western portion of which was in fact laid out under Napoleon's orders in 1802; Haussmann merely completed it eastwards; but the record of Paris is valuable as showing how important it is to have long preconceived ideals to work up to. That is what we have never had yet in regard to London.

The special note of the meeting seemed, however, to be the necessity for comprehensive action and a comprehensive scheme. This seems peculiarly necessary in regard to London, owing to its vast extent and the remarkable local differences in what one may call its architectural scenery. As the chairman (Sir Aston Webb) remarked in his speech, the management of London is cut up into so many parts that it is difficult to think of London as a whole, and see what it requires. But it is not only the management—that is a matter of administration; it is the appearance and style of different districts. Whole quarters of London seem to have been laid out and built under one special influence, and according to one special taste or custom; we have the cemented districts, like South Kensington; the plain brick districts, like the Bloomsbury streets; the æsthetic house districts at Chelsea and in the quarters adjoining Sloane Street; and so on. A visitor transported blindfold from one of these districts to another might very well suppose that he had visited so many different towns in different parts of the country. We cannot undo this heterogeneous character of London, except by very slow degrees. What would serve to bind the several parts together into a rational whole would be a comprehensive scheme of street improvement, and the provision in each district of cardinal points whereat might be erected important buildings, referable to some wider and higher standard of architecture than the mere fashion of the district. As the chairman said, town-planning schemes are springing up all over London, and if they are carried out without reference to a great central scheme, confusion will arise. Professor Pite touched on the same idea; London, as he truly remarked, "had been developed haphazard," and those people who loved beautiful things loved them in a disorganised way; to bring about any improvement in this state of things required both unity and pertinacity of action.

The spirit in which the London Society is to act seems to be suggested in the chairman's remark that they wished

“to create a public opinion” which would support public authorities in carrying out different schemes which might appear to be beneficial to London as a whole. The effort, then, seems to be to organise public opinion, and so we come round again to the subject of organisation. The President of the Royal Academy, in a letter which was read, said he thought that the Society ought to be able to give material help to the Government, or to any municipal body charged with the erection of public buildings or the laying out of new streets. So it ought; but the question remains, Do the bodies in question want to be, or will they consent to be, thus helped? It is perhaps true, as Sir Thomas Brock subsequently remarked, that in London the artistic side of a new undertaking is not considered because it is suddenly sprung upon us. There is a good deal in that; we are not naturally an artistic nation, and when an official body which propose some important public improvement are suddenly told that they have neglected the artistic side of the matter, and that their scheme is very faulty in that sense, they are surprised and hurt to hear that they are neglecting their duty; their actual feeling, if not expressed in words, probably is—“We never knew that there was any artistic side to it.” If the London Society, by creating an organised public opinion on art, can get English officials into the habit of seeing that there is an artistic side to things, they may in time effect a considerable improvement, so far as moulding taste and opinion goes. Can such a society do more than that? If they are to have public schemes submitted to them for criticism and improvement, that can only come about in one of two ways. They must either succeed in persuading the official authorities that the Society’s good opinion is so valuable, and is so much looked for by the public, that these bodies will in their own interests desire to have it and act upon it; or they must acquire some State recognition which will render it incumbent on official bodies to submit their schemes for the approval of the Society. The latter alternative is not a probable one; it might be better if it were. Whether the first-named condition may be brought about will depend a good deal on the constitution and membership of the Executive Committee.

One obstacle which there may be to the discussion and criticism of improvement schemes in advance was let out, with rather amusing *naïveté*, by one of the last speakers in the discussion, a member of the Improvements Committee of the London County Council, who said that the Committee did not like to say much about intended schemes, for fear of its effect in putting up the values of property which might have to be acquired. So there we come round again to utilitarianism.

The Picturesqueness of Bridges.

CONSIDERING that the last meeting of the Architectural Association was a joint meeting of the Association and of the Society of Engineers, the members of the latter society must have felt rather left outside by Mr. Waterhouse’s paper on “Bridges.” There was nothing in the paper treating of bridges from the modern engineer’s point of view, which is almost entirely a structural one. Mr. Waterhouse spoke mainly of the charm of various ancient stone bridges; bridges mostly of many arches, such as no engineer would be allowed by a river authority to build now, the modern requirement being to have as few piers as possible to interfere with the waterway. Most of these ancient bridges had rather heavy gradients, which are also forbidden to the modern bridge-builder. The engineer who undertakes a bridge nowadays in any place where there are official authorities (generally two different ones) controlling the bridge and its approaches, and controlling the river and its traffic, is rather squeezed between two contradictory requirements. On the one hand, he must not approach the bridge, or rise from the bank to the crown of the bridge, by more than a certain limited gradient; on the other hand, the river authority will demand from him a certain minimum of headway

above the water-level. Between these two demands the thickness of the bridge at the crown becomes also reduced to a minimum, and that is one of the arguments—always a strong and sometimes an unanswerable one—used by engineers to justify the preference for a steel span in place of a stone or granite arch. The conflicting requirements, they urge, cannot be satisfied by any other means; and though this argument may sometimes be rather speciously used, there are no doubt cases in which it is no more than the truth.

There can be no manner of doubt, however, that the ancient stone bridge of many arches was, in the picturesque sense, the most beautiful kind of bridge ever built; and it was a real pleasure to see so many examples of these structures put before us in the lantern enlargements from many of the late Mr. Alfred Waterhouse’s beautiful sketches, which were the chief illustrations used. These old stone bridges, with their broad surfaces and perspective of arches, seem to form a part of the landscape; they cannot be removed from a scene without altering its character and in general spoiling it. If we are not allowed by modern legislation to erect new bridges in this form, let us at least try to preserve those that now exist, and not assent too hastily to assertions that this or that old stone bridge, on account of its gradient or its insufficient width, is inadequate for its modern uses. Often these assertions are made very lightly, by official bodies who want to be doing something which can be called a public improvement. Often the alleged inconvenience is a very slight one, not in the least worth spoiling a beautiful scene on account of it. Especially should we endeavour to preserve the more important masonry bridges over the Thames in the neighbourhood of London; structures which combine picturesqueness with (as Mr. Waterhouse said of Richmond Bridge) a certain dignity of design that reminds us of the neighbourhood of a great city. Many, too, of the small single-span road bridges in country districts seem an integral part of the landscape, and it is not worth while to remove them merely because they show a slight crest which the wheeled traffic has to overtop. To pull down one of these and substitute a steel bridge, as has been done in some cases, is to lose a beautiful feature in the scene in order to avoid a very slight inconvenience. One eminent engineer, Mr. Francis Fox, whose name deserves to be mentioned with honour in this connection, is so convinced of this that he has saved many old country bridges from destruction by obtaining permission to repair them by his system of pumping liquid cement grouting into their joints, thereby rendering them stronger than ever, in spite of an outward appearance of dilapidation.

But this kind of feeling among engineers is, I fear, exceptional. Most engineers, when called upon to construct a bridge, wish to make it with steel spans, even if they give way so far as to admit masonry piers. It is the practical view, and we believe a perfectly sincere one, that this is the best and most workmanlike manner of doing it; and, as we have admitted, there are cases in which the official requirements cannot be met in any other way. We have had some fine examples of granite bridges lately, notably the one at Putney, which, though plain, is in every respect excellent, and supersedes an exceedingly picturesque old timber structure which was undoubtedly dangerous to the river traffic, especially in strong tides, and it was gratifying to find that, in spite of considerable engineering opposition, the new Kew Bridge was finally ordered to be built of stone; but in this case the choice of material was the only satisfaction; the detail is coarse and commonplace, far inferior to that of the old bridge which it succeeds. It is not very easy to understand why it is that these eighteenth-century stone bridges, though they were certainly not built by people who called themselves architects or were so by education, show such refinement of detail, while the stone and granite bridges built by engineers of the present day are seldom satisfactory in this respect. There seems to have been a certain feeling for refinement in masonry detail in those days which has evaporated now. The former Kew Bridge

with its comparatively narrow arches, was an inconvenience and even, in strong tides, a danger to boats; but it was charming to look at, and the present one is not.

A steel girder bridge may be unobjectionable in point of taste—what generally spoils it is the attempt to make it what is called “ornamental”—but there cannot be any pretence that it can ever be as fine an object as a masonry bridge. It is, in fact, objectionable in this sense either in the country or in a city. In the country it shows a manufactured and painted material which is quite out of harmony with the landscape; in a city it shows thin lines which are out of harmony with the architecture on either bank, while the masonry bridge has the fine effect of carrying the city architecture on to and across the river. It would be a great loss to London if we are to have no more such bridges in the city and in the country neighbouring on London. Is such a loss really necessary? We suggest that the requirements by river authorities are sometimes excessive, and might be relaxed with advantage. Such authorities seem to think of nothing but demanding a minimum of piers in the water-way; a demand which is sometimes much in excess of the real necessities of the case. It was this demand in the case of Vauxhall Bridge which rendered it, according to the engineer (who was very likely right so far), imperative to have steel spans. The demand was really absurd; one pier more in the river would have been no obstruction to the river traffic, which, in fact, amounts to nothing more than a few barges and an occasional small steamer. There is not much more at Lambeth, yet we are threatened with a steel bridge at that point under the same pretext, which is quite an exaggeration of the real requirements of the case. And one special reason for having a monumental bridge at Lambeth is that there is some likelihood that, in the future development of London street improvements, the passage over Lambeth Bridge may become a main route from Victoria Station to east London. And there is another thing to be said for the masonry bridge, especially if of granite, that it is likely to last much longer, and does not require painting, and upkeep, and repairs, as the steel one does. The latter is an economy at the outset; but it is questionable whether in the long run the economy is not the other way.

The subject of the treatment of bridges as streets has been mooted of late; and the idea might be welcomed for one reason, that it would absolutely necessitate masonry bridges. But otherwise there is not so much to be said for or against the idea, where, as in London and in most large cities with a river flowing through them, there must necessarily be a considerable number of bridges; the erection of houses on all of them would very much check that circulation of air up and down the river which must be beneficial to the health of the city. It is argued that people would be so glad to be able to cross the bridges, in wintry weather, without being exposed to the weather on the open bridge. We should think there were few who would not prefer the view of the river instead of being still in the midst of a street while crossing it. For London in particular, look at the fine views of St. Paul's in one direction, and the Houses of Parliament in the other, which we get from a bridge looking up or down the river. We should lose all that; we should lose half the spectacular beauty of London.

Some remarks were made at the Association meeting in regard to the beauty of suspension bridges, rather in an accent of defence, as if it were surprising to find that they always looked well. There is nothing surprising in it at all; the suspension chains represent a curve formed by the operation of natural equilibrium, and curves which are formed by the forces of nature are nearly always satisfactory to the eye. A suspension bridge can hardly help looking well; but except on a small scale it is not a practical form of bridge, being too much affected by moving loads. The suspension bridge at Clifton is a beautiful object spanning the picturesque gorge of the Avon, but there is a nice up that vehicles must keep to a walking pace over it; and that will hardly do where there is any important amount of traffic.

The question was raised at the meeting, not unnaturally, who was to be considered the leading mind in the case where an engineer and an architect were jointly commissioned to undertake the design of a bridge? There can be no doubt that the engineer takes the lead; a bridge is primarily an engineering construction, and the engineer is responsible for all that is under water; that is, for the foundations on which the bridge depends for its very existence. But engineer and architect should be appointed from the first, and should work together. To bring in an architect, after the engineering design is settled, to put architecture on to it, as it were, would be taking quite a wrong view of the functions both of architecture and of the architect. The whole design should be considered together by the two, working as collaborators. It is an idea that can hardly be said to have obtained recognition hitherto either in England or, as far as we know, elsewhere; but there is nothing in reason against it. It is only what is done in France, in the case of every public statue, where an architect is always appointed together with the sculptor to undertake the architectural details of the pedestal. An arrangement which works well with sculptor and architect is surely not out of the question in the case of engineer and architect. It ought to be a recognised practice in all cases of bridge design.

Royal Academy Lectures.

IN his third lecture on architectural drawing and illustration at the Royal Academy, on the 12th, Professor Blomfield spoke of the French draughtsmen of the seventeenth century, with special mention of the work of Lepautre, whose grand style of drawing was illustrated by a good many examples. In his concluding lecture on Thursday he took for his subject the Italian draughtsmen of the eighteenth century, and Piranesi, but the work of the latter was the main subject of the lecture, Piranesi being an artist who stands quite apart from other draughtsmen of the period, as perhaps the greatest genius who has ever devoted himself to the illustration of architecture. His industry, and the immense amount of work which he accomplished, were as remarkable as the grandeur of his style. It had been said that he worked direct on to the copper in his etchings, but this was at all events not always the case, as the lecturer had found drawings by him in the British Museum which had evidently been made in preparation for some of the etchings. Professor Blomfield referred to the extraordinary set of drawings called the “*Carceri d'Invenzione*”—“dream prisons” it might be translated—in which, as he pointed out, Piranesi had entirely quitted his usual darkly shaded and heavily worked style, and his needle seems to have been rushed over the plate in a kind of frenzy of inspiration, in the hurry to get his idea into shape. There is an element of something approaching to insanity in this set of plates, extraordinary and imaginative as they are. Other plates in his more usual manner were shown, but we should have liked to see more of the examples of his solidly drawn purely architectural subjects, such as his view looking into the Pantheon from the portico. But Professor Blomfield did full justice, in the literary portion of his lecture, to Piranesi's extraordinary genius.

The Late Mr. T. M. Rickman.

THE death, at the age of 84, of Mr. T. M. Rickman, removes from us one who may be said to be the last link connecting us with the early Gothic revival. His father, Thomas Rickman, F.S.A. (1776–1841), published in 1817 the first real text-book of Gothic architecture, under the title “*An Attempt to Discriminate the Styles of English Architecture*.” It is out of date now, of course, but for its day it was a remarkable piece of architectural analysis, and laid the foundation of the division of Gothic architecture into recognised styles; and his nomenclature for the styles is still partially in use. He built a good many churches,

which show curious evidence of the manner in which Gothic architecture was regarded in the earliest period of the revival, when it was considered sufficient to copy the details in any material, regardless of the real structure of Gothic architecture. We remember one church of his, probably still existing, in which the aisles were ceiled with an imitation in plaster of the lines of a fan vault, but reduced to a flat surface. But he was a pioneer in the Gothic revival movement, and "Rickman's Gothic Architecture" was for many years a recognised text-book. His son, the late Mr. T. M. Rickman, practised chiefly, we believe, as a quantity surveyor, but he had many interests outside of his profession, and was a very pleasant and interesting person in conversation.

The Late M. Mathurin-Moreau.

WE regret to announce the death of this very eminent French sculptor, who may be said, however, to belong rather to the last than to the present generation of French artists, having died at the age of 91. His works are not so numerous as those of some of his French contemporaries in sculpture, but he produced one group, "Les Exilés," which may be said to be one of the finest combinations of pathos of expression and power of modelling which modern sculpture has created. The "Exilés" are two, an old man, his head bowed down with a powerful expression of indignation, his heavily draped figure contrasted with the nude figure of his son, who endeavours to console him. The group is now in the Tuileries Gardens; hardly the place for it; it should hold a place of honour in some important art-museum. All Mathurin-Moreau's work is that of a gifted artist who took his art seriously, and nothing that he did but was careful and refined in execution; but "Les Exilés" is one of those rare works of sculpture which may be said to have a kind of moral grandeur of expression, and will always remain his best monument.

Anglo-Indian Ideas of Architectural Competition.

A CORRESPONDENT sends in a copy of an advertisement which has appeared in the Indian paper "The Pioneer," published at Allahabad. It states that plans and estimates are required for the erection of the Indian Officers' Club and Boarding House at Jhelum; "a prize of Rs. 100 is offered for that selected." Nothing is said in the advertisement about any further advantage to the author of the best design, as to being employed to carry out the building, etc. One hundred rupees, at the present rate of exchange, is about £6 10s.; and it is for this sum that the Deputy-Commissioner of Jhelum expects to get the best design and plan for an Indian Officers' Club. To whom is such an advertisement supposed to be addressed? To the native builders, one would imagine.

The Position of the Architect.

IN our issue for January 24th, we drew attention to a few points in the important report of a Committee on Education of the American Institute of Architects. There are two other points worth notice in that Report. One is the decisive opinion expressed in regard to the question of "State licensing *versus* Institute licensing," that "in the opinion of this Committee a man should be tried, tested, and admitted to practice by his peers—that is, the American Institute of Architects—precisely as a lawyer is admitted to the bar by his peers." The other point is the very strangely expressed opinion as to "the lack of knowledge of the most rudimentary architectural ideas, and a corresponding contempt and disregard therefore, exhibited by many engineers." We know something of that, too, in this country, though there is a slowly growing perception among the public, of late years, that engineers cannot be safely entrusted with the architectural treatment of important constructions, such as bridges. And the American Report sums up the matter

by saying that the training of an architect gives him a singularly broad and comprehensive vision, while that of the engineer is so "intensive" that it frequently produces "mere narrow-minded specialists." To put it shortly, architects understand a great deal more about engineering than engineers do about architecture, only one can never get the engineers to see that; they think that architectural design can be produced by the light of nature, without any special study.

Modern Construction.

IN the present issue we publish two articles of architectural and constructional interest dealing with the design and erection of two modern buildings, both notable of their kind, though differing entirely in spirit and character—Liverpool Cathedral and the new Whiteley's. And we would take this occasion to remind readers that we are always ready to consider contributions of this nature. We have our own sources of information and means for keeping in touch with what is going on in the building trades and in the architectural profession throughout the country, but it may very well happen that some building of interest is erected without our having heard of it, more particularly if it is a private building of which no information is furnished through the ordinary newspaper channels. We shall be very glad, therefore, if readers in any part of the country will communicate with us in the event of their being able to direct our attention to some notable new work of construction which has hitherto passed unrecorded. Modern buildings, indeed, merit the closest study, for they embody solutions of the problems that we have to face to-day: whereas old buildings, having been erected under totally different conditions, are often barren of value except from the standpoint of design.

Two Picture Exhibitions.

AT the Leicester Galleries there is a small collection of water-colour paintings of Indian architecture by Mr. Reginald Barratt, whose beautiful work in illustration of the architecture of Venice and of India is familiar to all frequenters of the Gallery of the Society of Painters in Water Colours. Some of the works here have been exhibited there; among those which we do not remember is a large and very fine drawing of the fort of Gwalior, one of the finest pieces of architecture to be found in India. There is a beautiful drawing of the Taj Mahal also. Mr. Barratt is one of the few painters who can treat architecture with thorough knowledge and appreciation of detail, and yet preserve a perfectly balanced pictorial effect. At the same Gallery is a collection of water-colours by Mr. A. W. Rich, who has advanced greatly in his art since his first rather crude contributions to the New English Art Club. Many of these, slight and broad in execution, contain very fine landscape effects. Mr. Claude Shepperson's exhibition also at this Gallery, though including a certain amount of rather trivial and sometimes grotesque work, contains plenty of evidence of brilliant talent, though it seems rather thrown away on some of his subjects.

At the Gallery of the Society of Fine Arts there is a collection of water-colours of garden scenes by Mr. G. S. Elgood who has established a reputation in the painting of this kind of scenery, especially of old-fashioned gardens with clipped trees. His work is as good as ever, but there seems perhaps a little sameness about it. What interested us more, at the Fine Art Society, was a collection of pieces of old stained glass, the property of a collector who now wishes to dispose of them. They are not on view in the exhibition galleries, but arrangements have been made for showing them properly, by transmitted light, to anyone who wishes to inspect them with a view to purchase. There is a chance for those who wish to secure a panel or two of old glass for their houses. There is one splendid bit of English glass, said to have come from Salisbury Cathedral; and there are good curious and interesting bits of old foreign glass, besides other English examples.

ON THE NEED FOR AN ENGLISH SCHOOL OF ARCHITECTURE.

Professor Simpson's Views on the new R.I.B.A. Scheme.

TO the opinions of Professor Reilly, of Liverpool, on the need for an English school of architecture, and the possible effect of the new problems in design set for the Final Examination of the Royal Institute of British Architects (as published in our issue for January 31st), we may add the following opinions of Professor F. M. Simpson, F.R.I.B.A., of University College, London. In the course of an interview with a representative of this Journal, Professor Simpson said:—

"The scheme undoubtedly has good points, but I think it also has defects. I understand that the matter is to be reconsidered before next session, so I do not wish to enter into detail now, but the two chief defects to my mind are—(1) The subjects are not 'set' as I understand the word. Little more is given than the titles of subjects, so that the picture which Professor Reilly draws of the meeting of two students working on these designs would hardly be possible under the present syllabus. It is more likely that after a few minutes' conversation one would say to the other, 'Oh! but my problem is altogether different from yours; my site is different, my aspects are different, my accommodation is not the same. Good-bye.' (2) The second defect, it seems to me, is the impossibility of maintaining a standard if designs are to be 'approved' (which presumably means certified as reaching a certain standard) by local societies. These societies are not in touch with one another, and, in the majority of cases, their members have had little experience in judging students' drawings."

Asked whether he thought it possible to examine a student in architectural design, and, if so, how, Professor Simpson said: "This, of course, is a very old question, and one which has not yet been satisfactorily answered. The Institute ask for four approved designs as Testimonies of Study, and, in addition, set a subject and give the student three days in which to work it out. The first day is for the sketch, and two whole days—a liberal allowance!—for its elaboration. These three days are either too much or too little. If there must be a 'scramble,' which I deny, let it remain a short and merry one. The solution suggested by me more than twenty years ago is, I still think, the right one. At that time there were no schools of architecture in England, and the Association were considering a day scheme of education, which, unfortunately, was not carried through. In an article which I wrote four years before being appointed to the Chair of Architecture at Liverpool, and which appeared in 'A.A. Notes' for April, 1890, my views on design were thus expressed:—'I do not think I am at all singular in holding that it is impossible to examine a man in architecture. By examination you can find out, perhaps, what practical knowledge he has, what his acquaintance is with the history of architecture, but that is all. It is only in his designs that he can show whether or not he is a good architect. The Institute gives one day to the design; a week would be none too much. Many a man can make a pretty enough drawing to $\frac{1}{8}$ in. scale who comes utterly to grief over the $\frac{1}{2}$ in. and full-size details. As I said before, I do not think you can examine a man in architecture. To do so you would have to shut him up for two or three months, and let him make designs; and that is impossible. The next best test, it seems to me, is the work done by students during an entire year from subjects set by visitors or masters. The Institute, of course, cannot manage that now; but if the suggested education scheme comes into force, then it can be managed, and that one of the chief reasons, in my opinion, for supporting the change.'"

"How, then, do you think the suggestion you make could work out?"

"In the following way:—

"(1) Design should be kept quite apart from the Final paper examination, and the existing scramble should be deleted altogether.

"(2) Four designs, as suggested, should continue to be set every year (alternatives permissible) by the Board of Architectural Education, but in consultation with the heads of the different architectural schools throughout England (if possible Great Britain). This consultation is, in my opinion, essential for success, and would help greatly in bringing the schools into touch with one another, and also into touch with the Board of Architectural Education.

"(3) Students should prepare their sketch designs unaided outside the school (or inside under restrictions), and should hand them in to the master of the school, who would retain, date, and initial them; the students keeping tracings.

"(4) In due course *both designs and sketch designs* should be submitted to the Board of Architectural Education and marked, and, according to the marks, students should be accepted or rejected.

"(5) The number of designs to be submitted might remain at four—or be increased to six if desired—and any design executed in its proper order during the three years previous to sending in should be eligible.

"If some such scheme were adopted, the design made within the walls of the Institute would disappear. The original sketch design submitted with each finished design, with the master's initials or signature on it, would be the guarantee that the work was the student's own.

"Instead of sending in such designs as Testimonies of Study before the paper examination, I think a far preferable course would be that they should be submitted *after* a student had passed that examination. Design is the crown of a student's career. A student must possess practical knowledge before he is allowed to practise, and the profession owe it to the public that this safeguard is provided; otherwise men will obtain their knowledge at the expense of the public. Students could, of course, try their 'prentice hand' at design during their early years of training, but let the problems set them be such as they can understand. When they are too difficult the master makes the design, and the student merely has an exercise in draughtsmanship. Another advantage in placing the design last is, that the Testimonies of Study required before the paper examination might consist entirely of measured work. Such work has, I believe, been cut out before the Final now."

Asked how he thought such a scheme would affect provincial students, Professor Simpson said: "Advantageously, I think. There are very few towns of importance in which architectural classes of some sort do not exist, at which students can work, and it would be an additional inducement to the towns not possessing them to start such classes. Moreover, students in the country or in small towns would, to a greater extent than is the case at present, be led to regard a year or two spent at a school in London or some other large centre as an essential part of their architectural training."

"What other defects in the new Institute scheme do you see?"

"The chief blot is the retention of the Preliminary examination unaltered. That has for long been admitted to be insufficient by everyone who has experience of students. Yet it remains as before. The new regulations pile up weight on top and leave the foundations insecure. Of all people, one would have thought architects would have been the last to make such a mistake."

"Do you think that all schools should aim at an ideal?"

"By all means have an ideal, and let it be as high as possible, but—and this is the important thing—let it also be broad; especially at the base."

THE ERECTION OF LIVERPOOL CATHEDRAL.

BY ARTHUR GREEN.

(Concluded from p. 146, No. 890.)

THE Lady Chapel, the first part of the Cathedral scheme completed, is a lofty building, being 58 ft. from the floor to the apex of the vaulting; it is 100 ft. long by 35 ft. 6 in. wide, including the gangways at each side; the width between the inner walls that carry the vaulting shafts being 25 ft. The floor of the Lady Chapel is 13 ft. 7 in. below the floor of the Cathedral. At the west end, the narthex is divided from the Lady Chapel by a wide low arch, which carries the west gallery, the gallery being at the same level as the floor of the Cathedral. An archway on the gallery gives access on the north side to the south aisle of the choir, and on the south side to the upper porch. A spiral staircase, commencing on the same level, leads to the organ and to the walking-way in the choir aisle walls, continuing upward to the floor over the organ. At this point begins the walking-way which crosses the building on the outside at the foot of the great east window, and continues across a bridge to the walking-way round the top of the chapter-house. Above the wide arch of the narthex are two piers, with three arches, carrying the organ floor. The front of the organ gallery, which projects 3 ft. 6 in., is carried on a large English oak beam 26 ft. long, its entire length being beautifully carved into foliage and shields. Above the beam are panels, with a carved capping. A low arcade of six arches on each side of the Lady Chapel carries the triforium gallery.

The piers of the arcade are quite plain, and are without caps; they stand on a moulded base, with vaulting shaft attached. The arches are fully moulded, the moulding dying into the splay of the piers. Behind the piers is a narrow gangway. Above the arches is a deep string, which runs all round the chapel, on which are carved the words from St. John iii., 16, 17: "For God so loved the world," etc. Between the words are sprays of foliage.

The carved string forms the base of the stone screens in the front of the triforium gallery. The screens are 11 ft. high, and are divided into five bays each by mullions, and having tracery heads with carved cusps. Over the tracery is a moulded cornice. Projecting from the cornice are winged figures, three in each bay, some playing on ancient instruments, whilst others are singing. Above the cornice, and completing the screens, is a deep band of cresting, richly carved into lilies, rose, shamrock, and thistle alternately. The windows on the north and south sides of the chapel are of two lights, 2 ft. 11 in. each, the sill being 22 ft. from the floor; the height of the jambs from sill to tracery being 22 ft. There are six windows on the south, and five on the north side. In the apse there are three three-light windows of similar dimensions to the side windows. All the windows are filled with painted glass from the studio of James Powell and Sons, Whitefriars. In the lower panels of the central apse

window is the stem of the Tree of Life the branches of which spread through the whole of the windows on each side of the chapel. The tree is full of life, there being numerous children, birds, and animals indicated amongst the branches. The central window of the apse contains the adoration of the Magi. In the tracery above is the figure of Eve in adoration. The upper panels of the left-hand apse window have three single figures—Hannah, Ruth, and Sarah. In the lower panels of the window is the scene of the Annunciation, the figure of Eve being tempted in the tracery above. In the upper panels of the right-hand window of the apse there are three single figures—St. Elizabeth, "mother of St. John the Baptist," Ann the prophetess, and Mary of Bethany. In the lower panels of the window is the Presentation in the Temple. The tracery contains the figure of Eve as the first Mother. The windows on the north side of the chapel are all single figures, representing historical saints. No. 1 window, counting from the apse, contains Queen Bertha of England and Queen Margaret of Scotland; No. 2 St. Bride of Ireland and St. Noy of Wales; No. 3, St. Helena and St. Hilda; No. 4, St. Bega and St. Werburga; No. 5, St. Frideswide and St. Osburga. In the windows on the south side of the chapel are single figures, which represent Prayer Book saints—No. 6, counting from the apse, St. Anne, Mother of the Virgin Mary, and St. Mary Magdalene; No. 7, St. Perpetua and St. Cecilia; No. 8, St. Agatha and St. Prisca; No. 9, St. Catherine and St. Lucy; No. 10, St. Agnes and St. Faith; No. 11, St. Margaret of Antioch and St. Etheldreda.

DETAIL OF CARVED CRESTING, ETC., IN LADY CHAPEL, LIVERPOOL CATHEDRAL. G. GILBERT SCOTT, ARCHITECT.

BAY OF SANCTUARY, LADY CHAPEL, LIVERPOOL CATHEDRAL. G. GILBERT SCOTT, ARCHITECT.

On entering the narthex from the porch of the chapel, immediately on the left is the atrium, in which there are three two-light square-headed tracery windows. The glass in these windows was given by the Girls' Friendly Society, and commemorates notable women of modern times, the following portraits being included: Juliana of Norwich, Susanna Wesley, Elizabeth Fry, Josephine Butler, Charlotte Stanley Countess of Derby, Queen Victoria, Angela Burdett-Coutts, Catherine

Gladstone, Christina Rossetti, Elizabeth Barrett Browning, Lady Margaret Beaufort, and Ann Clough. On the stairs from the narthex to the Lady Chapel gallery is a two-light tracery window, the glass of which also is the gift of the Girls' Friendly Society, and contains portraits of the following notable women: Margaret Godolphin, Mother Cecile, Louisa Stewart, Dr. Alice Marvel, Ann Hinderer, Grace Darling, Kitty Wilkinson, Agnes Jones, and Mary

Rogers. The scheme of the glass is good, and fitting for a Lady Chapel, as it comprises Bible women, Prayer Book and historical saints, and modern noble women.

The triptych at the east end of the chapel is of painted and gilded wood, richly canopied. The upper panels represent the Nativity, the lower panels the Baptism of our Lord. The scheme of decoration is in blue and gold. Rich hangings at the sides, also blue and gold,

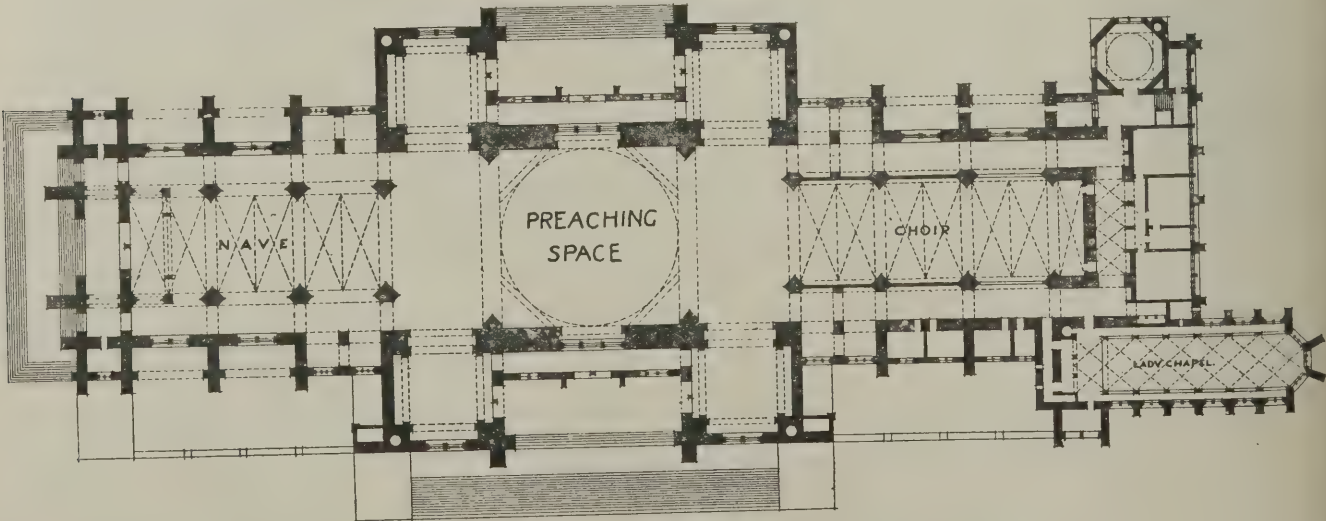

LIVERPOOL CATHEDRAL: AMBULATORY VAULTING.

and the Holy Table, with its beautiful white frontal, give the whole a very striking effect. The ceiling is a barrel vault, springing at a height of 44 ft. from the floor, with transverse and diagonal ribs; carved bosses are placed at each intersection of the ribs. Towards the apex of the vault, a smaller rib is introduced, forming panels, and producing a very rich effect. The curves on the smaller ribs become very interesting where a segment of a circle crosses a segment of a circle. Interest is given to the vault by its being cut for the heads of the windows. At the west end is the organ, a splendid instrument by Willis. The organ case is of oak, beautifully carved, and reaching up to the vaulting. Two angels at each side hold trumpets. At the level of the organ gallery are two large angels, carved in stone, holding shields. On the face of the shields are sprays of lilies. Mr. J. Phillips executed the whole of the wood and

stone carving, with the exception of the triptych, which was done by Messrs. Rattee and Kett, of Cambridge. The floor of the chapel is composed of large slabs of Alpine green and seconds statuary marble, laid in courses with random lengths; across the chapel at each vaulting shaft are panels of inlaid black and white marble. The steps to the altar are in various lengths of black and white marble, alternated. The bishops' and canons' stalls, choir stalls, lectern, faldstool, etc., are of English oak and richly carved. All the doors also are of English oak. The iron-work on the doors is by Bainbridge Reynolds. Over the doorway leading to the lower vestries is a carved crown, with the word "Alleluia." On the jambs are shields and Tudor roses. The chapel is lighted by six gilded pendants, hanging by chains from the vaulting. These were executed by Bainbridge Reynolds, and play a considerable part in the decoration

of the chapel. The entrance to the Lady Chapel is from St. James's Road, through a two-storey porch, the lower porch having a wide arch at the entrance. The ceiling is a barrel, divided into panels by ribs. At the apex are carved bosses, and there is a cresting on each side of the ridge rib. The double doors on the inner wall of the porch are English oak, richly carved. The upper porch, the floor of which is on a level with the chapel gallery, is approached by a flight of stone steps. The entrance is on the west side. A doorway opens on to the chapel gallery. The front of the upper porch is divided by a slender stone pier and two arches. There are four figures with canopies, the two figures on the pier representing Samuel with the lamp, and Timothy with the Bible. On the two buttresses are David with the sling, and the boy with the loaves and fishes. In the gable above is a representation of the Good Shepherd, with boy and girl. The roof of the porch is of English oak, covered with grey stone slates. The roof of the Lady Chapel is of English oak covered with copper. The chapel is heated by hot water, radiators being placed both in the floor and in the triforium gallery. The heating engineers are Messrs. Haden and Sons. Outside, the chapel is rather severe, having a series of lofty buttresses, the space between the buttresses being 11 ft. 3 in., which is entirely filled with the windows. The jambs of the windows are a plain splay, from which the deep mouldings of the arch spring. The buttresses rise out of a deep weathered base. A walking-way with tracery balustrade goes round the chapel, 2 ft. above triforium gallery level, from which access is obtained. The buttresses are tunnelled for a walking-way. Above the windows, and on a level with the floor over the organ, is a corbelled-out walking-way, with balustrade. The tops of the buttresses finish with a weathered gable. On the face of the buttresses are carved shields, and lead water shoots, which connect with the gutter behind the parapet, are provided, for the water to get away in the event of the gutters being blocked. All the rainwater heads and down pipes are of cast lead, the heads being ornamented. The Lady Chapel, which is mainly the gift of the Earle and Langton families, was consecrated by the Archbishop of York on June 29th, 1910.

PLAN OF LIVERPOOL CATHEDRAL.

CORRESPONDENCE.

*The Influence of Competition upon
Design.*

To the Editor of THE ARCHITECTS' AND
BUILDERS' JOURNAL,

SIR.—In the interesting but perhaps somewhat inconclusive paper on "The Influence of Competition upon Design" read by Mr. J. Milton Dyer before the American Institute of Architects at Washington and reported in your issue of February 7th, p. 154, although we are told that in America a Government type of design based upon the use of the Orders is being evolved, the author hardly seems to have come to a definite decision as to what the influence in its widest sense is, or as to whether it is the good or the reverse.

Though we might take his expression of opinion, towards the end of his paper, "that the best method of securing an artistic as well as practical result is by the direct selection of an architect," as a definite condemnation of the existing systems, yet the paragraphs that follow suggest that he has hopes it will have better results in the future, and eventually exert a beneficial effect upon architecture.

Now, the subject is one of such importance to the profession and the welfare of architecture, that I think it merits further discussion; and if you are willing to place your columns at the disposal of your readers for that purpose their views may prove of interest.

If it can be shown that the influence of competitions is harmful to design, then every effort should be made to amend the conditions under which they are held.

But I hold, to the contrary, that their general effects are good, and I cannot concur with Mr. Dyer's remark that competitions do not stand for "training in design."

Restricting the scope of our consideration to affairs in our own country, and granting the author's assumption that the assessors or jury exert great influence upon the designs submitted in competitions, may we not assume, after making due allowance for the personal idiosyncrasies and wide differences of taste among the leaders of our profession, that, inasmuch as assessors are generally drawn from the most talented and cultivated section of the central professional body, open competitions produce a healthy emulation among architects, and tend greatly to raise and unify the standards of design throughout the whole country—leading eventually to the development of something approaching a national style. These results may, I think, be seen in our course of evolution at the present time. A comparison of the designs of the last ten or fifteen years, during which competitions have been numerous, with those of, say, twenty-five or thirty years ago, will prove greatly to the advantage of the former.

The additional facilities for architectural education, which have to some extent contributed to this result, are a direct response to the demands of the many brilliant young men who, seeing the chance of an early recognition of their talents, are being drawn into the profession every year.

Individual genius may suffer at the hands of professional assessors afraid to be the first to approve of innovations, or unduly influenced by the supposed necessity of sacrificing all aesthetic considerations to minor points of planning and

economy of cost, which weigh so heavily and count for so much with the members of the committee by whom the award has to be confirmed.

For the production of genius, however, a high level of general professional achievement, and a widespread culture and appreciative discernment among the public, is generally necessary.

Competitions, by the emulation provoked and publicity given to the subject, do make for the production of both these requirements, and the young man of ability and genius is encouraged to great effort, and given his first chance, so long as his innovations or eccentricities do not fall too far wide of the usual standards of design.

Moreover, the competition system makes for the more complete control of professional affairs by professional men,

which, in these days, when our public men are so unappreciative of architecture as an art (as witness the famous strictures of a First Commissioner of Works concerning Mr. Shaw's Scotland Yard buildings), is highly desirable; and at the same time it eliminates the possibility of municipal or political jobbery.

Is it not probable that exceptional talent will be as soon, and perhaps more surely, recognised by the professional assessor as under any system of private or State patronage?

The Achillean heel of the competition system, at first sight, would appear to be found in the fact that the genius, having been given his first chance, cannot develop his individuality to the full, but in competition for all future public work must play down to the limit of the assessor's appreciations and the con-

G. GILBERT SCOTT, ARCHITECT.

ditions of the competition; and that any great iconoclast or innovator—any architectural Wagner—would meet with more opposition from a professional jury than from a private connoisseur. It would seem that here was a case for beneficent and intelligent patronage of an autocrat.

But for every time that this beneficent patronage has been at hand, how often has it been missing! Under the present system, genius has a fair certainty of early support and recognition, with always a free hand in regard to detail. Revolution will be more difficult, and progress will be slower, but perhaps more sure, than under other conditions.

Coming down to the actual influence of competition upon the details of design, it is difficult to believe the use of the order is really the result of the existing system. Is it not that competitions have made necessary a fairly high standard of design, and the order has been found one of the simplest and easiest methods of producing imposing and rich effects in combination with unity and monumental dignity in buildings devoted to multifarious purposes and divided into many departments? One can sympathise deeply with Mr. Dyer's exclamation—"Must we, in competitions, be eternally condemned to the use of the order?" On the score of sincerity alone one would often like to see it eliminated. I for one should like to see architecture freed from the dead hand of tradition. But the principles and details of design are hardly likely to be completely controlled by the competition system; and fundamental changes will come about rather as the results of a great revolution in construction—the introduction of new methods and materials such as are found in the systems of reinforced concrete finding expression

in æsthetic forms that are true to and indicative of those materials and structural necessities.

H. S. FLEMING, A.R.I.B.A., P.A.S.I.
Old Charlton, S.E.

[We have printed Mr. Fleming's interesting letter in full, and are willing to admit further correspondence on so important a subject. The space that we can devote to it, however, being limited, letters must be kept as brief as possible. Otherwise they will stand but a slender chance of insertion.]

A Sheffield Improvement Scheme.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—In your notice of this scheme you state that the spaces between the skylights in the Lower Market might be rather deficient in light in dull weather.

The skylights marked A, B, C, D on section are of an aggregate width of 180 ft. in a total width of building of 350 ft., which is in excess of the recognised rule as to the proportion of skylight requisite for a picture gallery—viz., half the width of the gallery. The Lower Market also being very lofty (25 ft. floor to ceiling), the spaces, 50 ft. wide, under the solid ceilings, would be amply lighted by the skylights, 40 ft. wide on both sides, admitting rays of light to every part, the only parts dependent upon reflected light being the upper parts near the ceiling, as is also the case with respect to the solid parts of the ceiling of a picture gallery.

EDWD. M. GIBBS.

[The section referred to is the cross section in a pamphlet (presumably obtainable, price 2d., from the offices of the "Sheffield Daily Telegraph") in which the scheme is fully described and illustrated.]

LEGAL.

Falling Brick Injures Foot Passenger.

In the King's Bench Division last week, before Mr. Justice Avery, James Chapman, twenty-four years of age, sued Messrs. John Greenwood, Ltd., contractors, for damages for personal injuries caused by a brick falling upon his head from a building under construction by the defendant firm in St. John's Street Clerkenwell. It was stated that the plaintiff was on his way home to dinner on May 19th last, and while he was passing along St. John's Street a brick fell from the top of No. 423, which was being rebuilt, and struck the plaintiff on the head, causing injuries which necessitated a cessation from work for some time. Plaintiff's case, as disclosed by the evidence, was that the accident caused him to lay up for sixteen weeks, and after that his wages were reduced from 28s. a week to 6s. or 7s. Expenses were set down at £30 16s.—The defendants, who admitted liability and paid £25 into court, contended, however, that there had been no negligence on the part of the defendants' servants, and that the claim was excessive, as the plaintiff had quite recovered from his injuries. The foreman of the work said that every precaution was taken to protect the public passing along the pavement, and that the accident was only attributable to the unaccountable conduct of the brick, which, falling from the top of the house inside the building, passed through two floors, striking the joists in its passage and finally rebounding through one of the windows just above the hoarding and striking the plaintiff on the head.—The jury without leaving the box, found for the plaintiff, assessing the damages at £1,000 plus the doctors' fees, £87 12s. in all.

THE FIREPROOFING OF WHITELEY'S.

A NOTABLE EXAMPLE.

MESSRS. WILLIAM WHITELEY, Ltd., the well-known "universal providers," have had several severe experiences of destruction by fire; consequently, in the great new building which has recently been completed for them from designs by Messrs. John Belcher, R.A., and J. J. Joass, F.R.I.B.A., they decided that everything possible in the way of fire-resisting construction and fire-protection should be provided.

The accompanying illustration of the exterior of the new building (for which we are indebted to Messrs. Mather and Platt, Ltd.) shows the long front to Queen's Road, Bayswater, and the return to Porchester Gardens, the block so far erected representing about one-half of the entire rebuilding scheme, which embraces the older portion of the Queen's Road front and the return, on the north side, to Douglas Place. The new premises in themselves form a very large shop, but when the whole is completed Whiteley's may claim to be called gigantic. Such being the case, it is fortunate that the work should have been placed in capable hands; otherwise we should have to deplore a lost architectural opportunity, and we should have trusted once again on our gaze a trivial and commonplace building. As it is, Messrs. Belcher and Joass have produced, for the public, a very noble façade, while at the same time fulfilling the multitudinous and imperative requirements of a place where shopping is conducted on a very large scale. For the present, however, we are not so much concerned with the architectural features with the fire-resisting construction and equipment of the new premises.

Steelwork.

First it may be stated that the building is of steel-frame type, the total amount of steelwork being nearly 3,000 tons. The stanchions are carried down to cellars, and are enclosed by pumice rock and concrete, this protection averaging a thickness of 4 ins. The whole of the weight is taken by the steel frame, the superimposed granite columns which constitute the dignity of the exterior being only architectural dressings supported by the steel stanchions. The main entrance in Queen's Road, where the columns, arranged in pairs, are built up of solid sections, the lower columns are purely decorative, as those above are not supported by them, but are carried on a deep girder that spans 50 ft. opening here.

The same remark about the weight borne by the steelwork alone applies to the interior, the 14 in. brick walls which divide the new building into seven distinct sections being merely division walls. In this connection it may be claimed that the conditions imposed by the design in the first place have determined the necessity for the form of construction, and though the endeavour to give the frame an architectural expression must, under present conditions, solve itself into expedients that are in conformity with what may be deemed the established architectural canons, still the architect has no option in the matter, and some sort of apology is therefore called for. For example, the necessities of rapid construction, the amount of obstruction in the matter of pillars or piers, and the impossibility

of having steelwork exposed—all enforce a solution which, though not ideal, is nevertheless the best possible in the circumstances. Saving of space is one of the several claims put forward for modern steel-frame construction and similarly for reinforced concrete, in elucidation of which one need only work out the increased area of brick or stone walls in a modern office building in comparison with such construction; it will be found, possibly, that an extra office is thus provided on every floor, and the additional revenue afforded by these means will certainly be a marked return for any increase there may be in the initial cost of construction.

Whiteley's affords a good instance of this saving of space by modern construction, particularly in the vaults that extend under the pavement, these vaults having a roof of reinforced concrete ingeniously cantilevered out from the retaining wall that encloses the site.

Division Walls, Fireproof Doors, and Fire-Resisting Glazing.

The plan of the building comprises, as explained above, seven distinct sections,

in two of which are large rotundas extending up the whole height of the building—five floors—and covered at the top by glazed steel-framed domes. The cubic contents of the sections are in excess of the official requirements, amounting to more than 700,000 cubic ft. in each section, and in order to comply with the regulations the solid brick division walls are 14 ins. thick instead of the 9 ins. required where the cubic contents do not exceed the stipulated capacity. With the enclosing walls of protected steel stanchions, filled in between with windows having steel frames and fire-resisting glazing, and the interior of the building divided by thick brick walls, it became necessary, of course, to see that all openings in those walls were fitted with effective doors. Thus we find that in the main openings from one department to another are steel-framed doors with fire-resisting glazing, centrally fitted, while on either side, leaving an air-space or "fire-check" of 3 ft. between, are rolling steel shutters that can be wound up and down by a handle or closed instantly by a lever, in case of fire.

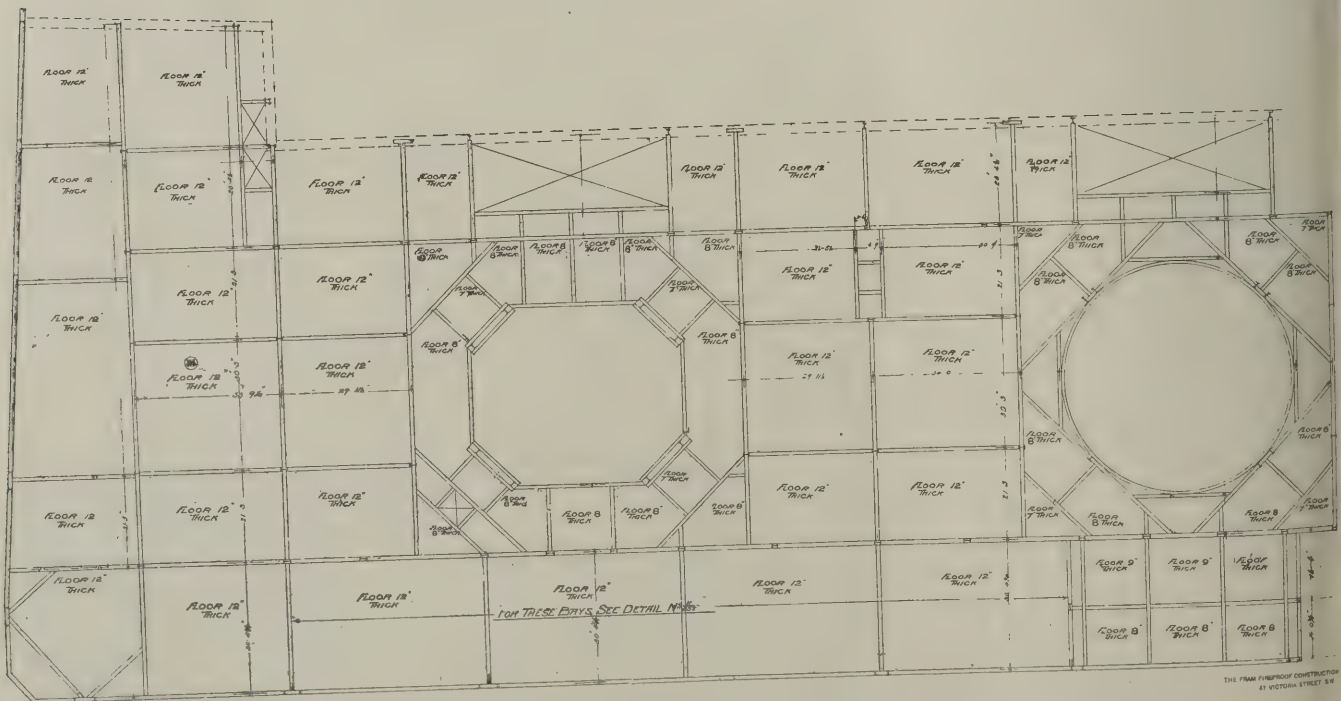

The illustration on page 201 shows one of these rolling shutters about three-parts down, the steel-framed swing doors with fire-resisting glazing being visible below. The shutters have been specially

SECTIONS OF TILE FLOOR CONSTRUCTION AT SECOND-FLOOR LEVEL.

designed and constructed for this building, and the openings are of a greater size than has been in general use before, being in all cases 12 ft. wide with a height averaging 10 ft. 6 in. The shutters are constructed of steel slats of No. 20 gauge, so interlocked with one another as to form continuous hinges that act like strengthening ribs across the entire width, rendering the shutters both fire-proof and weather-proof. The sides are fitted with locking shields and with fire stops to prevent the flames from passing round the ends of the shutters. The construction is shown by the accompanying diagram, from which it will be seen that the shutters roll up upon steel tubular drums, which are supported by steel brackets mounted upon concrete templates on the top of brick piers. On the end of the drum shafts is fitted the necessary gearing for raising and lowering the shutters, this gearing being so arranged that both shutters can be operated at the same time, and from either side of the opening; the same mechanism applying to the lever for instantly closing the shutters in the event of an outbreak. Each of the openings in which rolling shutters are fitted has a steel casing that completely surrounds the brick piers and extends through the opening, forming a steel enclosure both for the sides and for the soffit. The casing is packed inside with non-combustible material, thus obviating the necessity of using either wood or plaster lining and moulding; it is, moreover, easily removable in case of necessity, and has therefore many advantages.

The fire-resisting electro-copper glazing throughout the building has been supplied by the British Luxfer Prism Syndicate, Ltd., the steel window screens by the Pittall Manufacturing Co., Ltd., and the rolling shutters by the Wilson Rolling Shutter Co. Subsidiary openings are closed by tin doors (supplied by Messrs. Mather and Platt, Ltd.) on each side of the opening, and having an air-space or "fire-check" of 6 ft. between them. These doors have spring hinges, so as to close automatically.

Floor Construction.

The floors are of hollow clay blocks reinforced with steel rods and built up with concrete, on the system of the Fram Fireproof Construction Co., of London and Manchester. The main bays are very large in area, some being as much as 45 ft. by 30 ft. without intermediate supports, and the floor construction here averages 12 ins. thick, smaller bays being made up to the same thickness in order to preserve a level ceiling. The hollow blocks are built in the floors in several ways, according to the need, sometimes being placed side by side and in other cases alternating with blocks on end, but always with steel rods between their lower ends filled in and over with concrete, resting on T-beams. In the larger bays the reinforcement is double—crossing from side to side—and a very stiff floor is thus obtained.

The accompanying illustration shows the construction. The blocks are carefully moulded and well burnt, and are corrugated to secure cohesion with the concrete. They are used in the lower half of the floor slabs to secure lightness, sound proofness, and greater fire-resistance. The tensional stresses are taken up by the mild steel rods inserted between the blocks, these rods having a sectional area that gives a safety factor of 4 over the maximum stress arising. Shear stresses are also dealt with by the insertion of steel members of sufficient size to take them up. The compressional stresses are taken by the concrete covering, which varies in thickness according to

the spans and loads to be dealt with, and is so arranged that the concrete should never be compressed to a greater maximum load than 600 lb. to the square inch, with the same safety factor as the steel. Altogether the area of floors and roof exceeds five acres, and this extensive construction had to be carried out with the utmost rapidity.

The foregoing covers the fire-resisting construction at the new Whiteley's. The fire-protection may next be dealt with. It includes (1) a sprinkler system, (2) a fire detection and alarm system, (3) a hydrant system, and (4) a system of fire-escape staircases.

WHITELEY'S NEW PREMISES: OPENING FROM ONE DEPARTMENT TO ANOTHER FITTED WITH ROLLING SHUTTERS AND FIRE-RESISTING GLAZED DOORS.

The Sprinkler System.

This is the well-known Grinnell system, which has been arranged by the sole proprietors, Messrs. Mather and Platt, Ltd., though, owing to a strike, the work had to be handed over in an unfinished state to Messrs. H. J. Cash and Co., who completed it. In this system lines of horizontal distributing pipes are laid under the flooring (except in the basement and on the top floor, where they are hung from the ceiling) at intervals of 8 ft. to 12 ft., and are connected with larger vertical rising pipes, supplied from a source that will keep the water in the pipes under constant pressure. The automatic sprinklers are attached to each of the lines of distributing pipes. Should a fire break out in any part of the protected building, the heat at once rises to the ceiling, where the temperature very soon becomes sufficiently high to melt the solder on the link of the sprinkler (which fuses at 155 degrees Fahr.). The elastic valve in it is thus released, and the water is discharged profusely over the fire. The Grinnell sprinkler has a clear $\frac{1}{2}$ in. outlet and a deflector or splash plate, by means of which the stream of water is broken into spray and distributed effectively on the ceiling above as well as on the floor below. At a pressure of only 5 lb. per sq. in. it is claimed that this sprinkler will completely protect 100 super. feet of floor area.

In positions where water in pipes is likely to freeze, the Grinnell dry-pipe system is applied. In this system a patent differential air valve intervenes between the water supplies that are beyond the reach of the frost and the sprinkler pipes in the building. Within the pipes air under moderate pressure keeps the valve closed, thus excluding the water, but the opening of one or more sprinklers in case of fire lets the air out of the sprinkler pipes, and simultaneously the valve is automatically opened by the water, which fills the pipes and is discharged from each unsealed sprinkler.

WHITELEY'S NEW PREMISES: DETAIL VIEW ON TOP FLOOR, SHOWING SPRINKLER AND CAPITALS OF COLUMNS.

At Whiteley's the sprinkler system is divided into four separate installations, three of them being on the wet principle and one on the dry system—in the cold storage, the roofs over the despatch yard, and other outside portions of the building. In order to gain absolute security, the pipes are supplied from four distinct

sources—namely, direct from the wa main, from a large pressure tank in roof, from a hydraulic injector in basement, and from a connection with steam pump in the old buildings: whole control being in one locked room. Each installation is connected to separate alarm gong at the back of

building, and the unsealing of any sprinkler will set the corresponding gong ringing continuously.

The Grinnell sprinkler system was installed in Messrs. Whiteley's older premises, and its effectiveness is testified by the fact that whereas in the four fires which occurred between 1882 and 1887, before the sprinklers were installed, there was an average loss of £105,000 per fire, in the three which have occurred since the system was installed the average loss has been about £250 only. It is to be noted, also, that in the fire that occurred on March 14th, 1910, the sprinklers which then acted so effectively had been

erected for more than twenty-one years. The late Mr. Whiteley was, indeed, the pioneer of sprinklers in the South, his installations having been the first to be erected in London.

The domes over the rotundas (of which two views are here given) are double-glazed with wired glass, and, in addition to the sprinklers around the inside of the drum, there is a collar around the crown served from either side by 2½ in. service pipes, by which means the domes could be flooded with water in case of fire. The arrangement is also useful for cleaning purposes. The domes are 67 ft. in diameter and comprise about 40,000 super-

feet of glazing, the whole of which has been carried out by the British Challenge Glazing Co., Ltd.

The Fire Detection and Alarm System.

In addition to automatic means of fire-extinction, the new Whiteley's has a complete system of fire-detection and alarm. This is the "Aero" system, of The Aero Automatic Fire Alarm, Ltd. It comprises an installation of small-diameter copper pipe, which is run all over the building and is connected with an indication board on the ground floor. In the event of an outbreak of fire, the heat, surging to the ceiling, would cause the air in the pipe system to expand, and, by means of a

WHITELEY'S NEW PREMISES: VIEWS OF DOMES OVER ROTUNDAS IN COURSE OF ERECTION AND AS COMPLETED.

sensitive diaphragm, would not only set alarms ringing at different points in the building itself, but also in the company's offices in Queen Victoria Street; while a pointer on the indication board on the ground floor would show exactly where the fire was; so that there would be the least possible delay and confusion in locating and then extinguishing an outbreak.

The Hydrant System.

As a further protection, and in addition to the sprinklers installed throughout, there is a hydrant system, comprising large rising mains with hydrants and pipe lengths connected ready for use on every floor. There is nothing novel about this system, but it is one further means of doing everything that can be conceived in the way of the prompt extinction of any outbreak of fire that might occur. Messrs. Mather and Platt, Ltd., have installed the hydrant system.

Fire-escape Staircases.

Finally, there are the fire-escape staircases and balconies, supplied by the St. Pancras Ironwork Co. Access to these is gained from every floor, and there is thus provided abundant means of escape in case of fire. In connection with these staircases a rather interesting question arose regarding the obstruction of light, and as the architects were anxious that the windows should not be darkened more than was necessary, the company's patent renewable reinforced concrete treads (which had been originally specified for all the stairs) were replaced by perforated iron treads and risers, made to meet the ordinary requirements of the London County Council, the concrete treads being used in one staircase only where light was not important, and in small portions of the other stairs where the conditions rendered a non-slippery tread specially advisable.

Two interior photographs of the new Whiteley's are here reproduced, in both of which will be noticed the twin columns that are so effective a feature of the rotundas. There are 72 of these. They are of "Siena" scagliola marble enclosing a steel and concrete core, and were executed by Messrs. Bellman, Ivey and Carter, Ltd., who also carried out the enriched capitals and moulded bases, which are bronzed with pure copper by a special process.

The general contractors for the new Whiteley's were Messrs. Holloway Brothers (London), Ltd., the steelwork having been carried out by Messrs. Dorman, Long and Co. (steel-frame structure for external lifts and steelwork for roof over despatch yard by Messrs. Powers and Deane's Ransome's, Ltd.).

The inside staircases, all of steel, were erected by the Crittall Manufacturing Co., Ltd., who also supplied steel doors for certain openings.

Messrs. Henry Hope and Sons, Ltd., supplied bronze swing doors (with fire-resisting glazing) on the ground and first floors.

All the constructional steel and reinforced concrete was designed by, and the engineering work described above was carried out under the direction of, the consulting engineer, Mr. Alexander Drew, of 64, Victoria Street, S.W.

Appointment.

Mr. Herbert Phillips Fletcher, F.R.I.B.A., F.S.J., A.M.I.C.E., of Messrs. Banister Fletcher and Sons, 29, New Bridge Street, Ludgate Circus, E.C., has been elected by the Blackheath Bench of Magistrates as their advisory architect.

COMPETITIONS.

Mural Designs Competition.

The Committee, of which Mr. D. S. MacColl is chairman and Mr. Charles Aitken and Mr. Wilfrid Walter are joint hon. secretaries, formed to promote the practice of mural painting in schools, churches, hospitals, and other public institutions, more especially by young artists and students, a scheme long ago propounded by Mr. Watts, will hold a competitive exhibition of designs at Crosby Hall, Chelsea, in the latter part of May. Several schools and other buildings have already offered wall-spaces for experimental treatment, and designs from the exhibition will be selected to be carried out in these spaces. It is believed that students and young artists will welcome the opportunity of practice in the art of large decorative painting for the sake of the training thus obtained; but the Committee invite subscriptions towards a fund for giving chosen painters a modest remuneration. They will also welcome further offers of wall-spaces in schools and other buildings. The Hon. Treasurer is Mr. John Ross, C.A., at Crosby Hall, Cheyne Walk, Chelsea, and information may be obtained from the hon. secretaries at the same address.

Society of Engineers Status Prize.

The Council of the Society of Engineers (Incorporated) offer two premiums of books or instruments to the value of £8 8s. and £4 4s., as first and second prizes respectively, for approved essays on the subject of "How to improve the Status of Engineers and Engineering, with special reference to Consulting Engineers." The Council reserve the right to withhold either or both the premiums if the essays received are not of the required standard of merit. The competition is open to all, but application for detailed particulars should be made to the Secretary, 17, Victoria Street, Westminster, before entering. The last date for receiving essays is Friday, May 31st, 1912.

Proposed New Church of St. Luke, West Hartlepool.

The limited competition for the above, in which Mr. W. D. Caroe acted as assessor, has resulted in favour of the design submitted by Messrs. Lofting and Cooper, of 44, Bedford Row, W.C.

LIST OF COMPETITIONS OPEN.

FEBRUARY 27TH. WORKMEN'S COTTAGES, THEDWASTRE, SUFFOLK.—Thedwastre R.D.C. invite plans and estimated cost for the erection, in pairs, of workmen's cottages in their district. The advertisement is headed "To builders and contractors." Plans to be sent to Henry E. Wilkes, Clerk to the Council, Stowmarket.

MARCH 15TH. LAYING OUT ESTATE, PRESTATYN.—Designs for laying-out the Prestatyn Estate are invited. Premiums of £50, £30, and £20. Application (with 19s. 6d. deposit, returnable) was to be sent by January 8th to Lord Aberconway and the Trustees of the Prestatyn Estate, 33, Henrietta Street, Strand, W.C. Designs by March 15th. Judge, Mr. H. V. Lanchester, F.R.I.B.A.

MARCH 16TH. PUBLIC OFFICES, HARROW.—Harrow-on-the-Hill Urban District Council invite designs for enlargement and alterations of their public offices, at a cost not to exceed £4,500. Premiums, thirty, twenty, and fifteen guineas. Plan and instructions (£1, returnable) from

Mr. J. Percy Bennetts, Engineer and Surveyor to the Council, Council Offices, Harrow-on-the-Hill. R.I.B.A. will be asked to appoint an assessor.

MARCH 25TH. SCHOOL, COLCHESTER.—The Borough of Colchester Education Committee invite architects practising within the borough to send in Competitive Plans for a School for about 750 children to be erected on a site in Hamilton Road Colchester. Plans must be delivered by 12 o'clock noon on March 25th. Apply to Ernest H. Bultitude, Clerk, Education Offices, 8, East Stockwell Street, Colchester.

MARCH 31ST. NEW PARLIAMENT BUILDINGS, WINNIPEG.—Regulations governing the competition for the new Parliament buildings for the City of Winnipeg may be had from the High Commissioner for Canada, 17, Victoria Street, Westminster. [The date formerly announced for the close of this competition has been extended to March 31st. Mr. Leonard Stokes, P.R.I.B.A., has been appointed assessor.]

APRIL 4TH. COUNCIL OFFICES, PORTLAND.—Portland U.D.C. offer premium of £50 and £10 respectively for first and second designs. Particulars (deposit 10s. 6d., returnable) from R. A. Colenutt, Clerk to the Council, Offices, New Road, Portland.

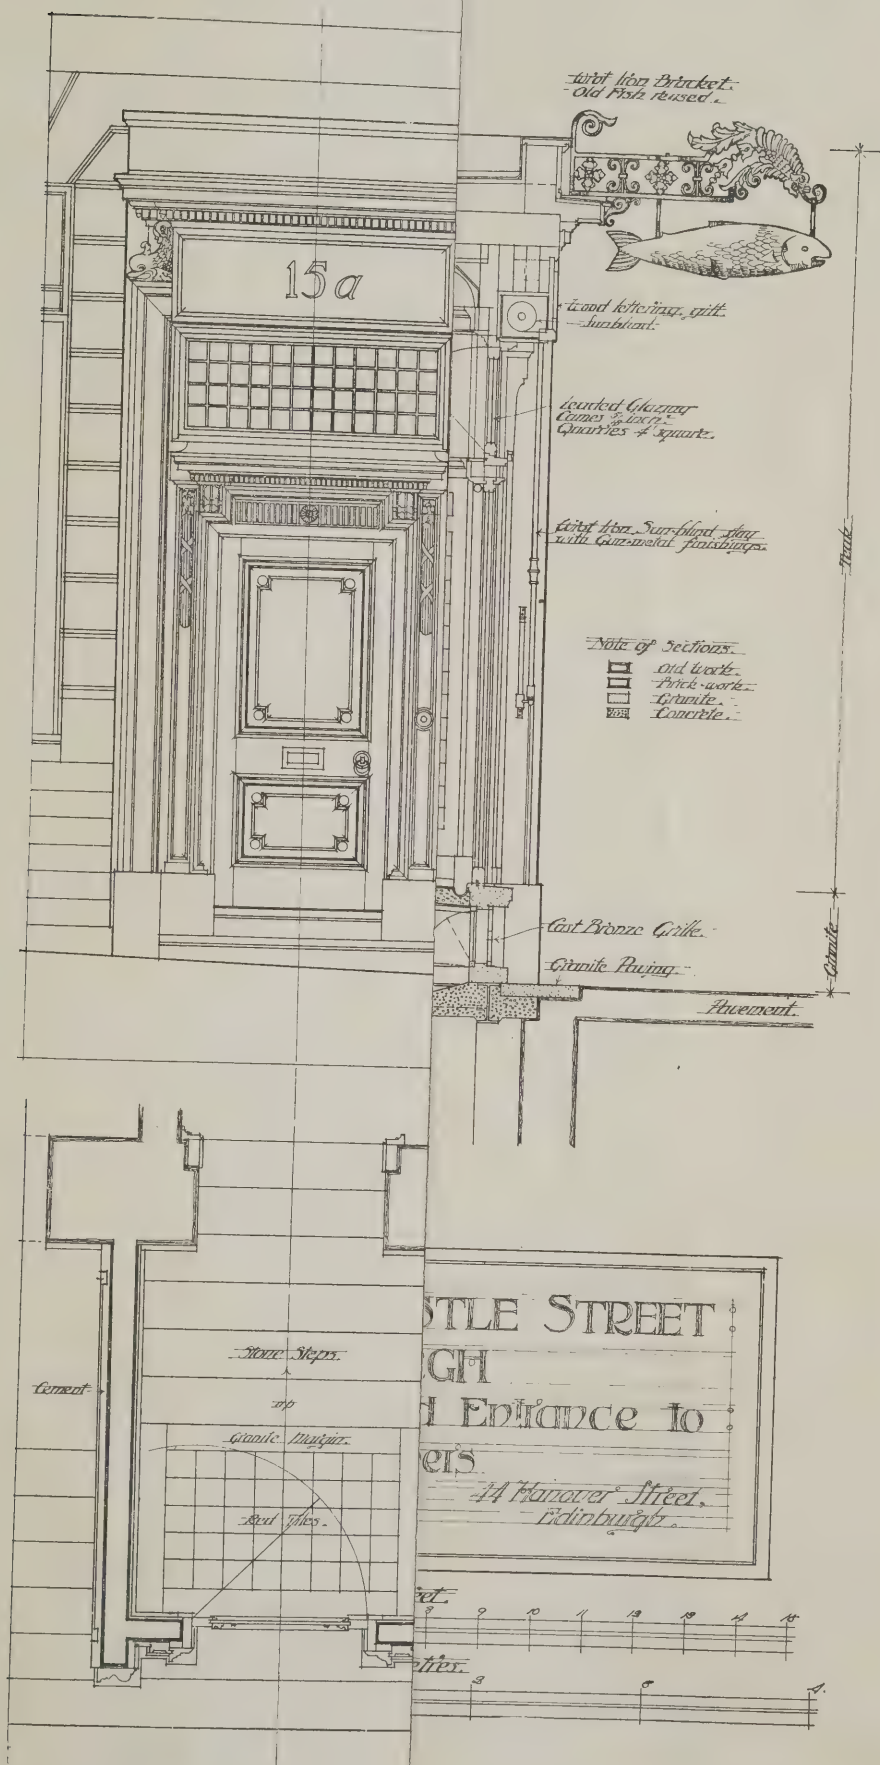

APRIL 20TH. BIRMINGHAM BLUE COAT SCHOOL.—Competition strictly limited to Birmingham architects. In a preliminary competition, three designs will be selected, and the authors will be paid £50 each to develop and redraw the plans to a larger scale, showing further details. In the event of the Governor failing to proceed with the second competition, the authors of the three designs will be paid £25 each. Assessors, Mr. G. H. Hunt, F.R.I.B.A., of London, and Mr. Charles E. Bateman, F.R.I.B.A. hon. consulting archt. to the Governor. Drawings to be delivered by midday of April 20th to Mr. William I. Bolton, Secretary, The Blue Coat School, Birmingham.

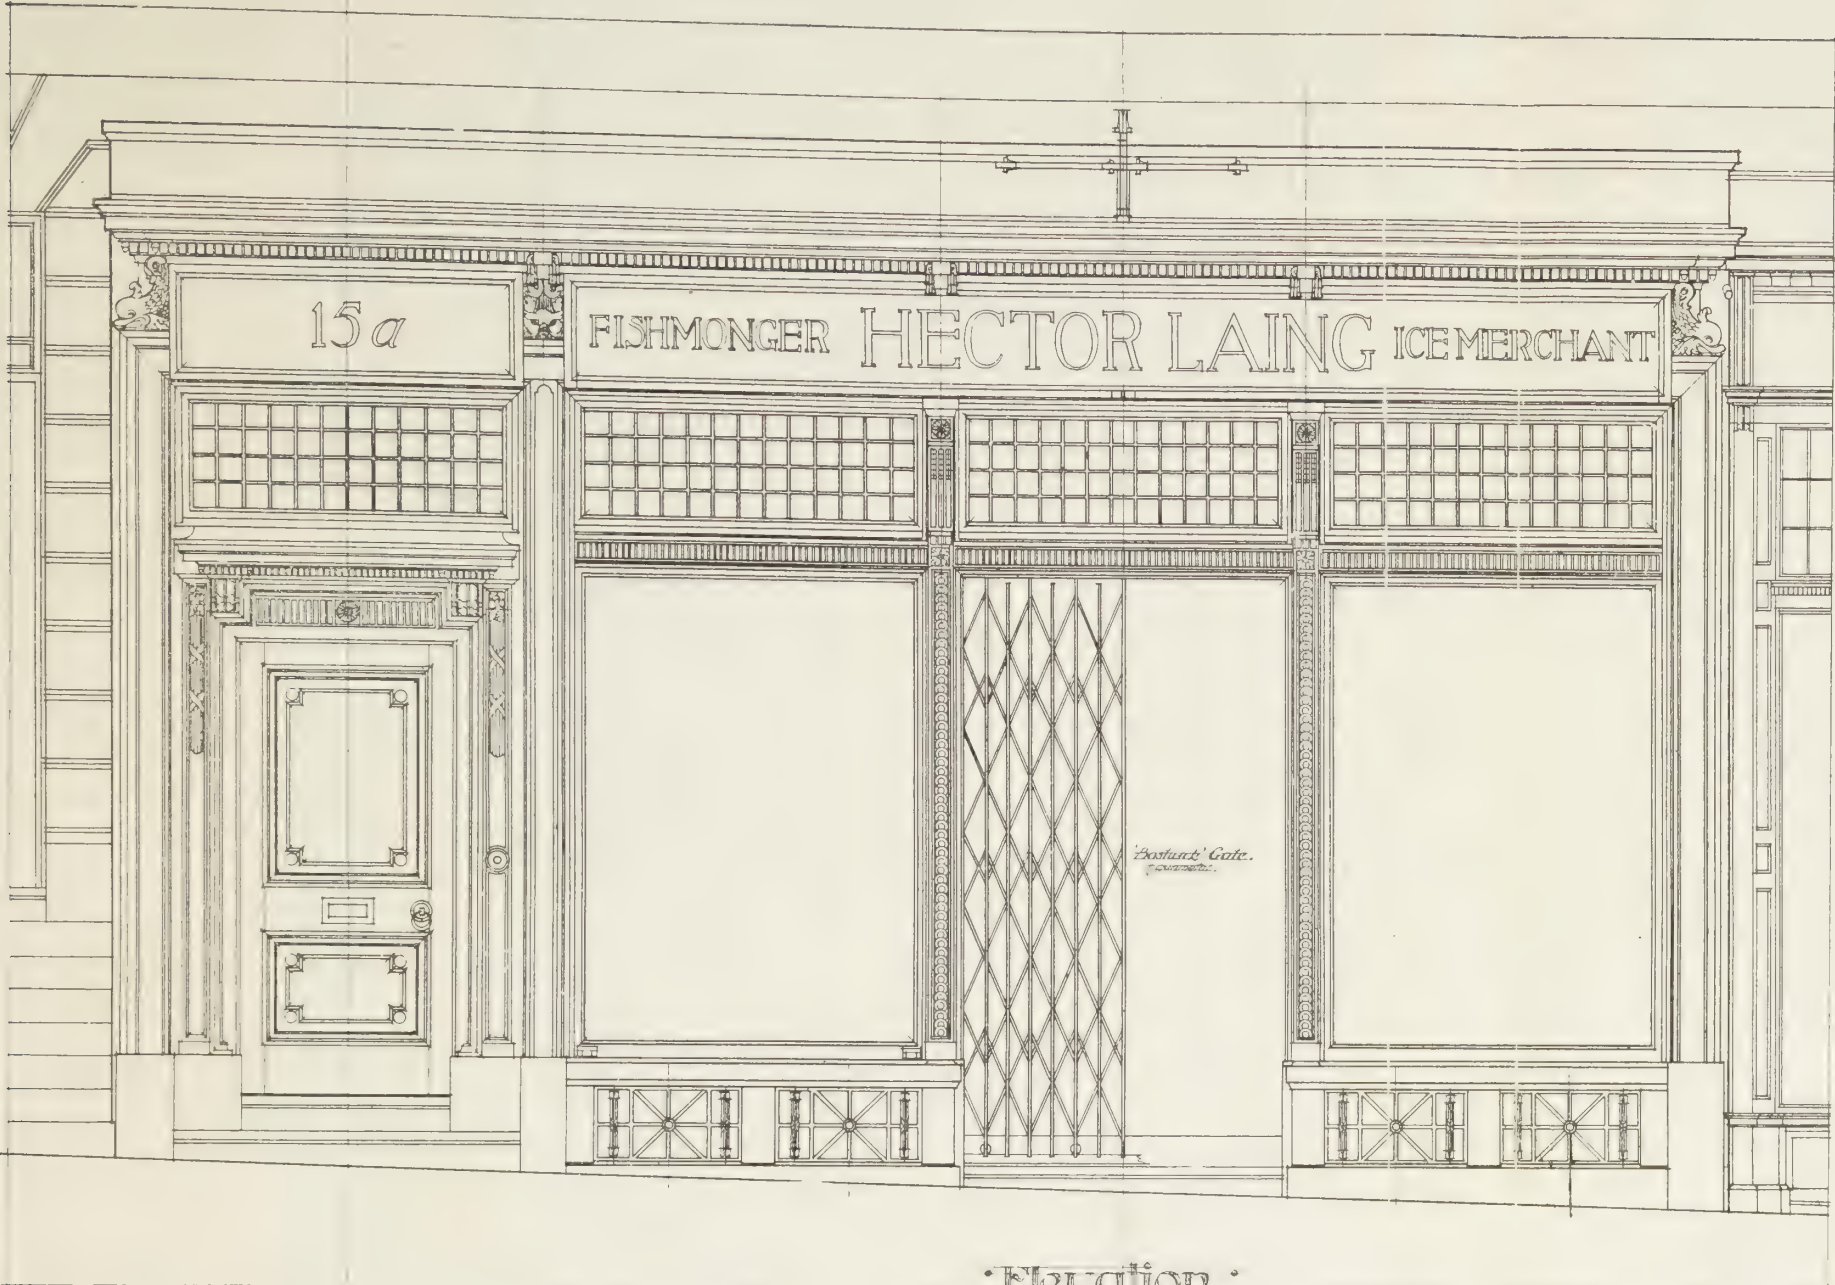

MAY 1ST. PUBLIC BATHS, WOMBWELL, YORKS.—Wombwell U.D.C. invite designs for swimming-baths to be erected at Hough Lane. Premiums, £40, £30, and £20. Stamped and addressed envelope to W. Quest, surveyor to the Council, Town Hall, Wombwell.

JUNE 28TH. TOWN PLANNING, HALE.—Premiums of £50 and £25 are offered for a town-planning scheme.—Address Council Offices, Hale, Cheshire.

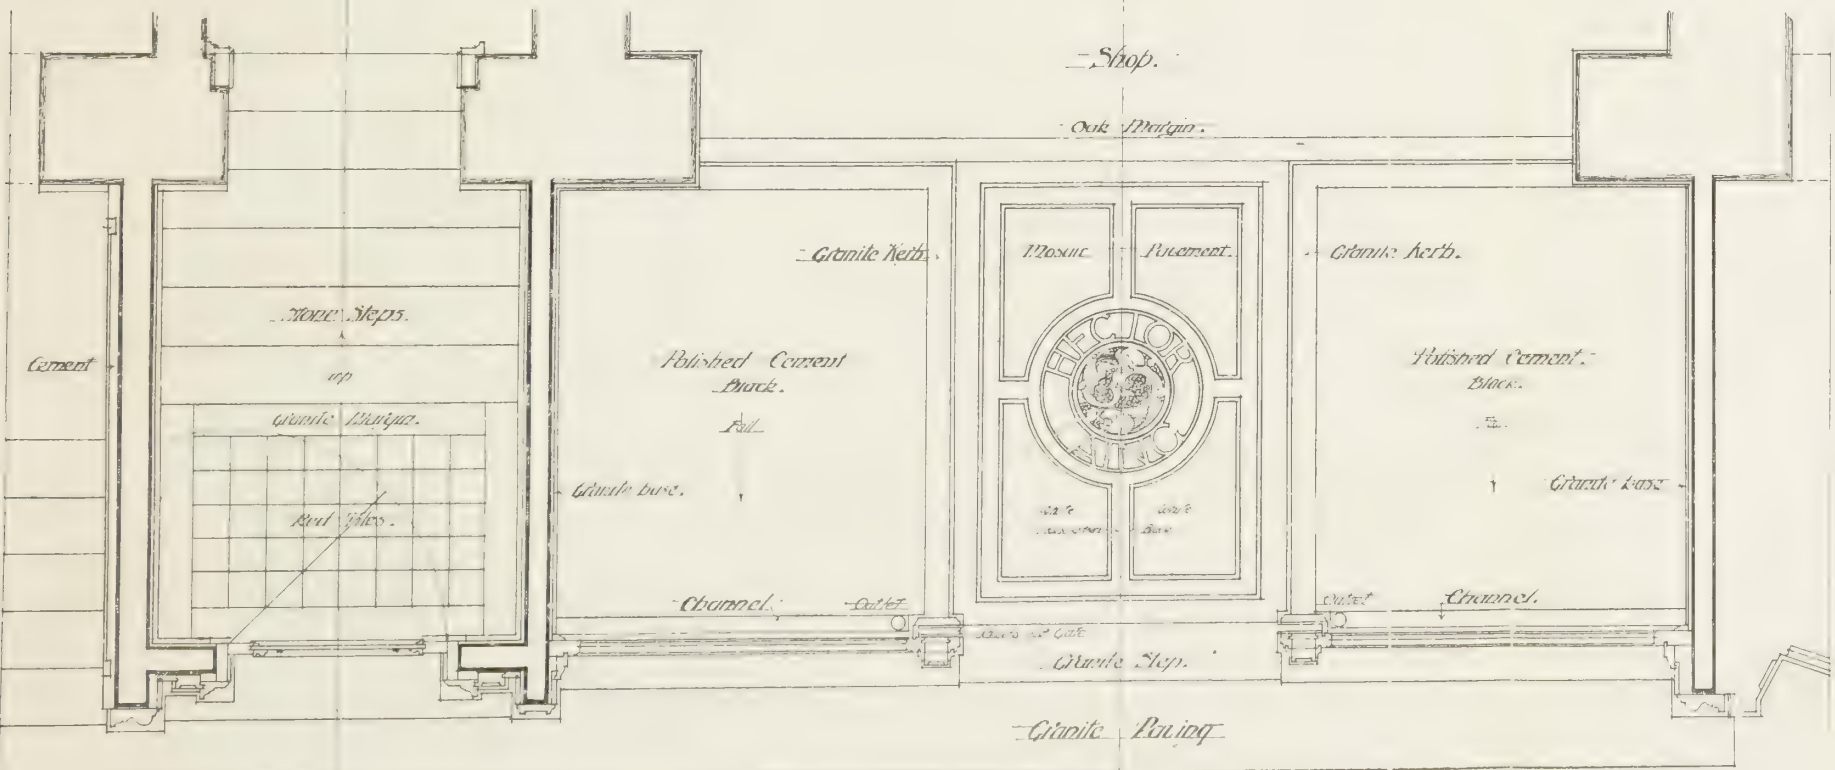

AUGUST 30TH. THE HENRY SAXON SNELL ESSAY.—The Henry Saxon Snell prize of fifty guineas and silver medal of the Royal Sanitary Institute is offered for an essay on "Suggestions for Improvement in the Ventilating, Lighting, Heating, and Water Supply Appliances and Fittings for an Operating Room and its accessory rooms for a General Hospital of 40 Beds (no Students)." Essays (in which two competitors of different profession or crafts may join) to be delivered before 4 p.m., August 30th, to the Secretary Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., from whom full particulars may be obtained.

NO DATE. ELEMENTARY SCHOOL, WARRINGTON.—The County Borough of Warrington Education Committee invite designs for the erection of a public elementary school. Deposit, £1 (returnable). Apply J. Moore Murra, Secretary and Director, Education Office, Sankey Street, Warrington.

A CONVERSATION ON BRIDGES.*

BY PAUL WATERHOUSE, M.A., F.R.I.B.A.

MR. WATERHOUSE'S lecture before the Architectural Association on Monday, February 12th, took the form of a conversation between himself and two imaginary friends—Harper and John Pargeter. After some preliminary discussion, Harper said: "I thought you were going to let us talk about some definitely architectural object." "And pray," said Pargeter, "are not bridges architectural?" "Hardly," said the other. "It is true that bridges occasionally seem to demand and sometimes get a sort of architectural finishing off, such as the Doric columns applied to Waterloo Bridge; but I regard a bridge *per se* as a mere constructional problem, the meeting of a special mechanical need by an economic use of the particular material most suited to the special exigencies of the place and the age. It isn't cut in for a moment," he went on, "Pargeter was preparing to speak, 'I have something to add, for I have thought a good deal about this matter. My consideration of beauty in bridges leads me to the conclusion that beauty in their construction is merely fitness, and that our notions of applying architectural trappings to what is really a mechanical—in other words, an engineering—device or expedient are generally a woeful waste of purely misapplied ingenuity.'"

Harper ceased, and Pargeter looked at him with astonishment. "You are an architect, Harper," he said, "and it amazes me to hear you say such a thing. I am at one with you about architectural trappings: there is no such thing as applied architecture; but your most excellent definition of a bridge is, to my mind, also the most complete definition of architecture that I have ever heard, 'the meeting of a special mechanical need by an economic use of the particular material best suited to the special exigencies of the place and age.'"

No closer expression of the nature of architecture could possibly be devised, yet you boldly say that a process so described is by the nature of the case not architecture, but—as I understand engineering."

Not quite that," said Harper, "but at it this way. You must admit there is such a craft as engineering, and that it is a necessary craft. We know that an architect by himself could not be entrusted unaided with such a problem as a bridge to span the Thames, by admitting an architect's services as desirable for the finishing-off of the structure which the engineer has devised, we simply insult both forms of art, and probably get a result in which the architecture, struggling with the engineering, produces a complicated falsehood which by its very falsity fails to be worthy the name of art." To which Pargeter replied, "My dear Harper, your exaltation of your position only makes it untenable. Engineers are useful people; as you justly observe, their calling is a honourable one and their work is indispensable, but so far for that matter is the work of a host of other persons who do not legitimately find employment in connection with a bridge, but who would, nevertheless, be quite unsuited to art as

the supreme designers of it. All that you can say about the attachment of so-called 'architectural' trimmings or trappings to an engineer-designed bridge is perfectly fair, but the indecency of them is due to the fact that the so-called architect who applies them is, by his very act, proving himself no architect. Whether engineers approve of the fact or not, a fact it still is that an architect if he be anything at all is by virtue of his name an *over-Workman*. A bridge in an important city is obviously and necessarily an important and conspicuous mass of building—as such it is, if I understand architecture at all, a thing to be committed to and produced by an architect. If the problem involved is such that it demands structural knowledge of which no living architect is capable, that is no sufficient reason why the promoters of the bridge should bar all architects from appointment. Appoint the architect, say I, the best you can find, and let him as an over-craftsman have under him, among his many underlings, the best engineer he can get. But somehow or other your questions and my answers have led us to the wrong end of our subject. I wanted to show you how strangely we have been led by familiarity to ignore the miracle of bridges, but we have become plunged into the final and crowning topic, the artistic construction of large bridges in important cities. May I lead the discussion back to the other end of the scale—the primeval bridge?"

"By all means," I said, and Harper said "By all means" also, but he said it as it seemed to me with half a sigh of resignation. Our talk had so far been in Pargeter's little summer-house, built against an angle of his square-walled garden, but as he suggested that we should continue the conversation in the house we both rose to follow him, and Harper, motioning to me to hang back, began murmuring, "I can give you the heads of our friend's discourse beforehand. Aboriginal savage at bank of stream; food supplies or prospective wife viewed on opposite bank; tedium of travelling up stream to find shallows for fording; accidental discovery of fallen tree across stream; application of reasoning faculty; tree felled on purpose in favourable wind; tree too short; selection of rock in mid-stream; device of two trees resting on said rock; dawn of engineering; rudiment of pier; further advance by use of two trunks and transverse sleepers, development of lintel or beam bridge. Conqueror introduces arch; astonishment of savage; progress of arch construction; introduction of iron; arch superseded; return to lintel forms; invention of cantilever. Digression on trusses, and beams again introduced to useful savage in order to trace development of suspension bridge from lowly origin as a mere thong of bullock's hide slung across the stream from tree to tree, up to the elegant structure at Clifton."

Low as Harper spoke, the conclusion of his summary was greeted by a clapping of hands from Pargeter, who, apparently, had heard every word of it. "A very good analysis," he laughed, "of the history of bridges; but I fear I must disappoint you, for I have no inclination to follow the subject on those lines.

Historical development is all very well and very interesting, but I think we shall give ourselves more pleasure by studying the matter in another way.

"Suppose we begin by asking one another, 'What is a bridge?'" "That is easily settled," said Harper. "A bridge is an arched or other structure across a stream or river." "And what do you say," said Pargeter, turning to me. "Harper's definition," I answered, "is a little too narrow; for, to begin with, the bridge needn't be across a stream at all, but might be, and often is, across a road or across a dry chasm." "Yes," said our friend, "and there are also cases where, instead of carrying a road over water, the bridge carries water over a road." I expect that the best definition of a bridge that we can give is, 'a structural device for carrying a road over an obstacle, or an obstacle over a road.' For general purposes that will meet the case, though there would be exceptions even to this, as in the instance, for example, of an aqueduct carrying a canal or a water supply over a river.

"I said" (he continued) "that I did not want to start historically with the savage and the tree trunk, but I must ask you, for the interest of the thing, to imagine yourselves for five minutes to be men whose civilisation has never brought them within reach of the wonder of the arch. You live, let us suppose, by the shore of some mighty river, one of those terrific giants that cannot be bred in an island as small as ours, but need for their nurture long miles of wide continent. Your river comes from hills so remote that you have never seen them, and has rushed through plains so vast that other kings than yours reign over them. Indeed, so great is its force and its severance that the very folk you see lessened by distance on the other bank speak a tongue that you cannot understand.

"One day a man comes among your townsmen and says, 'Give me of your money and I will make it easy for you to walk dryshod in ten minutes from shore to shore.' You laugh at him and suggest that the days of Moses and the Red Sea, of Joshua and Jordan, are not your days. But the man persists, and you ask him how. 'A bridge,' says he. 'A bridge?' you answer, and laugh with greater scorn. You have seen to be sure the arrangement of planks and beams which crosses the streams in your own street, but you know that no such structure could possibly be made to cope with the vast width and the murderous floods of the cold grey monster of which you are so proud and so afraid.

"Then the man speaks again and more madly, as it seems. 'I shall do this thing,' he says, 'not with the lightest and longest materials, but with the shortest and heaviest. Some of you have become used to the wonder of stones piled on stones to make a house: it is on stones that I will cross, and make you cross your river. Not stepping stones, nor a paved ford, but stones that leap from shore to shore, resting here and there on the solid bottom, but bounding from one resting-place to another, flying in curve after curve, but owing all their flight to that very weight which seems to make the deed impossible.'

"Would you believe him? Not you. The thing is a miracle, you say, and miracles do not happen. Your madman makes his bow and goes. You have your laugh out, and a merry laugh it is, for you have kept your money and got rid of

your madman. And after all, you say, it is of no use to go against nature, and the river was placed where it is for good reasons.

"Next year you see a man on the opposite bank. Those few who sometimes venture out on to your river in perilous boats have seen him nearer, and assure you that he is your old friend the madman. You laugh again, realising that the silly citizens of the further shore are likely to be wheedled out of their money in a fool's venture.

"The weeks, the months go by, and at last you see that at the dry end of the summer the man is in very truth at work building a pile of masonry on the bit of shingle that crops up in the centre of the river-bed during August. This is followed by a clever diversion of the current from another part and the building of another heap of mortared stone. Bit by bit through two long seasons, hindered constantly by rising water, and stopped for whole months by the spring's deep floods from the melted snow, the work goes on, till a goodly row of stout mounds of masonry stem the water with their prow-like starlings. You laugh less; but next summer you laugh louder again, for you see timber, undoubted timber, stretching from one pier to the next. Our madman, you cry, has failed at last. His dream of leaping stones is over. He sees that he cannot span his spaces with boulders, and has gone back to the old tree-trunk device, which is good enough for the little stream up street, but will, as we know, be carried away by the first rush of winter water. But your laugh is not long. The logs were carried away, sure enough, but not by storm and stream. They were neatly taken down and stored when they had borne for a while the weight of the first proud bow of hewn rock that was a summer's work of the man with the mad vision. And so, arch by arch, it came. A man like yourselves—only, as you say, madder (as some say wiser)—took of the stones that sink, took of the very sand that the river makes by the boisterous pounding of rocks, took of that human skill which the hungry waters delight to drown, and made from them the conquering arching all but living thing on which one autumn day you celebrated, with fluttering flags and music, with wine and gay clothes, the triumph of human wit over inhuman water."

"Before we get into too exalted a frame of mind on this subject," said Harper, "may I venture to point out that, interesting as bridges are from a structural point of view, they are (even if I admit your claim that they are architectural) necessarily, and for very clear reasons, lower down in the scale of sublimity than most other architectural projects. Their utility, their strenuous economy of material, their publicity—for they are generally for public or common use—and, in fine, their rather commonplace drudgery of service, all serve to mark them off from the monumental aspects of architecture as belonging to a very useful and very necessary, but not in the highest sense artistic, class. In fact, if you are going to make much of bridges you must logically go on to make architectural capital out of roads, for, say what you will, bridges are for the most part very little more than incidents in road-making. And it would puzzle even you, Pargeter, to preach an art sermon on highways."

I realised that Harper, who began these remarks in all seriousness, had ended

by saying a good deal more than he meant, probably for the direct purpose of getting our friend into warmer enthusiasm. He was quite successful; Pargeter was glowing, but with a sudden thought he pulled himself up and said very calmly, as if changing the subject, "Did I ever tell you the story of the Sunday-school teacher from Norwood?"

"I had met the man," said Pargeter, "at Nîmes. We travelled together for a few days, for I found that the little creature was very full of real interest in historical matters; he had quite a poet's heart, and was capable of excitement when other people, better bred, but with blunter appetites, would only show languid appreciation. So I arranged to go with him to the Pont du Gard. He knew that he was to see a Roman aqueduct, and he knew what an aqueduct was, but I wanted him to come upon it by himself. So we had our out-of-door *dejeuner* at the little inn which stands just out of sight of the great arches, and when it was over, I told him to wander slowly up the valley, and I would follow him.

"Judging the time, I set out, and got to the point of view without discovering him. He was nowhere in sight, but he was in sound. At least, that voice was surely his, but the words seemed unnatural to his meek and well-ordered mouth, for they were the words of a swearer. 'Anything wrong?' I shouted, supposing that a sprained ankle was the cause. 'Wrong?' he answered. 'No, I don't think anything is wrong. Why?' 'Oh,' I said, 'you were using pretty strong language when I came up!' He blushed. 'You didn't think I was profane, I hope,' he said. 'I really wasn't, but there is something about this—this monster that made me call out in the strongest and longest words I knew. Of course, I know it is only a water-main, just like the pipes under the road at home in South London, but somehow, coming on it all of a sudden in this country valley among all the flowers and butterflies, and seeing it that size, filling the whole place up like that—sort of drowning the landscape—well, I don't know but what the water-main idea doesn't fairly make it worse. It upset me. Now, if it had been a triumphal arch, or a bit of a basilica or something, I could have taken it quietly, but to find a lonely, out-of-the-way valley simply absorbed by a mass of pure common sense, so huge and so ancient, makes me feel that I must either swear at it as a work of the Devil or say my prayers. Either way I get into the big words.'

"I explained to him that his attitude was a perfectly proper one, that it had an exact counterpart in the feelings of the Queen of Sheba, in whose case the crowning wonder, that made her feel that she had no spirit left in her, was not the temple or the palace, but 'the way by which Solomon went up' from one to the other—doubtless a bridge—and I further assured him that the Romans themselves were so satisfied of the Divine potency of bridges as to call their own high priest by the simple title of chief bridgemaker, a title which to the present day a great part of Christendom gives to its head bishop—Pontifex or Pontiff. On the whole I recommended him, of the two alternatives, to say his prayers, for, whatever moral failings the Romans may have had, they certainly rose above common humanity in the building of bridges, and there is no reason for suggesting that this rising was in the direction of, or even under the direction of, Satan.

"Devil's Bridge, however, is a title which often alights upon a bridge, especially upon such a one as stands inhumanly supreme in a desolate place. Here is one—another of the sketches—from the neighbourhood of Barcelona. Puente del Diablo they call it, and it happens, though you would not think it, to be of Roman origin. The little structure at the far end is the relic of a Roman triumphal arch, and the tall pointed central arch, from which the Roman character has disappeared, is later substitute for two older arches, the central pier having no doubt failed.

"The relation of the whole design to its Roman original seems to me analogous to the Spanish language—a half-Moorish graft upon Latin. The change of the Latin *Pons* to *Puente* is the same frivolous transformation that the bridge has undergone.

"If the Devil built the Roman bridges who built Napoleon's? What do you think of this one from the French side of the Pyrenees? Whether it is a true product of Napoleon I do not know, but it is an absolute poem on all that that word 'Napoleon' means. That leap is rash and yet so assured, that exact fitting of available means to an end, and, to crown it all, that trim bit of Roman assumption in the parapet. Add to that the position in Nature, the rugged, lonely, and defiant spot upon which the hand of a resistless man has been laid with infinite delicacy, yet infinite pertinacity, and you have here a sonnet or an essay clearer than any in mere words."

"Surely," said Harper, interrupting "you are beginning to fly rather high in your rhapsodies! The simple fact probably is that the bridge in question presents, in the absence of steel or chain construction, the most obvious and practical device for the purpose. It is really difficult to understand what simple expedient Napoleon (or the Devil, if that matter) could have adopted."

I ventured to cut in with the suggestion that, after all, the span—as I happened to know—was 150 ft., and that, whether I looked upon the structure as poetry or prose, devilish or divine, it certainly needed a bold mind to entertain the idea of flinging a bridge across such a chasm at all. Humbler men in a less enterprising civilisation would have been content to master the difficulty by taking a circuitous route.

Said Pargeter: "If you are a man of sensibility at all—in the good Jane Austen sense of that word—you can't look upon bridges in any but a sentimental light. Bridges are full of sentiment steeped in it, and unless you are accustomed to go through the whole of seeing nothing but facts and figures, you are compelled to receive something of a message which almost every bridge bears."

"Charing Cross Bridge, for example," said Harper, "and that which extends from Cannon Street Station like a snake from its loathsome lair!"

"There," said Pargeter, "you realise it have me. Let us wipe out the thought of the poor old Thames by the refreshment of a glance at Florence—Florence from the Miniato, one of the fairest prospects of the whole world, and a prospect of which the bridges are the fairest part. I hardly fair" (he went on) "to compare London with Florence, for if there is anything more than another that bridge express it is nationality; so let us set for a minute this sketch of Durham. See the rugged British force of the wall."

composition. The bridge belongs to the Cathedral. Its slope emphasises the height of the crag on which the Cathedral stands, and its irregularity—lack of uniformity between one arch and another—adds immensely to the rough vigour of the scene. A suspension bridge can be, and often is, a lovely thing, but imagine, if you can, a suspension bridge taking the place of Durham's rude causeway, and you will realise that it would spoil the picture absolutely.

"There is great charm about a bridge with something on it—of course, as an alternative to the bridge which is a bridge alone. That is one reason for our bitter regret at the loss of old London Bridge. That and Florence's Ponte Vecchio, and in a different degree Venice's—or shall I say Shakespeare's?—Rialto Bridge, are instances of the instinct to make good financial use of the space which the bridge has won from the water—a picturesque act of commercialism which might well be repeated in modern times. Why we habitually shrink from the chance of making a bridge pay rent for its existence by a row of shops is more than I for one can understand.

"Of bridges with things on them there are several kinds. There is the covered bridge, of which there are two at Lucerne; there is the bridge with a chapel, of which England has an ancient example at Bradford-on-Avon; there is the noble bridge at Pavia with both roof and chapel. Then there is the festive Roman idea of a bridge with one or two triumphal arches. We saw the rudiment of this in the Puerta del Diablo; a better example is the bridge at St. Chamas, of which I have found an old engraving. Even you, Harper, must allow that such a bridge is sentimental, for a triumphal arch has no meaning whatever but a sentimental meaning. It is a costly expression of pride."

"I am not quite so sure of that," said Harper, "for you will probably find that a good many so-called triumphal arches are in reality merely glorified versions of toll-bars or customs-barriers, and those placed upon a bridge may very probably have served both purposes."

I asked Pargeter if there were any sketch of the bridge at Avignon. "Alas! no," he said. "I wish there were. Such a bridge as it must have been! The lean fragment that remains is like a greyhound—a bit of tense, almost muscular, masonry. Its very destruction seems to show how fine in its case was the margin between weight and energy."

"And what have we here—the last in the portfolio? The bridge of Prague. What a change! Here is nationality with vengeance. No English town, no French could have expressed itself in such a guise. Look at its gallery of statues; look at its towers, at their challenging inequality, their fantastic shape! The crucifix that crowns the bridge's centre was paid for, they say, from the fine laid upon a Jew who had reviled the Cross. There was a riot of faith, and faith is a great thing among bridges."

"Depend upon it," he continued, "every bridge has had a bridge-maker, pontifex, and every pontifex is a priest, and every priest has his message."

"Nationality, character, mood, temperament, welcome, defiance, joy, gloom—all these are songs that a bridge can sing. But through them all and with them all it sings by its mere being, by its mere act, the song of the passing, the song of the river crossed, the song of the

coming over, which is an overcoming. And for those that overcome there is a crown."

We two came out from Pargeter's room and said good-bye. I walked home with Harper. We didn't talk for a space. Then I said, "You rather curbed our friend once or twice, but I dare say you did well or meant well in bringing him down to earth. Anyhow, I know he never thinks the worse of you for it."

I said this because I thought he might be feeling remorseful.

His reply rather astonished me. "I don't care," he said, "what Pargeter thinks, but I am sure that in all he said to-day he was perfectly right."

DISCUSSION.

Mr. W. T. Dunn, proposing a vote of thanks, said that as engineers they had expected to hear something in regard to the design of bridges, and something with respect to material. Reference to Charing Cross bridge had naturally raised a smile; but, nevertheless, he would rather like to have Mr. Waterhouse's idea of a bridge that had to carry a railway. The lecture, however, was wholly delightful, and it showed Mr. Waterhouse as an artist and a word-painter.

Mr. H. H. Statham, seconding the vote of thanks, said that the lecture was essentially on the poetry and picturesqueness of bridges. No mention had been made of the tubular bridge over the Menai Straits. This was perfectly simple and effective, and had nothing to offend the taste in any way. Engineers, he knew, preferred bridges to be purely engineering structures without any architectural treatment. He had a great admiration for the Forth Bridge, but if any attempt were made to ornament it, it would become a mere gimcrack. Referring to mediæval bridges, Mr. Statham cited the one at Chester which, being built where the river was cut up by banks, had a natural picturesque appearance. Another was the bridge at Huntingdon, built in the first half of the 14th century. Reference had been made to the way in which bridges were built under Napoleon. The Emperor had always been anxious to have things done in the most solid manner, and of this fact the now double bridge at Passy, over the Seine, was a good illustration. It became necessary, a good many years ago, to carry a railway over this point, and so solid was Napoleon's bridge that a great stone railway viaduct had actually been built along the centre of its roadway. That this had been possible was highly creditable to the ruler and to the builder of the bridge.

Mr. Percy J. Waldram said that no engineer would be able to look at the design of a bridge thenceforward but in a new way. The eternal question between the architect and the engineer was whether the engineer knew enough of architecture and the architect enough of engineering. It was instructive to note that the greatest triumphs of architecture were those closely connected with a knowledge of stresses, strains, and thrusts. If bygone architects did not ignore engineering, neither, surely, should those of the present day. With regard to materials, the use of reinforced concrete in bridgework was open to objection. Reinforced concrete was really weaker than wood, and the necessity for reinforcing large arches pointed to a defect in the design of the arch. If an arch were truly designed it should follow the line of thrust. Masonry under the Romans, he continued, was

splendid until it began to decline and brought about the introduction of the pointed arch. Architecture and engineering, he thought, were not alien to, but complementary of, each other.

Mr. J. J. Burnet said that no artistic thought of a bridge should take away the idea that it was to fulfil a practical purpose; but they had got to read as much poetry into the design as they could. The bridges at Prague and Toledo, he thought, were good examples of the bridge form brought into harmony with the surroundings. The fault of the architect and the engineer was that neither knew enough of the other. The integrity and purpose of a bridge should be simple and open, so as to be understood by everybody.

Mr. Percy Young referred to some of the Thames bridges, particularly Battersea and Putney, which had not anticipated traffic requirements.

Mr. Arthur T. Bolton said that when in Spain he had met an artist who had come across the late Mr. Alfred Waterhouse, when he was making his Continental sketches, for which he expressed great admiration. Waterloo Bridge, said Mr. Bolton, was remarkable for its fine finish at either end and for the introduction of the architectural element. The Doric columns always seemed to be part of the bridge itself. Rennie was directly related to Cockerell, to whom, in his autobiography, he made regretful references that his designs for bridge approaches had not been carried out. Having referred to the Rialto Bridge, Mr. Bolton said it had always been one of Palladio's dreams to erect a bridge with a colonnade stretching along it. He could see no real objection to the introduction of covered bridges in London.

Mr. Philpot said that reinforced concrete construction would not be satisfactory for a bridge to sustain moving loads.

Mr. H. W. FitzSimons mentioned a number of difficulties encountered in modern bridge construction. What, he said, would Parliamentary Committees say nowadays if it were proposed to build bridges with small spans? The requirements usually were that spans should be as large as possible, that there should be the highest possible head-room and the flattest possible gradient; and it was very difficult to bring these points into proper relation. Referring to the Forth Bridge, the speaker said, whether it had twice its metal or not, it was designed by a capable and eminent engineer who knew his work; and in most parts of the structure the steel was stressed up to a very high pitch.

Mr. S. Bylander said in olden times stone was employed because it was the best-known and most suitable material. Steel was now used for a similar reason. He thought it was not impossible to make a steel bridge beautiful. With respect to reinforced concrete, his view was that it was entirely a question of economy. A bridge could be made quite strong enough of concrete alone, but it would require a great thickness of concrete. By the introduction of steel the design was made more economical.

Mr. Gerald Horsley, in putting the vote of thanks, said he hoped that from that meeting would grow up a better understanding between architects and engineers.

Mr. Paul Waterhouse, in reply, suggested that the ideal solution of the problem would be for one individual to combine the qualities of both the archi-

tect and the engineer in himself. The craft of both was so big, however, that it seemed impossible ever to get to the end of it.

With respect to the Forth Bridge, he could only say he thought it an ugly thing, yet one of the most worshipped things in the world.

[Mr. Waterhouse's paper was illustrated by a number of lantern slides made from drawings by the late Mr. Alfred Waterhouse, R.A., the originals, which had not previously been shown in public, being exhibited upon the walls.]

BOOK NOTICES.

Spon's Architects' and Builders' Pocket Price Book and Memoranda.

Many occasions arise when the architect or the builder would be very glad to have on his person, for instant consultation, the means of ascertaining or checking a price, or of referring to authentic memoranda of some of the thousand-and-one items which cannot and need not be carried in the most retentive memory. The books under notice fulfil these requirements very conveniently. Slight in bulk, and having durable but flexible covers with rounded corners, they can be comfortably carried in a pocket of normal dimensions, and in each case the contents are arranged so admirably as to leave but little to be desired in the matter of facility of reference. Systematic tabulation, marginal subject-indication in black type, and a full index, enable the user to find any item at a moment's notice. In the Price Book a diary is usefully included. This book is arranged in the usual order

of trades; but the items in the volume containing the memoranda are in alphabetical sequence. In the latter volume several useful diagrams are included; and the memoranda seem to include every detail that is at all likely to occur in ordinary practice.

"Spon's Architects' and Builders' Price Book and Diary, 1912"; and Spon's Architects' and Builders' Pocket Book, Memoranda Section, 1912. Each, price 2s. 6d. net. London: E. and F. N. Spon, Ltd., 57, Haymarket.

Drainage Work and Sanitary Fittings.

It is not difficult to understand why Mr. William H. Maxwell's handbook on "Drainage Work and Sanitary Fittings" has run into a third edition. Its subject is to a certain extent of general interest, and appeals, moreover, to the members of various professions, to whom a more or less intimate knowledge of sanitary work is essential. This book, besides being cheap, has the merit of succinctness, and should therefore be a boon to the busy man, as it places him in possession of essential data without putting him to the trouble of digesting or tabulating them for himself from out the usual welter of superfluous verbiage. The book contains many illustrations, and should have been provided with an index to the many useful items of information which is incorporated.

Drainage Work and Sanitary Fittings. By William H. Maxwell, A.M.Inst.C.E. Third edition, revised and enlarged. London: The St. Bride's Press, Ltd., 14, Bride Lane, Fleet Street, E.C. Pages xii. + 128, 7½ins. by 5ins., 2s. net.

Theory and Practice in Structural Design.

The chief merit of this book is its clearness of elucidation. Principles are stated in the simplest possible language, and are almost invariably illustrated by means of thoroughly practical examples

of their application. The author is evidently a firm believer in the educational value of an appeal to the eye, and the 370 diagrams are distinguished by exceptional legibility, as well as by extreme neatness of draughtsmanship. Loads, stresses, bending moments, shearing forces, section modulus, and, indeed, all essential considerations pertaining to the principles of safe and efficient design, are explained graphically as well as verbally, and afterwards the various structural members commonly in use are discussed severally and in combination. The book should serve as an excellent introduction to a subject in which a clear grasp of elementary principles is essential to sound practice.

Theory and Practice in Designing. By Henry Adams, M.Inst.C.E., etc. London: Constable and Company, Ltd., 10, Orange Street, Leicester Square, W.C. Pages xviii. + 240, 8½ins. by 5½ins., price 6s. net.

DETAILS, OLD & NEW, XXXVIII.

Shop Front, 15, Castle Street, Edinburgh.

The front illustrated is of teak, duly french-polished. The base is of grey granite, with cast-bronze grilles protecting the stall-board lights. The ingoos to the windows are tiled with white and Dutch-blue tiles, this being the scheme existing throughout the shop.

The architect was Mr. W. J. Walker Todd, Edinburgh; and the contractors were as follows:—joiner work, Mr. Nathaniel Grieve; granite and tile work, Messrs. J. Allen and Sons; wood-carving, Mr. Thomas Good; wrought-iron sign, Mr. Thomas Hadden; bronze grilles, Mr. Charles Henshaw; electric lighting and blinds, Messrs. John Bryden and Sons; all of Edinburgh.

SHOP FRONT AND ENTRANCE TO CHAMBERS IN CASTLE STREET, EDINBURGH.
W. J. WALKER TODD, ARCHITECT.

NEW LIGHT ON VENTILATION.*

BY LEONARD HILL, M.B., F.R.S., AND MARTIN FLACK, M.A., M.B., B.Ch.

Conventional theories with respect to what may be termed the natural philosophy of ventilation are, to some extent assailed by the authors of this paper, whose conclusions, whether or not they are accepted, are based on painstaking investigation, and are therefore specially worthy of the close and earnest attention of all to whom the subject is of practical as well as of vital interest.

THE good effects which result from efficient ventilation and open-air treatment are generally supposed to be due to the chemical purity of the air. They are due really to the movement, coolness, and relative humidity of the air, and to the ceaseless variation of these qualities.

A "Great Illusion."

The ventilating engineer has hitherto followed a great illusion in thinking that the main object to be attained is chemical purity of the air. The heating engineer has sought after an equally great illusion in striving to give us a uniform summer temperature. The ventilating and heating engineers primarily should aim at giving us air which is cool, of proper relative humidity, and which moves so as to vary the cutaneous state of the body. Our comfort and discomfort in crowded rooms and shut-up places depends, not on the chemical purity of the air, but, to a minor degree, on the influence of the smell of the air on the olfactory sense, and, to a vast degree, on the influence of the temperature, relative humidity, and the variations of these qualities of the air, which act on the real field of cutaneous sensibility.

"Chemical Purity" Discounted.

It is needless to point out that our sense of well-being depends to a very great degree on the comfortable condition of our skin, and yet the ventilating and heating engineers have paid little attention to this. While asserting that the chemical purity is of no account, we make no proviso that the air is only altered by the presence of human beings, and is either rendered poisonous by the escape of coal gas or other noxious trade product, or deoxygenated by the oxidative processes of the soil, as it is in mines. We are speaking of the discomfort and ill-health caused by the deficient ventilation, or bad methods of heating, dwelling-houses, schools, factories, theatres, chapels, &c.

The chemical purity of the air can be considered from three points of view, the concentration of CO_2 , the concentration of O_2 , the supposed presence of organic poisons exhaled in the breath.

Owing to the fact that a percentage of O_2 is not legally permissible in factories which exceeds a very few parts per thousand, it is commonly supposed that any lack of excess of CO_2 acts as a poison.

Of Fundamental Importance.

The truth of the matter is quite otherwise; for, whatever the percentage of O_2 in the atmosphere may be, that in pulmonary air is kept constant at about 5 per cent. of an atmosphere by the action of the respiratory centre. It is the concentration of CO_2 which rules the respiratory centre, and to such purpose to keep the concentration both in the lungs and in the blood uniformly about the same. This fact, which was first fully established by Dr. John Haldane, is of fundamental importance.

Extracts from a paper read before the Royal Society of Arts, February 7th.

It is impossible that any excess of CO_2 should enter into our bodies when we breathe the air of the worst-ventilated room in which the percentage of CO_2 assuredly does not rise about 0.5 per cent., or at the outside 1 per cent. The only result from breathing such an excess of CO_2 is a slight and unnoticeable increase in the ventilation of the lungs. The increased ventilation is exactly adjusted so as to keep the concentration of CO_2 in the lungs of the normal 5 per cent. of an atmosphere. The very same thing happens when we take gentle exercise, and produce more CO_2 in our bodies; the pulmonary ventilation is then slightly increased, and thus the CO_2 concentration in the blood and lungs is kept at the same uniform level. At each breath we rebreathe into our lungs the air in the nose and large air-tubes (the dead space air), and about one-third of the air which is inhaled into the lungs is "dead space" air. Thus, no man breathes in pure outside air into his lungs, but air contaminated perhaps by one-third, or (on deep breathing) by one-tenth with expired air. When a child goes to sleep with its head partly buried under the bed-clothes, and in a cradle with the air confined by curtains, he rebreathes the expired air to a still greater extent, and so with all animals that snuggle together for warmth's sake. Not only the newborn babe sleeping against its mother's breast, but pigs in a sty, young rabbits, rats and mice clustered together in their nests, young chicks under the brooding hen, all alike breathe a far higher percentage than that allowed in our factories by the officials of the Home Office. To rebreathe one's own breath is a natural and inevitable performance, and to breathe some of the air exhaled by another is the common lot of men who, like animals, have to crowd together and husband their heat in fighting the inclemency of the temperate and Arctic zones. By a series of observations made on rats confined in cages with small ill-ventilated sleeping chambers, we have found that the temperature and humidity of the air—not the carbonic acid and oxygen concentration of the air—determines whether the animals stay inside the sleeping-room or come outside. When the air is cold, they like to stay inside, even when the carbonic acid rises to 4 per cent. or 5 per cent. of an atmosphere. When the sleeping chamber is made too hot and moist they come outside.

 CO_2 of "No Account."

In breweries the men who tend the fermentation vats work for long hours in concentrations of CO_2 of 0.5 to 1.5 per cent. Such men are no less healthy and long-lived than those engaged in other processes of the brewing trade. In the Albion Brewery we analysed on three different days the air of the room where the carbonic acid gas generated in the vats is compressed and bottled as liquid carbonic acid. We found 0.4 per cent. to over 1 per cent. of carbonic acid in the atmosphere of that room. The men engaged therein worked twelve-hour

shifts, having their meals in the room. They had followed this employment for eighteen years, and without detriment to their health. It is only when we come to the higher concentrations of CO_2 , such as 3 per cent. to 4 per cent. of an atmosphere, that the respiration is increased so that it is noticeable to the individual himself, and such percentages, of course, diminish the power to do work; for the excess of CO_2 produced by the work adds its effect to the excess in the air, and the limit of panting is soon reached. Thus the power to work is checked. Divers who work in diving dresses, and men who work in compressed air caissons, constantly work in concentrations of CO_2 higher than 1 per cent. of an atmosphere, and so long as the CO_2 is kept below 2 per cent. to 3 per cent. of an atmosphere, they are capable of carrying out efficient work.

It results, then, from what we have said, that concentrations of CO_2 , such as occur in the most crowded and worst-ventilated rooms, are of no account. Forced to admit this fact, the hygienist has fallen back on the hypothesis that organic chemical poisons are exhaled in the breath, and that the percentage of CO_2 is a valuable guide as to the concentration of these. It is necessary, he says, to keep the CO_2 below 0.1 per thousand, so that the organic poisons may not collect to a harmful extent.

The Question of Oxygen.

Before we turn to the discussion concerning the supposed existence of these organic chemical poisons, we will deal with the question of oxygen. The oxygen in the worst-ventilated schoolroom, chapel, or theatre, is never lessened by more than 1 per cent. of an atmosphere. The ventilation through chink and cranny, chimney, door, and window, and the porous brick wall, suffices to prevent a greater diminution of the oxygen concentration. Now, in all the noted health resorts of the Swiss mountains, such as St. Moritz, the concentration of oxygen is lessened considerably more than this. On the high plateaux of the Andes there are great cities: Potosi, with 100,000 inhabitants, is at 4,165 metres (barometric pressure about 450 mm. Hg.); railways and mines have been built even at altitudes of 14,000 to 15,000 ft. Owing to the nature of the chemical combination of oxygen with hæmoglobin, man can adjust himself to very great variations in oxygen concentration. At Potosi girls dance half the night, and toreadors display their skill in the bull-ring. We have watched our students, shut in an air-tight chamber, until they came to breathe air containing only about 16 per cent. of oxygen and $3\frac{1}{2}$ per cent. of carbonic acid, and seen their puzzled look when they found they were unable to light a match and smoke a cigarette. There was then too low a percentage of oxygen to support combustion, but of this they were quite unaware. All the evidence goes to show that it is only when oxygen is lowered below a pressure of 14 per cent. to 15 per cent. of an atmosphere that signs of oxygen want arise. A diminution of 1 per cent. of an atmosphere has not the slightest effect on our health or comfort.

Exhaled Breath.

We must now discuss the evidence for the existence of organic chemical poison in the exhaled breath. The evil smell of crowded rooms is accepted by most as unequivocal evidence of the existence of such. This smell, however, is only sensed by, and excites disgust in, one who comes to it from the outside air. He who

is inside and helps to make the "fugg" is both wholly unaware of, and unaffected by, it. Fluegge points out, with justice, that while we naturally avoid any smell that excites disgust and puts us off our appetite, yet the offensive quality of the smell does not prove its poisonous nature. For the smell of the trade or food of one man may be horrible and loathsome to another not used to such. The stench of glue-works, fried-fish shops, soap and bone manure works, middens, sewers, become as nothing to those engaged in such, and the lives of the workers are in no wise shortened by the stench they endure. The nose ceases to respond to the uniformity of the impulse, and the stench clearly does not betoken in any of these cases the existence of a chemical organic poison. On descending into a sewer, after the first ten minutes, the nose ceases to smell the stench; the air therein is usually found to be far freer from bacteria than the air in a schoolroom or tenement.

If we turn to foodstuffs, we recognise that the smell of alcohol and of Stilton or Camembert cheese is horrible to a child or dog, while the smell of putrid fish—the meal of the Siberian native—excites no less disgust in an epicure, who welcomes the cheese. Among the hardiest and healthiest of men are the North Sea fishermen, who sleep in the cabins of trawlers reeking with fish and oil, and for the sake of warmth shut themselves up until the lamp may go out from want of oxygen. The stench of such surroundings may effectually put the sensitive, untrained brain-worker off his appetite, but the robust health of the fisherman proves that this effect is nervous in origin, and not due to a chemical organic poison in the air. The supposed existence of organic chemical poison in the expired air is based upon experiments of Brown-Sequard and d'Arsonval. They injected into guinea-pigs and rabbits either the condensation water obtained from the breath, or water which they used several times over to wash out the trachea of dogs. The water was injected subcutaneously and in large amounts, and produced in their hands signs of illness, collapse, and death.

Fallacious Experiments.

These experiments have been repeated by many others, and with negative results by those whose methods of work demand most respect—Dastre and Loye, Van Hofmann, Wellenhof, Lehmann and Jessen, Haldane and Smith, Weir Mitchell and Borgey, etc. A few confirmatory results have been obtained by methods of experiments which are truly absurd in their conception. One to two cubic centimetres of condensation water (obtained by breathing through a cooled flask) have been injected into a mouse weighing 13 grams or so. This is equivalent to injecting five litres of water into a man weighing 65 kilos. Who would not be made ill by the injection of about nine pints of cold water beneath his skin? It has been shown that injections of pure water alone in doses of over one cubic centimetre may make a mouse ill. Such experiments are ridiculous, and deserve not a moment's attention.

After referring to various experiments which had been assumed to show that the breath of man was injurious to certain quadrupeds, the authors said that they doubted the validity of such conclusions.

The question before us is—Do men breathe out a substance poisonous to man? If there were anything in the claims

of the American authors, we should expect to find rats which dwell in the same confined cage and breathe each other's breath sensitive to the injection of a trace of each other's protein. We are informed, by those who study the phenomena of anaphylaxis, that no such sensitivity can be shown.

After studying the literature on this subject we are convinced that there is no positive evidence which demonstrates the poisonous nature of the condensation water obtained from the breath. We go further, and say there is at present no trustworthy evidence of the existence of any such poison in the exhaled air.

The Brown-Sequard and other experiments having been discussed, the comment was made that "It has been proved conclusively that no harm results so long as a sufficient air current is maintained to keep the carbonic acid below a poisonous amount. The animal in the last cage dies when the CO_2 reaches 10 to 12 per cent. If the CO_2 is kept down the animal in the last cage puts on weight and thrives as well as the animal in the first cage."

Temperature and Humidity.

The authors went on to say: Benedict has shown that a man can live many days in a closed chamber in comfort without damage to his health, having not the slightest cognisance of any defect in ventilation, when the ventilation is so reduced that the carbonic acid accumulates in the chamber up to 1 per cent.—that is to say, so long as the air in the chamber is kept cool and dry. We have enclosed eight students in a small chamber holding about three cubic metres of air and kept them therein until the CO_2 reached 3 per cent. to 4 per cent., and the oxygen had fallen to 17 or 16 per cent. The wet-bulb temperature rose meanwhile to about 85°F ., the dry-bulb a degree or two higher. The discomfort was very great, but this was relieved to an astonishing extent by putting on electric fans placed in the roof, whirling the air in the chamber, and so cooling the bodies of the students.

In a crowded room the air confined between the bodies and clothes of the people is almost warmed up to body temperature and saturated with moisture, so that cooling of the body by radiation, convection by evaporation, becomes almost impossible. This leads to sweating, wetness and flushing of the skin, and a rise of skin temperature. The blood is sent to the skin and stagnates there instead of passing in ample volume through the brain and viscera. Hence arise the feelings of discomfort and fatigue. The fans in our chamber whirled away the blanket of stationary wet air round their bodies, and brought to the students the somewhat cooler and drier air in the rest of the chamber, and so relieved the heat stagnation from which they suffered. The relief became far greater when we allowed cold water to circulate through a radiator placed in the chamber, and so cooled the air of the chamber about 10°F .

Ventilation cannot get rid of the source of a smell, while it may easily distribute the evil smell through a house. As Pettenkofer says, if there is a dunghill in a room, it must be removed. It is no good trying to blow away the smell. Houses and people and their clothes and bodies must be made clean, and latrines and kitchens placed on the top of houses, or outside them, and on the windward side. Catarrhal infections are spread by the expulsion of droplets of saliva when speaking, coughing, or sneezing. During

quiet respiration the exhaled breath is practically sterile, for the wet mucous surfaces of the respiratory tract catch all the inhaled bacteria, and no "droplets" are exhaled. Can we lessen the "droplet" infection by ventilation? Fluegge concludes, from the results of his admirably contrived experiments, that we cannot. He says a current sufficient to drive out such droplets cannot be borne by the inhabitants of the room. A moderate ventilation current tends to keep the droplets suspended in the air. In a still room they soon fall to the ground and, clinging to floor and furniture, may be wiped up next morning and removed by the housemaid. We cannot hope to prevent infection in crowded railway carriages, theatres, chapels, schools, etc. The epidemics of common colds that sweep through the community show this only too well. . . . Immunity depends on the quality and flow of the blood, the supply of immunising substances in the tissue lymph, the activity of the ciliated epithelium and phagocytes which form a second line of defence against bacteria. The state of all these defensive mechanisms of the respiratory membranes are modified by the temperature and relative humidity of the air. Exposure to over-heated dry air dries up not only the skin but the membranes of the nose and throat, and so lessens immunity.

Exposure to over-heated moist air brings the blood into the skin, lessens the circulation through the viscera, and deprives us of the stimulating effect of cold on the cutaneous nerves, decreases the evaporation from the respiratory tract, diminishes the muscular activity, and so the amount of oxygen breathed in and food eaten, and thus altogether lowers the plane of our existence. Hence arise diminished health and strength, and increased susceptibility to catarrh. Those who habitually expose themselves to cold rarely take cold.

Virtues of the Open Fire.

We have now dealt with the general principles which ought to control the practice of the heating and ventilating engineer. The old English methods of open fire and open window have very much to recommend them. By the open fire air is kept moving and cool air is brought in; the heating is by radiation and uniformity of the conditions of temperature in the room is prevented. On the other hand, the impulsion of hot air into a room is the most objectionable of all the systems employed. A cool air and radiant heat are the ideal; the hot-air system gives us neither. In cold weather the heated air becomes excessively dry. The vigour and health of children in America have been seriously undermined by the impulsion of hot "desert air" into the schools.

The lecturers then demonstrated the use of the Ozonair Company's apparatus for generating and diffusing ozone.

Ozone as a Deodoriser.

Ozone, they remarked, is a most powerful deodoriser. It takes away a disagreeable smells. Whether it destroys them or prevents the nose smelling them is of little importance. The physical effect is the same—the disguise due to the evil smell disappears. Ozone should be present in the air for continuous breathing in concentrations not greater than that scarcely perceptible to the smell. Very weak concentrations, barely perceptible to the smell, have no ill effect but destroy the effect of unpleasant smell and give a certain tang or quality to stuffy air which relieves its monotony and un-

formity. It is in this respect that ozone has its use. The air in many buildings is made to smell by the heating appliance used. The addition of ozone takes away the smell and relieves the monotony of such air, and, as the Ozonair apparatus can, by the turning of a switch, be put in or out of use, the uniformity of the atmospheric conditions can thus be frequently changed. The ozone no doubt exerts its effect both on the cutaneous and respiratory nerves. There is no evidence that ozone reaches the blood, or that it has any other influence on the body. The effect which ozone in weak concentrations has on the olfactory nerves, and those of the skin and respiratory tract, is the justification for its use in ventilation.

An interesting discussion which followed the paper was published, together with the paper *in extenso*, in the issue of the "Journal of the Royal Society of Arts" for February 9th.

INDUSTRIAL EDUCATION AND EFFICIENCY.

The General Electric Company's Annual Dinner.

The annual dinners of the General Electric Company, Ltd., have attained more than a trade significance. The occasion partakes to a great extent of a representative function of the British electrical industry and Empire trade. At these gatherings there is usually an assemblage of some five hundred guests, embracing not only the best brains of the electrical profession, but also men of science, eminent statesmen, etc. The debates, which have always been a feature of these entertainments, possess an interest and an educational value everywhere recognised. This year's dinner, which was held at the Trocadero Restaurant, was no exception to the rule. Amongst nearly six hundred guests were: Sir George Houston Reid (High Commissioner for Australia), Sir Edward Holden, Bart., the Hon. Sir William Hall-Jones (High Commissioner for New Zealand), Sir William Bull, M.P., Lieut.-General Sir J. Bevan Edwards, Colonel Crompton, the Hon. Sir John McCall (Agent-General for Tasmania), the Hon. J. G. Jenkins (late Premier of South Australia), the Hon. Sir John Taverner (Agent-General for Victoria), Professor John Perry, the Hon. W. Pember Reeves (Director of the London School of Economics), Mr. Gordon Selfridge, Mr. A. J. Walter, K.C., Mr. Roger Wallace, K.C., Sir E. Grant-Burls, and Mr. Walter Reynolds, L.C.C.

Mr. H. Hirst, who presided, in proposing the toast of the evening, "Engineering Science and Industry," paid a warm tribute to the memory of the late Mr. G. Byng, chairman of the company, who died last year. Mr. Hirst referred to the great difficulty experienced by engineering firms in recruiting the best men to fill the important positions they have available. He said that engineers and all business houses were hampered by the fact that a business career was regarded at the universities as beneath the dignity of men of superior education and social standing. The majority of them rushed into the overcrowded professions of law, medicine, and journalism, and only turned to business when everything else failed. He considered it was important, not only for industrial houses, but for the welfare of the Empire, that university and public school men should

be encouraged to adopt a business career. Every civilised country was striving for industrial expansion to increase its capital and provide profitable employment for its people. All the nations of the world had formed themselves into so many industrial armies to compete for the industrial prizes the world had still to offer. He appealed to the powers that be at the ancient universities and seats of learning to see that Britain's industrial army of the future should be led by the best brains and best blood of the country. A university training was exactly the training required for modern business. Business to-day was no longer a mere matter of buying cheap and selling dear. The mere huckster was to-day out of place in a business concern. Business had gripped all the facilities science could place at its command, and the man at the head of it needed brains, grit, and culture in as high a degree as was demanded by any other walk of life. The world was rapidly changing, and the greatness of a country was no longer solely bound up with the names of great soldiers, great sailors, or great statesmen. When one spoke of the greatness of modern Germany, one's thoughts immediately turned to Krupp, Rathenau, Ballin, Koppel, and Auer. The greatness of the United States could not be properly defined without immediate reference to Morgan, Carnegie, Rockefeller, Westinghouse, Edison, Harriman, and other geniuses of industry and finance. In the same way England's greatness was inseparably bound up with the names of such men as Armstrong, Vickers, Harland and Wolff. The men who really counted to-day were those who, having built up great industries, found employment for hundreds and thousands of their fellow men, and thus added to the wealth of the nation and its fame all over the world.

Professor John Perry, who responded to the toast, said that the subject referred to by the chairman had occupied his thoughts for a considerable time. He urged, above all things, as the basis of scientific or commercial training, the cultivation in youth of the love of reading. He did not care whether a boy began with tales of Dick Turpin and pirates. Once the love of reading was implanted, it would grow until in the end the boy educated himself. He held a brief for the average boy.

Sir Edward H. Holden, Bart., who also responded to the toast, suggested that engineering firms should offer prizes to lads in their employment to encourage them to enter for and pass examinations at evening classes or technical schools.

Mr. Arthur J. Walter, K.C., considered that the suggestion raised by the chairman was one of extreme importance. He was a governor of two public schools, and he considered that the teaching staff was underpaid. The scholarship system, which trained for the best but not for the average intellect, was also largely responsible for the trouble.

Mr. E. G. Byng (vice-chairman of the General Electric Company, Ltd.), who proposed "The Parliaments of Empire," asked, what has the House of Commons done for industry during recent years? Industry had sacrificed many of her leading men to politics, and it was now time that the Commons reciprocated in a proper manner. He would like to see each Agent-General of our Overseas Dominions become an ex-officio member of the House of Lords, and recommended

the idea to His Majesty's Government as a means for instituting a truly Imperial Parliament.

Sir William Bull and Sir John Taverner responded.

Mr. M. J. Railing (director of the General Electric Co., Ltd.) proposed "Success to Imperial Trade." He referred to the fact that we often hear complaints as to lack of employment; but was not the remedy for this evil in our own hands? That England should foster her overseas markets was the keynote of his argument. "Let us extend our trade across the sea to our dominions." He looked forward to the day when the Empire would be controlled by one common Patent Law, when there shall be one common system of coinage and of weights and measures, and when there shall be a broader standardisation of educational principles. The presence of so many eminent statesmen and business men from all parts of the Empire testified to the keen interest they took in the development of trade with our dominions, and he hoped that our statesmen at home would endeavour to study likewise the requirements of our dominions abroad, as only by so doing could we hope to further increase and develop Imperial trade.

Subsequent speakers were Mr. Ellis T. Powell, Lieut.-General Sir J. Bevan Edwards, and Sir George Houston Reid.

Sir George Houston Reid (High Commissioner of the Commonwealth Government) said his own impression was that the children of England had never yet had half a chance. If the British Empire was to maintain its position, the children of the United Kingdom would not only have to be the equals of their ancestors, but would have to reach a point of efficiency beyond them. After all, trade and industry was nothing more nor less than a state of war: not war pushed to the extremity of bloodshed and loss of life, but war of skill with skill, contrivance with contrivance, management with management, finance with finance; and if all the battleships and all the British army were disbanded to-morrow, the problems of Empire would not be solved, but only begun. There was, however, one thing that all could do without waiting for Acts of Parliament—give a real preference to his own country. He looked forward to the time when all British manufactures would bear an imperial brand. "Made in Germany" was the best advertisement Germany ever got. It made people think there was something specially good about the brand of that article and that it was the real original thing. He would have liked to see all British-made goods marked "Made in the British Empire."

A Large Contract for Sewage Plant.

Messrs. Mather and Platt, Ltd., have just been instructed to proceed with a large contract for the Accrington and Church Outfall Sewerage Board, which comprised 24 of their pipe-arm type of revolving distributors, each 62 ft. diameter, complete with all appurtenances, as well as a sewage pump, screening mechanism, motors to drive the machines, and also the lighting work. Messrs. Mather and Platt, Ltd., are in a favourable position to undertake such contracts, as they are makers not only of spreaders, but also of pumps and electrical machinery, etc.

SOCIETIES AND INSTITUTIONS.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

A general meeting of this society was held on February 8th, the President, Mr. Sydney D. Kitson, in the chair, when Mr. E. Caldwell Spruce read a paper on "The Present-day Sculpture in France." The lecture was illustrated by many slides of modern works from the schools in Paris, Rodin's work being chiefly in evidence. In speaking of the realistic and emotional types so popular at the present time, Mr. Spruce expressed the opinion that such works, representing repulsive or disgusting subjects, should not be encouraged, as they violate in every way the mission of art. The lecture was concluded by a few comparative remarks on French and English sculpture and the respective attitudes of the French and English public towards the art.

SOCIETY OF ARCHITECTS.

The Fourth Ordinary Meeting of the Society of Architects for the Session 1911-12 was held at 28, Bedford Square, W.C., on February 8th, Mr. Percy B. Tubbs, F.R.I.B.A. (Vice-President), taking the chair in the unavoidable absence of the President.

Five nominations for Membership and fifteen for Studentship were announced.

The ballot was then taken, and the following candidates were declared to be duly elected for membership:—C. Chart, F.S.I., Croydon; W. G. Couldrey, Paignton; J. A. Dartnall, Leytonstone; J. P. Firth, Wakefield; W. H. G. Hubbard, Luton; R. Medcalf, Liverpool; T. B. Medcalf, Liverpool; G. Newton, Bournemouth; J. Thompson, Alderley Edge; L. S. Youngman, Bournemouth. For studentship:—J. S. Clutterbuck, Battersea Rise, S.W.; H. C. Low, Wimborne; H. Rhodes, Gorton; H. W. Sheffield, Earl's Barton; D. M. Wilson, Horsforth.

Mr. E. C. P. Monson, F.R.I.B.A., F.S.I. (vice-president), then read a paper on "The Housing of the Working Classes."

GUILD OF ARCHITECTS' ASSISTANTS.

In the annual report for 1910-11 of this Guild, it is recorded that the following proposals were made by the Guild to the R.I.B.A. and the Society of Architects for their consideration in framing the proposed Registration Bill: "(1) Registered practitioners to employ only registered men as assistants; (2) restriction of the number of pupils and unpaid assistants in a registered practitioner's office; (3) to legalise a scale of salaries for assistants, subject to approval of registration or other agreed authority; (4) that the general provisions of the Bill should offer greater security to the pupil by surveillance of his progress on request, and ease of appeal to the registration or other agreed authority by his parents or guardians when necessity demands; (5) that the present position of the assistant in relation to open competitions be retained." It is stated that this is the first occasion on which any definite proposals regarding the pupil and the assistant have been made to the two premier architectural societies. The report of a special committee appointed to enquire into the fixing of a scale of minimum salaries for architects' assistants is included. The necessity for a recognised scale of minimum salaries, the reporters observe, is to be found in the

constant tendency of salaries to decrease to absurdly low levels, quite inconsistent with material necessities. Analysis of a hundred cases, London and provincial, show average salaries of 21s., 31s., 49s. 3d., 61s. 8d., and 65s. for assistants ranging in age from 19 to 40 and over, the higher sums relating, of course, to the higher ages. The committee find no difference of salary between assistants possessing qualifications and those without them. It is further observed that "exceptional men and exceptional work will always find exceptional markets, and therefore are absolutely excluded from our consideration." The committee propose that the scale of minimum salaries for a week of 39 working hours shall be 25s., 35s., 50s., 65s., and 70s.—a scale that is not in excess of that observed by "the average conscientious practitioner." The hon. secretary of the Guild is Mr. Ernest J. Dixon, A.R.I.B.A., 137, Church Street, Edgware Road, W.

NEWS ITEMS.

London's New County Hall.

It is announced that the King, who will be accompanied by the Queen, will lay the foundation of the new County Hall on Saturday, March 9th.

The Junior Institution of Engineers.

In a booklet that has just been issued by this institution, dealing with "Its Origin and Aims," it is stated that the society was established in 1884. A copy of the booklet may be obtained free from 39, Victoria Street, Westminster.

Laying Out India's New Capital

The Liverpool Health Committee have decided to recommend the City Council to lend the City Engineer (Mr. J. A. Brodie) to the Government of India for the purpose of assisting in laying out the new capital of India. A request for his services came from the Under Secretary for India through the Lord Mayor (the Earl of Derby), who had given instructions for a special council meeting to be held to consider the matter.

Stained Glass Windows in Cardiff Coal Exchange.

In the extensions of the Coal and Shipping Exchange, Cardiff, some recesses on the north side of the hall are fitted up with stained glass windows, made by Mr. William Pearce, of Birmingham, from the designs of Mr. Edwin Seward, F.R.I.B.A.

Personal.

Mr. James Denver, Manchester, has been appointed secretary to the Manchester, Salford, and District Building Trades Employers' Association, in succession to the late Mr. John Tomlison. Mr. Denver entered the office of the late Mr. John Tomlison in 1900, has acted as secretarial assistant to that gentleman during his long illness, and succeeded him in several similar appointments.

Usher Hall.

Models have been submitted for the outside statuary of the Usher Hall. For the central doorway there is to be a design of the Edinburgh City Arms, supported by figures emblematic of music. Two subsidiary doors on the front, and the entrances on Grindlay Street, are also to be decorated with groups allegorical of music. The sculptors selected are: For

the central doorway, Mr. W. Birnie Rhind, R.S.A.; for the other front doors, Mr. McLure, of Kensington; for the Grindlay Street doors, Mr. H. Camley, A.R.S.A. For the organ, the organist of St. Mary's Cathedral has been asked to prepare plans and specifications, and six selected firms are to be invited to tender for its construction.

British Firms Secure Large Canadian Contracts.

A contract amounting to £1,500,000 has been secured by Messrs. Pethick Brothers, of Plymouth and London, from the Hudson Bay and Pacific Railway Development Company, for the construction of docks, granaries, station yard, buildings, etc., at Port Churchill Hudson Bay. Another contract amounting to a million and a half has been secured by Messrs. Norton, Griffiths, and Co., for the construction of harbour works at St. John's, New Brunswick.

Insurance against Accidents to Workmen.

It is stated that the Bradford City Architect's department is experiencing difficulties in securing compliance in some cases with the Corporation's requirements as to production by contractors of accident insurance policies, endorsed in the prescribed form by the insurance companies with a clause indemnifying the Corporation against any compensation they may be required to pay under the Workmen's Compensation Acts by reason of the death of or injury to any person employed in carrying out contracts for the Corporation. The sub-committee having charge of the department have therefore decided to recommend the insurance sub-committee to consider the advisability of making arrangements whereby the Corporation may be indemnified by a general insurance against all such risks.

Kempsey Church, Gloucestershire.

Mr. St. Clair Baddeley, of Castle Hale Painswick, Gloucestershire, ex-president of the Bristol and Gloucester Archaeological Society, is appealing for funds to rescue from ruin and restore to its use the little Norman church of St. Mary, Kempsey. It was built before 1121 A.D., and like the Chapel of St. John in the Tower retains intact its original barrel vault while its walls have preserved almost in their entirety the Norman paintings. The tower is in so perilous a state that it threatens to collapse, while the church throughout must also receive immediate attention. It is estimated that £1,000 will be required for this work, of which above £300 has already been procured. Donations will be received by the hon. treasurer, the Rev. C. L. Money-Kyrle Much Markle, Herefordshire.

The New Australian Government Offices

As announced last week, Sir George Reid, High Commissioner for Australia, has, with the concurrence of his Government, appointed Messrs. Marshall Mackenzie and Son architects for the Commonwealth offices to be erected on the Aldwych-Strand site. Mr. A. Marshall Mackenzie is an Associate of the Royal Scottish Academy, and a Fellow of the Royal Institute of British Architects. His achievements include the Marischal College and King's College, University of Aberdeen, the Waldorf Hotel, London, Kingseat Asylum, Aberdeenshire, Mar Lodge, Crathie Church, Balmoral, and Hursley Park, Hampshire. It is stated that Mr. Alfred Burr, F.R.I.B.A., will be associated with Messrs. Marshall Mackenzie and Son in the work.

The New British Museum and Its Neighbourhood.

THE new northern façade to the British Museum is a worthy architectural completion of the celebrated building. It does not, it is true, repeat the lavish expenditure of space in architectural effect which renders Smirke's southern façade so imposing to the architect and so wasteful in the eyes of the practical man who knows how much the museum requires more space to display its contents. "We might have all these colonnaded spaces inside," is the thought of the collector and curator, and how much more room they would have given." When the British Museum was built the extent of its future development was not imagined; but it was felt that it was an institution of importance and of high pretensions, and should have a frontispiece in keeping; hence this expenditure on portico and colonnades. The Greek style was uppermost in men's minds then; fortunately, for nothing could have been more suitable to a building which was to be the storehouse of such a collection of Egyptian, Assyrian, and (above all) of Greek antiquities. One could hardly say a Gothic British Museum. Mr. Burnet has not repeated the free colonnaded screens with a terrace behind them which are displayed on the south front; probably a more practical generation would have exclaimed against such a waste of space; but he has kept the architectural character of the south front in the finely proportioned order of engaged columns which adorns the north front, and by the severe and carefully considered detail of the whole. It is a really fine piece of work, and suitable to its position.

It is of some interest now to consider how the neighbourhood will be architecturally developed, to which the new British Museum gives the key-note. There has been a great amount of pulling about of old Bloomsbury recently, but fortunately Bedford Square has been left alone so far, except in the case of a foolish order, a good many years ago, compelling all the tenants, at great expense to themselves, to insert plate glass in the front windows, and is entirely spoiling the original character of the houses; but the whole character of Russell Square has been altered. Lower Street had been much despoiled of its original red brick style by the casing of the doorways with very commonplace stonework, on the west side, and now the east side is half demolished, and waste spaces behind the houses of the street are waiting for some new development. The best point to be seen at present in the new development of the Bedford estate is the provision of a fine wide avenue centrally with the new north front of the Museum introduced by continuing the line of Torrington Square right on to the British Museum. Torrington Square is one of those open spaces inaccurately called squares, because there is no other convenient name, but it is in fact a longitudinal place with a garden down the middle of it. It is a row for a square, but it is a splendid width for a road, "British Museum Avenue" is, or should become, a really fine addition to the list of first-class streets, if adequately treated. It appears that there is a proposal to make the two largest plots bordering each side of this street a site for new buildings for the University of London; a building containing a large meeting hall on one side; a

building containing the Senate House on the other side. This promises well; such buildings ought to be architecturally of the highest class, and if carried out they ought to be so designed as to group appropriately with the British Museum façade. Nothing could be more suitable than the neighbourhood of a University with a great place of study like the British Museum; and the architectural treatment should express this relation; the new architecture should take its keynote from the architecture of the Museum. There would in that case be the making here of a really fine and dignified architectural group. We should hope, if the scheme is proceeded with, to see an important architectural competition for the treatment of the buildings on each side of British Museum Avenue.

There are two other points that may be touched upon in connection with rebuilding in Bloomsbury. There has been a general tendency to the demolition of the ordinary sized dwelling-houses in these early nineteenth-century streets, always with the object of substituting larger and taller buildings. But one result of this is that the neighbourhood is getting, in a hygienic sense, overbuilt. Streets and neighbourhoods which do not appear overcrowded when the houses are of moderate height become overcrowded when much taller buildings are erected on the same sites, and with only the same width of street between them. Some attention ought to be paid to this on the Bedford estate; if taller buildings are to be continually erected whenever leases fall in and the site is set free, some attempt ought to be made at the same time to widen the streets and increase the distance between the buildings; otherwise the neighbourhood will, in a hygienic sense, be spoiled by the very means which are being taken to improve it.

SUGGESTED SITE FOR LONDON UNIVERSITY.

(From the "Times.")

Another detail that ought to be attended to is that the first opportunity should be taken to remove the return building which, in order to afford University College a new laboratory, has been erected along one half of what used to be the open quadrangle of the college. The college buildings were the work of Wilkins, in his day an architect of some distinction, and he never intended that any building should be erected that would close the quadrangle on the street side; he left no design for any such scheme; in his mind University College was to be erected round three sides only of the quadrangle, leaving the whole square open to view from the street. One plan of his exists, it is true, showing an open colonnaded screen along the street side, but never any buildings shutting in the quadrangle. By the building that has been erected, not only is Wilkins's design spoiled, but the commencement is made of shutting in from public view one of the few open spaces in a very crowded neighbourhood. The first opportunity should be taken of rectifying this aberration.

Village Architecture.

AN unspoiled English village makes a charming picture, in general, from the point of view of both the painter and the architect. The old cottages are built of the materials of the neighbourhood, and therefore harmonise with the landscape; they are built unostentatiously and with no pretence at the picturesque, in the way in which it best suited the local carpenter or mason of a former day to build them; consequently they have picturesqueness and character, qualities which come best when unsought. The village church shows a spire, or a small and unambitious square tower, rising almost always from among trees, and forming the culminating point of the whole group—

“A haunt of ancient Peace,”

as Tennyson happily expressed it.

It is not very often that one can find such an untouched village now, in its pristine simplicity; and it has been suggested in a weekly paper that one of the beneficent acts of the National Trust might be to purchase such a village and preserve it intact from any change or alteration, both as an object of contemplation and as an historic example of what the typical English village once was, before the days of railroads. It is suggested that now is the opportunity for such an enterprise; that old estates are being broken up and sold wholesale by owners unable to stand the strain of recent legislation; that such owners have a regard for the village that lies near their old manor-house, and would rather place it in the hands of the National Trust for preservation than sell it to a speculator. The implied conclusion is that the National Trust would get it on easy terms, and not be required to pay its market value.

The proposal is not entirely new in its nature; we have seen it suggested in print, for instance, that the leading European states should combine to purchase Venice, to keep it unspoiled as a unique city, such as will never exist again. One may well wish that such a purchase could have been made both of Venice and Florence, before the system of modernising had begun, which has spoiled Florence and is threatening to take the poetry out of Venice. But we rather doubt whether the scheme of purchasing a village and making an historic show of it (for that is what it comes to) would answer. The charm of its spontaneous character would somehow, it is to be feared, evaporate under the process. A model village erected in the grounds of an exhibition, to show what ancient English villages were like, we can understand; that would be confessedly a show and understood as such. To turn an actual village into a show place seems an unreal kind of proceeding, likely to defeat its own object.

Would it be more to the purpose to endeavour to keep the existing picturesque villages from being spoiled? The main influence in spoiling them lies in the desire to erect new buildings economically with materials brought from a distance. It is the increased means of cheap transit that does it. Before that came into being the stone of the dis-

trict was used; or if it were not a stone country, and timber was abundant, real “half-timber” cottages were built not sham timbers put into a brick wall and plastered up between, to look picturesque. Now, brick is brought by rail from the nearest brickfield, and the cottage roofed with corrugated iron, it is so cheap and durable. We remember coming on such an estate agent's cottage in the middle of one of the most romantic districts of Scotland. It seemed to blister the landscape. Take to the materials of the neighbourhood, and there will be an end of this ugliness.

Not all the characteristics of the ancient cottage should be revived, however. For one thing, its windows are much too small, either for light or healthful conditions of life. Oddly enough, this is just one of the undesirable points which are imitated in the cottages built for garden cities. Nearly always the windows are too small—because they once were, when people did not know better, and when there was the barbarous incubus of a window-tax. We ought to know better now.

And then there is not only the village architecture to be considered, but what we may call the village engineering. Have any of our readers been in the way of perusing constantly the reports furnished from time to time to the Local Government Board, by special medical visitors sent down to report on the causes of typhoid or some other disease in a rural neighbourhood? Nearly always the story is the same; want of proper water supply; water obtainable only from shallow wells, into which all kinds of impurities percolate; or got by dipping into streams polluted by surface water from farms; and even the questionable sources of water supply often are only available by going a quarter of a mile or so for them, and bringing the supply painfully home in such receptacles as are not too large and heavy for two of the children to carry. This is a constant story in the Local Government reports on the prevalence of disease. If an existing village were really purchased, according to the suggestion aforesaid, as an historic example, in most cases conditions like these would have to be preserved also, to show what were the hygienic conditions of the true ancient English country village. That might be a useful object-lesson for the generations to come, certainly, but not one very creditable to the present generation. And as to the class of hygienic conditions which may come under the general title of scavenging, it is best to shut our eyes to them, if we want to enjoy the picturesque.

On the whole, instead of purchasing an English village to preserve it in the annals of the picturesque, had we not better try to keep them as picturesque as before, and make them more healthy? The first object is best attained by using local materials and labour; the second by providing a proper water supply, and the means of removing pollution.

Water-Colour Paintings of the Old School.

THE annual exhibition of selected water-colour drawings at Messrs. Agnew's in Old Bond Street is an event of never-failing interest. The present is the fortieth of these exhibitions, in which we can see a collection of the works of the older water-colour artists of the English school, less brilliant than the modern school, but with more repose in composition and colour, and more simplicity and direct in their aims. In regard to some of them, it is true, one has rather to revise their former reputation. Copley Fielding, very popular in his day, is one of these; he cooked his effects rather, and his foregrounds, as in “On the Way to Firth Beacon,” are rather conventional in treatment. In an opposite direction, one can see that David Cox sometimes, as in the “Old Wooden Bridge,” rather overdid his “blottesque” manner of working, but “Bettws-y-Coed Churchyard,” a drawing which has emerged at many water-colour exhibitions, is a masterpiece of brush-work. A good many of the early topographical drawings of Turner, those of the date 1800 and thereabouts, are here, and are very interesting. “We

Cathedral," a rather large drawing of the west front, painted in 1802, shows how well and solidly Turner could paint Gothic architecture at that date. By Turner's predecessor, Girtin, is a little masterpiece, "The White House, Chelsea Reach," the very small white house forming the one bright spot of light in the composition. His view of Southwell Minster is interesting historically, as it shows that at the time he painted it the square pyramidal slated spires over the western towers were standing; they must have failed or been removed since his time, as they formed part of the modern restoration work; they have been restored with much less projection at the base than is shown in Girtin's drawing, but look better so. There are plenty of fine examples of Prout's solid and learned drawing of mediæval architecture. Prout did not see as much colour in old stonework as modern artists see; to him old masonry was mostly in various shades of brown; he depended on the living figures introduced for the element of bright colour; possibly his view of the facts about ancient masonry was more correct than that of the modern artists who read all kinds of colour into it. Prout was a mannerist, of course; but it is a very fine manner, and few men have painted architecture so well. Another old water-colour artist who dealt only in architecture was James Holland, who loved not, like Prout, the brown stone of mediæval cathedrals, but the marble and colour of Venice; his drawing of the Rialto is a good example of his art. Compared with these two, Read's Interior of Münster Cathedral is merely what may be called architectural drawing; hard and correct as such, but not a picture in the true sense. David Roberts appears, too, among the painters of architecture; his delicate little drawing of the temple of Kalabstré is unlike his usual style, and somehow suggests the work of Mr. Albert Goodwin. Among the landscape pictures none here are so fine as Collier's, an artist of the rather later period, who may be said to be an artistic descendant of David Cox, but one who surpassed is master; keeping to a broad and true water-colour style, but never becoming, as Cox sometimes became, ragged and untidy in execution. He perhaps shows best that the older school of water-colour could accomplish.

Mural Paintings for Schools.

A COMMITTEE has been formed for promoting an exhibition, in May next, at the Crosby Hall, Chelsea, for the encouragement of the decoration of schools and other public buildings by mural paintings; but we should rather from the announcement that the decoration of schools is the main object, as one part of the exhibition is to be devoted to "designs by architects for the disposition of schoolroom fittings in combination with mural decoration." When the exhibition opens we shall be able to see what the proposal has produced, and in what direction it is tending. In the meantime it may be suggested that perhaps the ideas which have prevailed as to mural paintings in schools need some reconsideration. Various colour-printed designs, by Mr. Heywood Sumner and other able artists, were produced some years ago, with the view of their serving as mural decorations to schools, either by being hung up or being otherwise affixed more permanently to the walls. These met, we believe, with some acceptance, but it may be questioned whether they were quite the right kind of thing for the purpose. A good many of them included what are evidently regarded as decorative landscapes, only a little more "decorative"—i.e., much further removed from actualities of nature than usual. Decorative landscape is a possible form of art, as the French have discovered; it means with them landscapes which are like nature as far as they go, but which omit a good deal of detail, select only simple lines of composition, and avoid ocular deception as to effects of distance. Such landscapes can be painted on a wall without strongly contradicting the impression that it is a flat surface; examples of them, sometimes by distinguished painters, may be seen in almost every artist's exhibition at the Salon. But the mural subjects for schools, just referred to, went a good deal further than this.

They represented not so much decorative landscapes as symbols of landscape, treated much as landscape is sometimes treated (but never should be) in stained glass; flat tints divided off by strong dark lines; a red circle representing the sun, rising from behind a green curve representing the undulation of the landscape; and so on. Now, it may be doubted whether children either understand or enjoy this kind of production. They cannot be expected, of course, to understand anything about conventional treatment for a mural plane; all they know is that they see a painting which is supposed to represent a scene in nature, but which is quite unlike anything they themselves see in nature. As far as landscape subjects are concerned, they would be better pleased and better instructed by framed pictures of landscape hung on the walls. This, it may be replied, is not mural painting; but it is something which, as far as landscape is concerned, is a good deal better. Even the higher class of decorative landscape as practised by the French artists would not appeal much to the infant mind; it requires a good deal of education in art to understand it. It would be far more instructive and probably more interesting to children, to have a series of framed representations of celebrated towns or scenes, hung on the walls. They would then realise that, without being able to travel like the richer folk, they had got some knowledge of what different distant places looked like. That cannot be done with mural painting, because the real places do not look like that.

We should be very glad to see decorative mural painting practised and encouraged in schools, but not in the form of attempts at landscape. What ought rather to be encouraged is the representation of historical scenes and personages; that is, figure painting representing great characters and actions. These can be made intelligible in a style suited to mural painting. Mr. Walter Crane, speaking at the meeting referred to, said he was greatly in favour of symbolical and allegorical subjects, "as they were most likely to impress the young mind." He may be right; we should be glad to think he was, for undoubtedly that class of subjects is the most suitable of all for decorative mural painting. But that subjects of that class impress the children of the poor (or the parents either, for that matter) seems rather doubtful. They do not get at the symbolical meaning. A mosaic copy of Watts's "Time, Death, and Judgment" was produced, a good many years ago, on the wall of an East-end church; may be there still, for all we know. The remarks of the local bystanders, when it was unveiled, showed that they had not the remotest notion of the object or intent of such a work. One good woman, pointing to the half-length nude figure of "Time," said: "I suppose that will be her Majesty the Queen." However, each generation of Board-school children is probably a little better educated than the last, and perhaps the symbolical style may be worth trying for paintings in schools. It would certainly be gratifying if it succeeded, both from the educational and the artistic point of view.

Smaller Class-rooms.

THE long-standing disagreement between the Board of Education and the London County Council as to the size of classes in elementary schools having been virtually determined, the Council now finds itself obliged to do compulsorily what it ought to have done years ago with a good will. It is recommended that the Education Committee shall prepare a scheme providing for the reduction of the number in a senior-school class to 40, and that of an infant-school class to 48. This change from classes of about twice the accommodation indicated will necessitate heavy expenditure on the necessary structural alterations in existing schools, and, of course, considerable modification in the planning of new ones. The Council are asking for a period of fifteen years in which to effect the reform! and it is estimated that the sites and buildings programme for that period will involve an expenditure of £4,500,000 sterling. It is good to look ahead, but why push the principle to so ridiculous an extreme?

THE OPEN-AIR LIVING-ROOM OR LOGGIA.

BY C. E. MALLOWS, F.R.I.B.A.

AT the present day, when so much care and attention is being devoted to hygienic considerations of living, it is a matter for no little surprise that such a pleasant and health-giving feature as an open-air living-room does not appear as a usual and an accepted provision in a modern plan of house and garden.

The objection it usually meets with is that, in this changeable and uncertain climate, it can only be serviceable for a few days in the middle of summer, and that for the rest of the year it is so much waste space. It is quite true that unless very careful attention is given to the planning of the room, to its accessibility, to its right relation to the rest of the house, to sunshine and prevailing winds, it can easily fall short of success; but with care and forethought the open-air room can be made not only a very desirable and practical part of the house plan, but one of the most delightful and

Another plan which has sometimes been tried, and which also falls short of success, is to place the loggia directly accessible to the service but detached from the house, and approached by a paved way or pergola. This method, although a great improvement on the one just described, as food may be served hot in the latter, is still almost sure to fail of its purpose for the greater part of the year, because of the necessity of crossing an open space unprotected from the weather, a necessity which is not always an inviting prelude to meals.

The open-air room to be quite successful as a matter of plan must communicate immediately with the dining-room (it is best with no intervening lobby or space of any kind), and should be quite close to the service door in that room. It should form a kind of annexe there, and should be so placed in relation to it that the service crosses are at the corner or end of the dining-room only, leaving the rest free for undisturbed use as a reading or writing-room. Perhaps there are few better positions than the north-east angle of the dining-room, and, externally, at a re-entering angle formed by the wall of the main part of the house

DESIGN FOR AN OPEN-AIR LIVING-ROOM IN A MONMOUTHSHIRE HOUSE. C. E. MALLOWS, F.R.I.B.A., ARCHITECT

attractive links between the garden and the house. It can, indeed, be made to add very greatly to the artistic charm and interest of both, and, by a little thoughtful contrivance, the plan of the garden can be brought, by means of this loggia, actually into the house plan by a delightful gradation between the two, securing from house and garden most pleasant effects of light and shade and framing, from the house, interesting pictures of the garden.

From the practical point of view, and therefore the all-important one, the greatest care is undoubtedly necessary to meet the objection stated above, and one of the first considerations should be the placing of the loggia in relation to the kitchen and dining-room. It should rarely, if ever, be detached from the house itself. If it is treated as a detached building altogether, with no covered connecting way to the house; if it is placed (as it sometimes is) at the end of a terrace, although it may form an attractive ornament in the garden, its practical use in all probability will be for an occasional afternoon tea in midsummer and for the rest of the year as a receptacle for all kinds of odds and ends, garden chairs and tables—a sort of auxiliary garden store, which is not precisely the end to aim at, but which is the actual end to which some of these otherwise admirably designed rooms have been known to descend.

extending southwards, and a line of outbuildings or high wall extending eastwards. In this position, with an open stone-paved terrace on the east side, for use in the evenings of a summer such as last year, when coolness and fresh air are welcome and no shelter is desired, the open-air room or loggia invites use not only in the dog-days but on many a bright morning and evening of early spring and late autumn.

In such a plan as that just indicated, the north side of the room would be formed by the wall of the outbuildings or adjoining garden, the east side would be open—treated either as an archway or by piers forming wide openings—the south side would be similarly treated, and the west side would be occupied by a wide door or two or three small ones glazed nearly to floor level, so that the full effect of the garden seen from the dining-room through the shade of the loggia could be obtained. The open spaces on the south and east sides would have movable screens for use when weather conditions made some such protection necessary. The size of such a loggia would be from about 16 to 18 ft square and longer (but not wider), according to the size of the house and the needs of its inmates.

A loggia of these dimensions would, of course, be suitable for a fairly large house, and might perhaps be called a luxury entailing an outlay which luxuries usually involve.

A HOUSE IN A MONMOUTHSHIRE VILLAGE. C. E. MALLOWS, F.R.I.B.A., ARCHITECT.

The problem is a different one when connected with smaller houses, and one not quite so easy of solution, particularly when an additional condition is laid down to the effect that the open-air room, whilst fulfilling at times its primary purpose, should also be capable of being used in other ways, thus securing economy of space in the house plan.

Such a condition formed part of the requirements of the small scheme for a thatched cottage here illustrated—in addition to an old four-roomed cottage shown on the right hand of the perspective sketch. In this plan the wide corridor between the hall and living-room forms the open-air room when required, either complete in itself as such, or by opening the glazed doors on either side, or as part of the dining-room, which in this way can be added to the loggia, and both spaces together be formed into one large room entirely open on the south side to the garden and the fresh air, being screened. It is on both sides, by the projecting wings of the little parlour on one side and the living-room on the other. With this arrangement of double-glazed doors on each side of the corridor (which is 7 ft. wide) the advantages obtained are obvious.

In the hottest weather all the doors can be opened wide; in cooler weather the sides can be closed; and in winter time, or when open-air living is quite impossible, the corridor forms an effective bar to the dining-room against the cold; yet with the windows glazed nearly to the floor line the full benefit of the garden picture, with its small paved court as a foreground and the glimpse of the distant country beyond, is always obtained.

In the planning of loggias or open-air rooms to smaller houses—for houses costing, say, from £500 to £3,000—the first consideration, after the conditions mentioned above have been complied with, is naturally one of size. Unless this point is very carefully considered, the provision of such a space will be useless. Many such rooms have been foredoomed to failure from the first because when the necessary table has been placed in it no room could be found for the equally necessary chairs. The width has oftentimes been sacrificed for a wholly unnecessary length in order to obtain breadth of another kind, in external effect. Probably the best seating arrangement for a loggia is that

A HOUSE IN A MONMOUTHSHIRE VILLAGE. C. E. MALLOWS, F.R.I.B.A., ARCHITECT.

A HOUSE IN A MONMOUTHSHIRE VILLAGE: DETAIL OF WINDOWS TO OPEN-AIR LIVING-ROOM. C. E. MALLOWS, F.R.I.B.A., ARCHITECT.

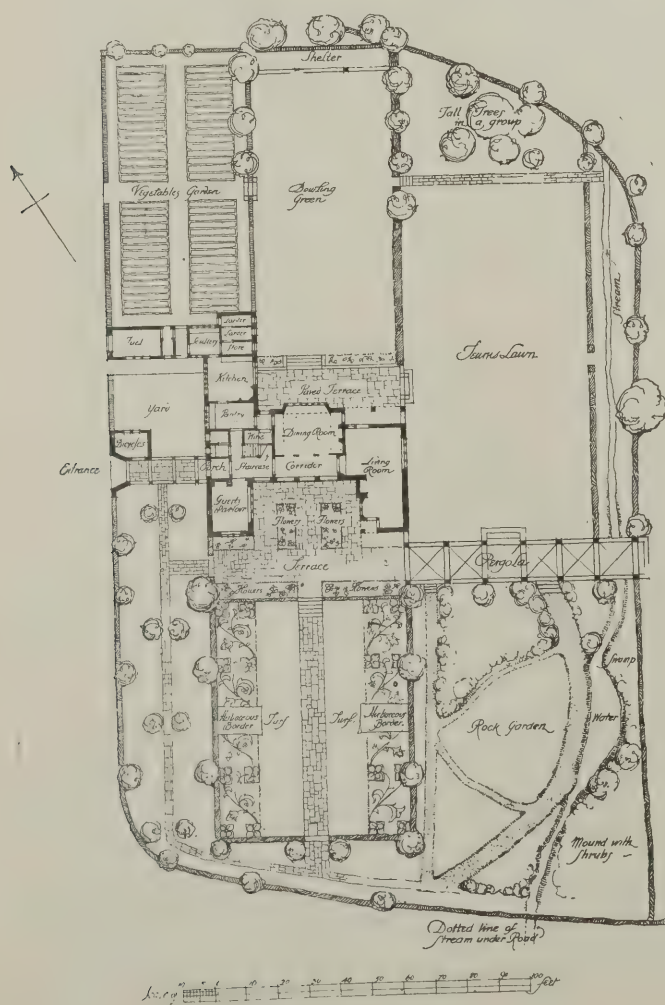

obtained by placing a row of chairs next the walled part or back, and using a long and narrow table, about 2 ft. wide, with a seat at each end. The garden side of the table would thus be free, and those seated at the table, on three sides of it only, would be enabled to enjoy an uninterrupted sight of the garden pictures. If such an arrangement of chairs and tables is set out to scale on paper it will be found that a width of 7 ft. is the very least admissible if good shelter is to be obtained and the service to the table free of discomforts and possible disasters!

This width, as just suggested, allows for one row of chairs and a narrow table; a wider table and a double row of chairs would mean a minimum width of 10 ft. But the former plan is obviously the better one in every respect, and is certainly much handier for the table service. The

position of the loggia in the plan will, of course, be governed by the nature of the site, its aspect and prospect—each problem must be settled on its own merits; but as a general rule it is well to secure an approach from the north or north-east side of the dining-room and to obtain shelter in a re-entering angle, as described in the larger scheme.

COPYRIGHT IN ARCHITECTURAL DESIGN.

A CURIOUS case of the intervention of the law in France, in protection of an architect's copyright in his design for a building, is recorded in the issue of the R.I.B.A. *Journal* for February 10th. It is curious because the facts are unusually clear and simple, and the judgment of the Court, on the contrary, is rather vague and self-contradictory. The plaintiff, as we should call him in England, was an architect, M. Lenoir, who discovered at Royan a building, the Amiot Private Hospital, which was a copy of the casino built from his designs at Gourmalon. That the façade of a casino should be copied for a hospital building seems rather odd, but the fact was considered by the Court as fully established; and as French architects have, and not infrequently adopt, the right of placing their names on the buildings erected by them, M. Bureau, the plagiarist architect, was ordered to remove his name from the hospital building, and to substitute the words, "built from the design of M. Lenoir." So far it is all plain sailing; but the further judgment of the French Court is rather difficult to make logic of. The Court inflicted on the plagiarist architect the modest fine of £2 (500 francs) only, and proceeded to draw a distinction between the case of an architect and that of a sculptor or painter. In the case of the latter, it is said, the material damage caused to the artist or the purchaser of the work is equal to the profit resulting from the sale of each object reproduced; but this, it is argued, "cannot be the same as the case of an architect, who not only sells to his client his plans and designs, but deprives himself besides of the right to build a second house similar to the first for a third person without the consent of the owner, unless otherwise agreed." Thus, it is argued, "the architect suffers on moral damage as the result of the work which he has created being wrongly attributed to a plagiarist"; and moral damage seems to be assessed at the value of £20. Mr. John V. Simpson, who quotes the case in the *Institute Journal*, comments: "If the architect had parted with his copyright, it would not be he, but the owner of the building, who would be aggrieved by the piracy. If he had not parted with it, he had certainly not deprived himself of the right referred to." That certainly seems quite clear; but the case is another point of comparison between the architect on the one hand and the painter or sculptor on the other. Does a painter or a sculptor, when he has sold a special work to one purchaser, consider himself at liberty to produce an exactly similar replica of it for another person? So, as we understand it, the law would not prevent his doing so; but it would hardly be considered a very fair proceeding, and would be apt to injure the reputation of the artist. Surely the same reasoning applies to an architect if he has retained his copyright, he has the same legal right to erect an exactly similar building for another client, but he would probably be restrained from doing so by the same considerations which would affect the sculptor. If, therefore, he only receives "moral damage" from plagiarism, it is surely the same with the sculptor; there is no ground for putting them in different categories. The moral damage, to an artist of any description, is surely worth something more than the modest sum at which the French Court assessed it. The case seems to have been a gross and quite indefensible one, for which the offending architect has got off very easily. It would be regrettable if it should be accepted as a precedent in England, where, in spite of the new Act, there is only too much disposition to regard an architect as a person who has no rights on the same footing as other artists.

RESIDENTIAL COLLEGES.*

BY EDWARD WARREN, F.S.A., F.R.I.B.A.

The greater portion of Mr. Warren's paper was devoted to a discussion of the origin of collegiate institutions, with descriptions of many of the earlier foundations. Of more immediate practical interest were his personal observations on the details of college planning, and it is to these that chief attention is here given.

I SPEAK entirely of residential colleges, embodying the accepted ancient features of chapel, hall, kitchen and offices, master's dwelling, common room, and fellows' and undergraduates' rooms, as well as the modern requirements of lecture-rooms and bursaries, and those concessions to modern habits and ideas, the common-room, smoking-room, the junior common-room, and last, and most recent, bathrooms. If you adopt the quadrangular plan, and I think that you cannot, generally speaking, do better on all accounts, you will be wise, unless the ground and other circumstances permit of large courts with low surrounding buildings, to remember Dr. Caius and the open front to the south, or else to have open corners which can be bridged by arches, to admit of air currents, or "perspiration," to use Dr. Caius's own term. Such open corners can be easily and effectively managed if you adopt the cloister ground plans with arcade or colonnade, and this in itself is a practical and architecturally admirable arrangement.

Or you can perhaps find useful suggestions in the double-screened or pierced ground storey of Peterhouse. I am assuming that you adhere to the healthy and invigorating system of passage-ways open to the air.

As the plan of repeated staircases, with their dependent groups of rooms on each successive floor, still finds, and is likely still to find, favour in colleges, it may be well for a moment to consider some of its possibilities, and, to that end, the author showed a plan of Brasenose College, in which were seen the arrangement of the old chambers, and Mr. T. G. Jackson's disposition of the new. But if you arcade your ground floor, you must, of course, narrow the depth on that floor available for rooms, and will probably find that lecture-rooms, bursaries, single rooms for non-resident tutors, or single sets, can best be placed there.

Mr. Lock has pointed out that the arrangement of two sets in depth with the dividing wall has two disadvantages—(1) you lose the opportunity of free air passage, or perfilation, so easily obtainable if you have single sets of sitting or "keeping" room and bedroom, in the depth, by means of the usual communicating doors; (2) both bed and sitting rooms must have the same aspect. There is a further disadvantage, which is that as your span increases your roof is apt to grow higher, and it is generally desirable to keep it down. If bathrooms are supplied, and with a sufficient number of baths, the bedrooms can be very small—say about 100 square ft., or even slightly less, but of course a comfortable bed space, not facing the light, should be provided. Bathrooms are very generally placed in the basement, and this where ground floor is raised a little, so that the window-heads can be brought slightly above ground, does very well, provided that the necessary areas for light and ventilation can be outside the quad-

rangle—that is, at the back of the ranges, and wide enough, and that smaller areas or fresh-air inlets are provided in the quad, so as to give a cross current. The baths are generally arranged in cubicles some 7 ft. by 5 ft., with partitions 6 ft. high or thereabouts, and raised well off the floors, in the ratio of a bath to four or five men, and about half the number of shower-baths. A service room for keeping and drying towels, and a general dressing-room, or two, for muddy youths fresh from "Rugger" or "Soccer," is most advisable, with a supply of lockers for flannels, etc. If you have a bathroom and consequent bath boiler, somewhere in the basement, a hot-water supply to each pantry can be arranged. The Fellows' rooms are usually now in sets of three, a large sitting or tutorial room, a smaller sitting-room, and a bedroom, and should have an "oak." College bursaries are merely offices for college business, and should be conveniently placed near the entrance. There must be at least two good well-lit rooms, the bursars' and bursary clerks', and a strong room and lavatory. Frequently more rooms are needed, a senior and a junior bursars' rooms, and a college office or meeting room.

The master's dwelling has grown from the few rooms formerly allotted to celibate masters, and is now a complete domestic dwelling for a married man. It is much like a good rectory house in requirements, but with one special need, a really large study or library, with an ante-room leading to it. The dining-room should also be a large-room.

The common room has expanded from the ancient parlour or solar, into a group of rooms constituting the Fellows' private club, and having a large and comfortable sitting-room, where dessert, wine, and coffee are taken after dinner in hall, and where luncheons are generally served. Attached to, or near, this is the now invariable smoking-room, and it is not infrequent to have a third and smaller room for writing, etc. The junior common room is the undergraduates' club, and usually consists of one large room, where breakfast, and frequently luncheon also, is served. It is useful to provide a second room for reading, writing, etc., and for both senior and junior common-room groups a distinct lavatory is advisable. There is a new refinement of the common-room group which I have just been called upon to supply at Oxford—that is, a common-room dining-room, with an ante- or drawing-room leading to it, and a cloak-room and lavatory. This is for the private or collective hospitalities of members of common-room, and completes the club. I have not yet heard of a demand for billiard-rooms at the universities, but have met with that requirement in the masters' common-room of a large public school.

Residential colleges for women are multiplying and extending, and growing in architectural importance and beauty. These naturally require somewhat different arrangements, the general system, being more domestic, and open-air pas-

sages and basement bathrooms, etc. being usually avoided. Large bed-sitting, rooms usually take the place of the masculine double set, but parlours and music and recreation-rooms are provided. Otherwise the recognised collegiate requirements apply, the chapel, hall, and library being just as essential as for the other sex. Bursaries, perhaps, are not so formal, and common-rooms have a rather different character, being, for one thing, connected more with tea than the grape. I have not yet heard of any demand in a ladies' college for a common-room smoking-room, senior or junior, but it may come. Girton College by Mr. Alfred Waterhouse and Newnham by Mr. Champneys, at Cambridge; Somerville partly by Mr. Champneys, Lady Margaret Hall by Professor Blomfield, at Oxford, and Holloway College in Surrey, are among the best known, but Mr. Champneys is now adding to the number Bedford College in Regent's Park.

Chapels.

The chapel of a college is traditionally a chancel, screened off from the ante-chapel, to which the non-collegiate are admitted, and is the survival of the monastic choir screened from the secular nave. The seats are arranged as stalls, looking inwards instead of eastward, as in secular churches. Return stalls are allotted to the master or president, and his more immediate satellites. The seats are ranged in tiers rising from the gangway, the Fellows occupying the upper and more dignified rows, the undergraduates the inner and lower. There is usually no pulpit, as sermons are only occasional, and are delivered from the lectern. The organ and choir gallery are very usually placed on top of the screen. A college chapel, if of greater height than adjacent ranges of the building, and placed axially more or less east and west, should, if on the side of a quadrangle, be always on the north side, so as not to cast its shadows where shadow is detrimental.

The chapel is the better without any east window as a rule, and chapel and hall alike are the better for uninterrupted ranges of side windows, which are best kept high, in the first case, on account of the stalls and their panelled backs, in the second to avoid a low light in the diners' faces, and to provide the opportunity of a high wainscoting, which is incidentally an admirable background for college portraits.

In planning a non-residential college, —say the modern University college of a large town, and intended, of course, for both sexes—the problem becomes very different. The chapel is usually not required, the hall subserves different purposes, and is usually more or less of a speech hall; lecture-rooms, lecture theatres, and class-rooms, scientific laboratories, and workshops are needed, and not infrequently some sort of museum is added, and a gymnasium is not unheard of. Colleges, residential and non-residential, have been devised and built in recent years in considerable numbers, and it is interesting to observe in what manner the collegiate sense has been accepted or interpreted by those to whom it has fallen in recent years, either at Oxford or Cambridge, in immediate contact with these ancient things, or elsewhere free from such propinquity, to build colleges or schools, of collegiate type. As example, of such buildings, the author cited Keble College (Mr. Butterfield), Mansfield (Mr. Champneys), Hertford (Mr. T. G. Jackson), additions to Trinity and Brasenose (Mr.

*Extracts from a paper read before the Royal Institute of British Architects, February 19th.

T. G. Jackson), quadrangle of St. Swithun at Magdalen, and President's lodgings to that college (Messrs. Bodley and Garner), the L-shaped beginning of a court to King's, Cambridge (Mr. Bodley), lodge court to Pembroke (Mr. G. G. Scott). Sir Aston Webb and Mr. Ingress Bell have recently built a new court, that of St. Michael's for Caius College, faced in fine stone ashlar, and most ingeniously and adroitly planned. The same architects have been responsible for much collegiate work in many places, notably at Birmingham University, the Science College in London, and in the fine and comprehensive scheme of the new Christ's Hospital at Horsham. Mr. H. T. Hare has designed for Cambridge a Non-conformist theological college, for Presbyterian graduates, known as Westminster College, in brick and stone, the forerunner of his greater and more striking collegiate opportunity in the North Wales University College at Bangor.

DISCUSSION.

Mr. Basil Champneys, proposing a vote of thanks, said he had long been puzzled as to how the standing arrangement of staircases in colleges first came into being. The whole arrangement seemed to be without a hint of precedent. Introduced by William of Wykeham, it had ever since held its own, and no better method had been devised up to the present day. Referring to the corridor arrangement of plans for colleges, the speaker said that one of its great disadvantages was the difficulty of providing adequate lighting. In colleges for women, however, this type of plan was obviously the best. Another difficulty encountered was the predominance of science in modern universities. To satisfy all the requirements in this connection caused a good deal of trouble.

Professor F. M. Simpson, seconding the vote of thanks, recalled that the University of Paris was the first to bring the college system into favour. Paris was said to have had fifty colleges of its own; how was it they had ceased to exist? He thought it was largely owing to the state of the country at the end of the sixteenth century. In consequence of the civil war and other influences, towards the end of the sixteenth and at the beginning of the seventeenth century, it was recorded that the colleges of Paris were practically empty. England, in the sixteenth century, had similar difficulties which, however, resulted, not in civil war, but in the Reformation. The Reformation was responsible for the clearing-out of the great bulk of the students; but with the Reformation came the Renaissance, filling those colleges again with another set of students. In Paris, of course, the colleges belonged to the clerical party, and were not confiscated as they were in England. Continuing, the speaker regretted that Mr. Warren had not included the big buildings for scientific research. The requirements for a modern laboratory were large windows, lofty rooms, and walling reduced to a minimum. The old buildings, while charming in themselves, were unsuitable by reason of their small windows. A scientist would say that the three primary requirements of a modern laboratory were (1) light, (2) more light, and (3) still more light.

The Rev. J. B. Lock, M.A., Professor at Caius College, Cambridge, referring to the question raised by Mr. Champneys, advanced a theory concerning the origin of the college plan. Queens' College, he said, was almost an exact replica of

Haddon Hall; in both cases there were two courts, a gallery in the same position, and a chapel on the north side of the quadrangle. The only difference was found in the position of the kitchen. Mr. Warren, he continued, had made no reference to his restoration work at his (the speaker's) own college, where, among other works, the lecturer had erected a screen, converting what had been a very bare interior into a splendid mediæval hall. With regard to the desirability of having one side of a court open, Mr. T. G. Jackson had provided a solution of the difficulty in his Law Library and Sedgwick Museum by erecting the library on the top of arches, thus ensuring a current of fresh air from one side of the court to the other.

Mr. T. G. Jackson, R.A., said that the college plan had grown up insensibly without any definite motive at first. The universities were never founded. Nobody founded Oxford or Cambridge; they grew up in an accidental way. Originally, for about 200 or 300 years, there were no colleges at all, the universities existing without them. Brasenose Hall, he continued, was so named after a huge door knocker, long before the college itself existed. These houses, which then constituted the University buildings, were of the ordinary domestic kind. Two or three were subsequently thrown together, and therein they would find the origin of the college type. More of these houses were gradually swallowed up and formed into one college. The original colleges, therefore, before the existing buildings, would have looked like a number of houses in a street, each having its own independent stairway. This, he thought, was beyond all doubt the origin of the universities.

Mr. Aymer Vallance having spoken (illustrating his remarks with a few slides),

Mr. Warren briefly replied.

SOCIETIES AND INSTITUTIONS.

YORK AND YORKSHIRE ARCHITECTURAL SOCIETY.

Lecture on San Micheli.

A lecture by Mr. J. Stuart Syme, Lic.R.I.B.A., was delivered on February 14th before the above society on "The Life and Work of Michele San Micheli," Mr. A. B. Burleigh, Lic.R.I.B.A., being in the chair.

In the course of his remarks, the lecturer said that a study of the life of San Micheli is interesting, not only on account of the distinctive qualities of his work, but also on account of his position in perhaps the most important period of the Italian Renaissance. Born in 1484, the son of an architect, brought up in an architectural atmosphere, sent to Rome at the age of 16, to study for his profession, he developed into a genuine architect, in contradistinction to some of the other masters, who bestowed part of their allegiance on the other arts of sculpture and painting. Nor is it surprising that his work appears to have certain architectonic qualities lacking to some extent in the works of his contemporaries.

The most famous architect practising during San Micheli's youth was Bramante, who was engaged during the early part of it in Lombardy, not so very far from Verona, and during the later years in Rome. In fact, the youth and the

master went to Rome about the same time—namely, about the year 1500—Bramante to engage in the work of the Cancellaria and Giraud Palaces, and the youth, we can hardly doubt, to seek inspiration equally from new and old work, the practice then as it is to-day. We may be pardoned, therefore, for supposing that San Micheli came under Bramante's influence; and there is something to support this in the similarity of the façades of the churches of Santa Maria in Organo at Verona and San Satiro at Milan, not to mention other points of similarity in various window and other details.

San Micheli's greatest claim to fame arises out of his military architecture. His first direct connection with such work appears to have occurred when he was about 30 years of age, and within a few years he had effected a revolution in the design of permanent fortifications, the importance of which entitles him to rank with Vauban among the greatest of military engineers of all time. This work was the invention of a new type of bastion, whose front was angular, the apex towards the attack, and the subtending sides when produced cutting the line of the curtain outside the bastion and at points more or less remote from it as circumstances directed. The new arrangement permitted the faces of the bastion to be completely swept by fire from the curtain, and also to some extent from the adjoining bastions. This was impossible with the square and circular towers in use previously, and, combined with the other new features the designs presented, was of enormous advantage to the defence. It should be pointed out that Viollet-le-Duc has disputed San Micheli's claim to this honour, in favour of some unknown French engineer, but his evidence is by no means conclusive. San Micheli seems to have been engaged almost exclusively in fortification work for a number of years, and there can be little doubt that this experience, which involved a careful consideration of questions of utility and sound construction, greatly influenced him when called upon to design works of a more decorative and architectural character.

Two of his finest buildings are the Porta Nuova and Porto del Palio at Verona, both designed with remarkable simplicity and directness. He also designed four fine palaces in Verona, of which the Pompeo and Bevilacqua are the most notable, and the Grimani Palace at Venice, the perfection of whose lower storey is somewhat marred by the faulty proportion of the upper stages, for which it is possible that San Micheli was not responsible. He made several designs for churches, but, unfortunately, few of them were carried into execution, and even these were not completed in the author's lifetime. As a designer he was gifted with considerable facility, which he exercised with the greatest refinement and restraint. His work, while sound both constructionally and artistically, is never dull, and does not lack originality. If we may believe Vasari, the character of the man was in keeping with his work and would justify one in regarding the study of his life and art as well worth the attention of the thoughtful member of his profession.

The following officers for the present session have been elected: President Mr. A. B. Burleigh, Lic.R.I.B.A. vice-presidents, Mr. T. W. Whipp, A.R.I.B.A., and Mr. J. H. Rutherford, Lic.R.I.B.A.; hon. treasurer, Mr. J. D.

TRADE AND CRAFT.

Claridge's Patent Asphalte.

Although Claridge's Patent Asphalte Company was established so long ago as 1838, and must, in the period of nearly seventy-four years that has since elapsed, have done a vast amount of work, besides circulating a good deal of information on the subject, it seems that there are still very many "men who build" who are but imperfectly acquainted with the properties and uses of the material. Those who acknowledge themselves to be in this position, as well as others who fancy that they know all about a material that has been for so long in such general use, should procure the pamphlet "On the Uses and Fireproof Properties of Claridge's Patent Asphalte, with a list of the purposes to which it may be advantageously applied, and Suitable Thicknesses," which has been issued by Claridge's Patent Asphalte Co., Ltd., Victoria Embankment, W.C., and Pyrimont Wharf, Cubitt Town, E. It contains reports of experiments, and of results of fires, affording convincing proof of the fireproof properties of Claridge's asphalte when used in construction, descriptions of roofs, flooring and paving, damp-coursing, reservoirs, and many other applications of the material; and a series of illustrations (usually in section) of various forms of construction in which this asphalte is employed; the descriptive matter being in each case succinct and practical. Claridge's Pyrimont Seyssel asphalte has been largely employed in the construction of fireproof floors, in which its behaviour in actual conflagrations has been repeatedly noted. From such ordeals it has always emerged with high credit. Innumerable flat roofs, at home and abroad, have been executed in this material, and the reports concerning them all testify to their maintenance of efficiency in keeping out the wet, and their complete indifference to extreme variations in temperature. Seyssel asphalte (which is a bituminous limestone from the lower Jura, brought to a state of mastic) is perfectly inodorous and indestructible, never becoming brittle nor cracking. It has been used in a vast number of important buildings, including Windsor Castle, Buckingham Palace, Guy's Hospital, the Tower of London, Woolwich Barracks, Holloway Prison, etc.; and in the formation of flat roofs, has been of signal service in countries that are apt to be visited by hurricanes and heavy rainstorms.

New Clerk of Works at St. Paul's.

The Dean and Chapter of St. Paul's Cathedral have appointed Mr. W. E. Bolwell to be their clerk of the works in place of Mr. E. J. Harding, retired.

Messrs. Whiteley's New Premises.

In the account of Messrs. Whiteley's new premises at p. 199 of the Journal for February 21st, it should have been stated that the manufacturers and erectors of the staircase as illustrated on that page are Messrs. Walter Macfarlane and Co.

Shop in Castle Street, Edinburgh.

In the description of Mr. Hector Laing's shop in Castle Street, Edinburgh (Mr. W. J. Walker Todd, architect), illustrated by the centre plate and by a view on p. 208 of last week's issue, it should have been mentioned that the granite used so effectively in this work is "Glendougl Grey," supplied by the Douglas Granite Co., Ltd., Linksfield Road, Aberdeen.

In general design and construction simplicity was again the predominant feature. The aisles were merely passages for intercommunication, and where not vaulted were covered with simple lean-to roofs. There were no triforiums at first—for example, Fountains, Buildwas, and Kirkstall), although these were introduced later at Roche, etc. The details were kept simple in form; and while there are signs in later works of a break-away from former austerity, yet it is always marked by a quiet restraint and refinement. The treatment of gables and external walls was illustrated by examples at Fountains, Kirkstall, Byland, Tintern, and others.

Regarding pointed arch vaulting, it was shown that the Cistercians, though not the inventors, hastened the popularity of the former, and were among the first to arrive at the complete Gothic solutions of the ribbed vault, as the result of local experiment by the monks. The arrangement of conventual buildings and apartments was fully described. The lecturer appealed for a revival of arts and crafts, a revival of Gothic and styles practised by our fathers, founded on the principles of truth and virtue, as taught by the seer of Coniston, John Ruskin.—T. DAVIS.

GLASGOW INSTITUTE OF
ARCHITECTS.

At the quarterly general meeting of the Glasgow Institute of Architects, held last week, Mr. John B. Wilson, F.R.I.B.A., president, in the chair, it was reported that a letter had been forwarded to the Glasgow Corporation supporting the proposal that a town-planning exhibition be held in Glasgow, and a reply had been received that a sub-committee of the Corporation was at present considering as to having the exhibition brought to Glasgow at an early date. The Council had under consideration the proposal that the extension of the municipal buildings should be carried out by the city engineers' department, and a letter had been forwarded to the Corporation protesting against that proposal. The Council noted with satisfaction that the Corporation had remitted the matter back to the Committee for reconsideration.

The Council, recognising the importance of the National Housing and Town Planning Council to be held in Glasgow on March 19th and 20th, had appointed its members as delegates from the Institute to attend the conference.

A full report was made to the meeting regarding the steps taken by the Council for amendment of the conditions of the Finnart School competition. The meeting approved of the action of the Council in prohibiting members of the Institute from taking part in the competition in view of the unsatisfactory result of the negotiations with the Board. It was pointed out that the R.I.B.A. and the Edinburgh Architectural Association had also placed an embargo on the competition.

There was submitted to the meeting a resolution passed by the Council in terms of the articles recently adopted by the Institute, for the better regulation of competition, by debarring its members from engaging in competitions the conditions of which are considered unsatisfactory. The resolution, which was approved by the meeting, defined what is to be regarded as professional misconduct on the part of any member

White, Lic.R.I.B.A.; hon. librarian, Mr. E. R. Tate, Lic.R.I.B.A.; hon. secretary, Mr. Harold E. Henderson, Lic.R.I.B.A.; assistant hon. sec., Mr. J. M. Andrew; member of council, Messrs. A. E. Munby, A.R.I.B.A., S. R. Kirby, Lic.R.I.B.A., F. Dyer, K. Ward, Lic.R.I.B.A., and J. M. Andrew.

The prizes for the best set of measured drawings have been awarded by the assessor, Mr. A. E. Munby, M.A., A.R.I.B.A., to—1st, Mr. C. Leconby, and 2nd equally divided between Mr. D. Morrell and Mr. C. W. C. Needham.—HAROLD E. HENDERSON, hon. sec., 3, First Avenue, Haworth, York.

MANCHESTER SOCIETY OF
ARCHITECTS.*Three Centuries of Scottish Architecture.*

At a meeting of the above-named society on February 14th, Mr. A. N. Paterson read a paper entitled "Scottish Architecture, Ecclesiastic and Domestic, XV. to XVII. Centuries." In tracing the history of the early development of Gothic art in Scotland, he showed how till the 15th century Scotland followed in the wake of the general traditions of building in England; that then, when England had passed to the Perpendicular period of flattened arches, fan vaulting, and perpendicular windows, Scotland, severed from English influence by the war, developed an architectural character of her own. This she maintained for the two following centuries, but it was to France rather than England that she turned for friendship and inspiration. The time for the building of churches had now passed away, and Mr. Paterson showed with some excellent slides the development of the country house from the peel tower and castle.

GLASGOW ROYAL TECHNICAL COL-
LEGE ARCHITECTURAL CRAFTS-
MEN'S SOCIETY.

At a meeting of this society on February 6th, Mr. Jas. A. Lauchlan lectured on "Cistercian Monasteries"—(1) Historical, (2) architectural, (3) a plea for national art tradition. After glancing at the history of Europe from the beginning of the Christian era, the lecturer described the Anglo-Romanesque school of architecture and the influence on it from the continent. Although there was no style of architecture peculiar to any of the monastic orders, independent of the country in which they settled, yet the uniformity in arrangement of plan and design in Cistercian work makes the uses of this order easily to be picked out from that of their contemporaries, and this peculiarity of Cistercian work was pointed out as one of the most important influences operating on the architecture of the 12th century. The keynote of Cistercian work was shown to be a logical simplicity of purpose, a rejection of all unnecessary features of ornament, which was a direct contrast to the work of their contemporaries. The development of their plan from the simple unadorned churches of their first years to the typical Cistercian plans of Kirkstall and Fontenay's followed, then, after the development of the presbytery from the simple unadorned examples of Buildwas and Kirkstall to the more or less complicated systems of Cîteaux, Pontigny, and Fountains, Roche, and Byland, was shown, and explained by the need for more chapels as the number of monks in orders increased.

SOME NORTH-COUNTRY SCHOOL COMPETITIONS.

In recent school competitions, the school architect has been met with the difficulty of having to work to some degree in the dark, the regulations issued by the Board of Education in London having become obsolete through their own recent requirements. In the regulations, one of the rules stipulates that the class-rooms must be grouped round the central hall. The Board of Education have found out from experience that this interferes considerably with the efficiency of the school teaching, owing to the noise being transmitted from one class-room to another.

The central hall also interferes with the

efficient ventilation of the class-room, and the Board recommend that in certain types of school the hall should be isolated so that the class-rooms do not open directly off the hall.

Wallsend School.

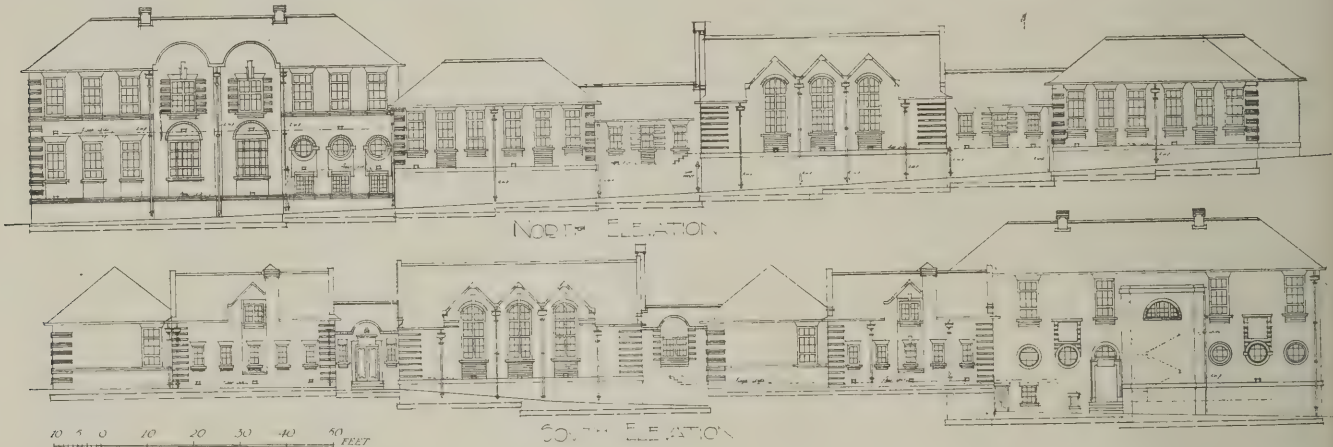

In the plans submitted for the Wallsend competition (here illustrated) the local Council required a detached room for the joint use of both the boys and girls. This competition was restricted to architects having an office within a radius of twenty miles. The school was to be designed in four departments, the infants' school providing accommodation for 400 scholars, and boys and girls' departments each 520. The housewifery department was to consist of laundry, cookery, and three

or four rooms, together with class-room. About twenty sets of designs were submitted, and Mr. A. W. S. Cross, M.A., F.R.I.B.A., the assessor, awarded the first premium to the design by Messrs. Marshall and Tweedy. The plans have since been approved by the Board of Education.

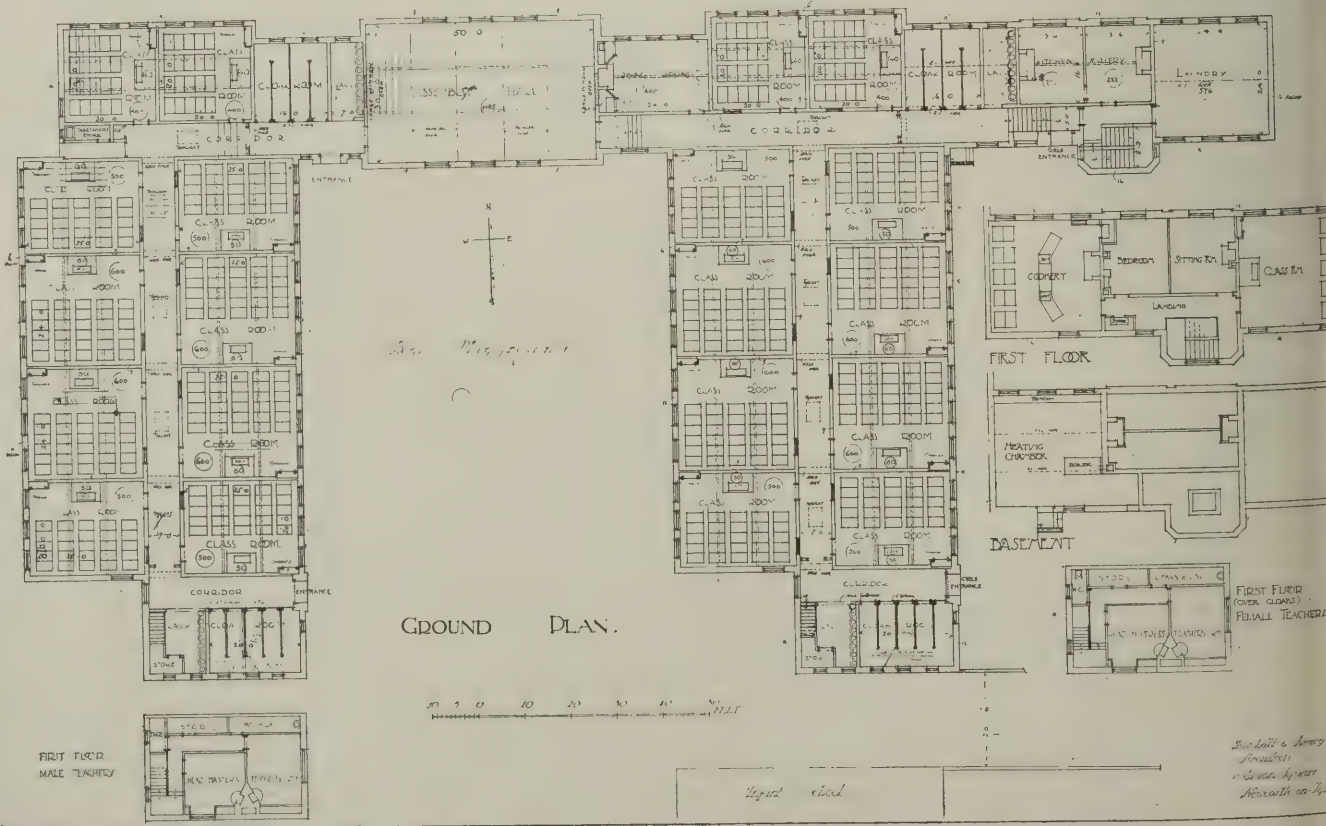

Walker Gate School.

Another competition recently held in Newcastle is that for a school at Walker Gate, to accommodate 730 children, and an infants' school for 400, for the Newcastle County Council Education Committee. The plans were assessed by Mr. Bilson, F.R.I.B.A., who awarded the first premium to Messrs. Marshall and Tweedy, Newcastle, the Education Committee confirming his report.

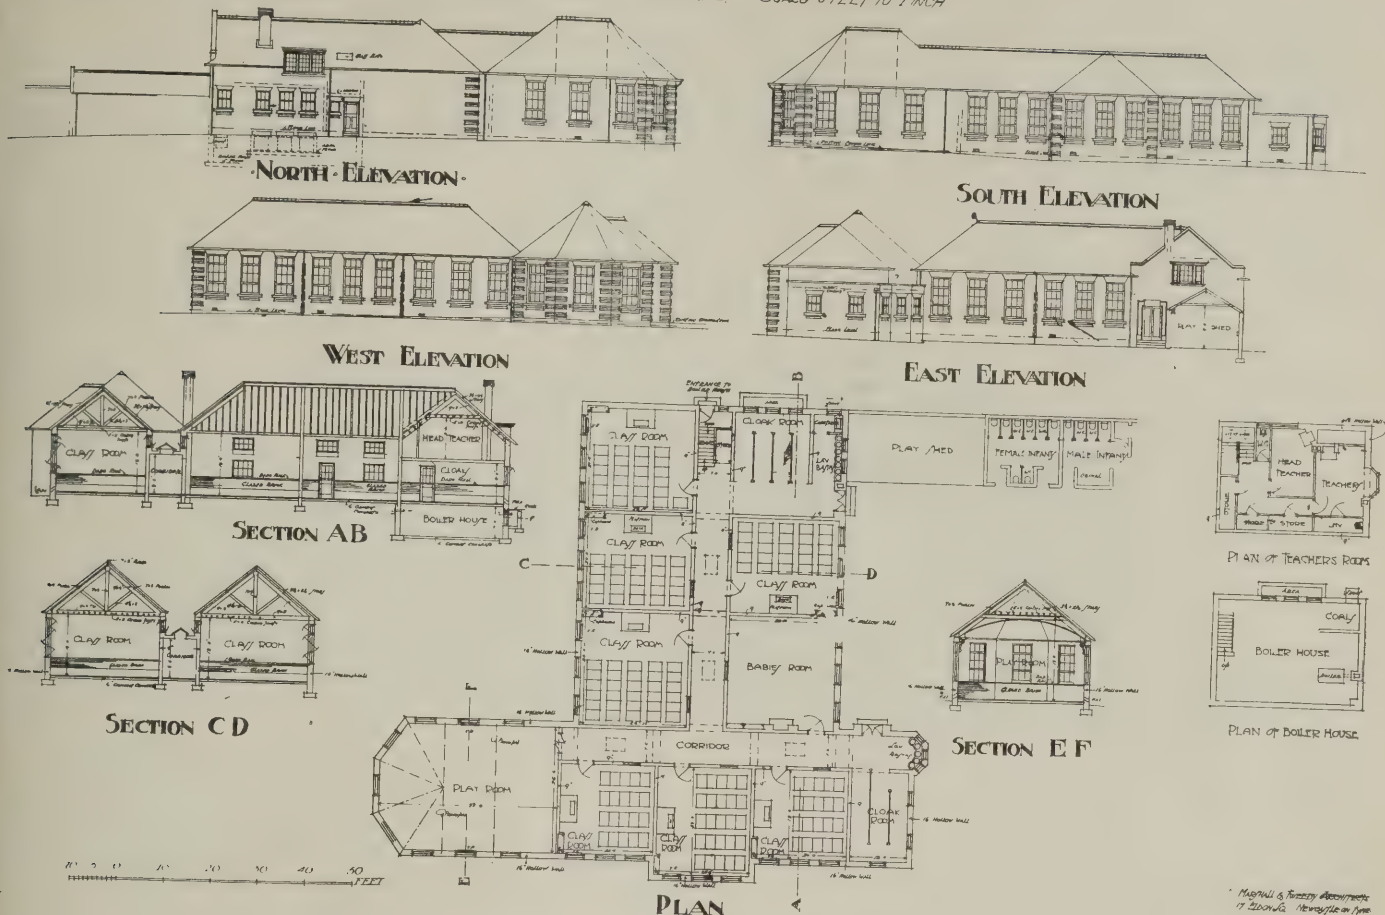

NEW COUNCIL SCHOOLS - WALLSEND FOR THE BOROUGH OF WALLSEND EDUCATION COMMITTEE

PROPOSED ELEMENTARY SCHOOL - WALLSEND: Girls & Boys Department.

NEW COUNCIL SCHOOLS WALLSEND INFANTS. SCALE 8 FEET TO 1 INCH

FIRST-PREMIERED DESIGN. MARSHALL AND TWEEDY, ARCHITECTS.

Whitley Bay School.

The plans for this school (p. 228) were awarded the first premium offered by the Northumberland County Council Education Committee for a new school to be erected at Whitley Bay, the assessor in this case being Mr. W. H. Knowles, F.R.I.B.A., F.S.A., who awarded the first place to Messrs. Marshall and Tweedy. The schools have since been erected from their designs, and were opened last year. This illustrates the type of school designed to meet the requirements of the Board of Education rules and regulations previous to the new recommendations.

Messrs. Marshall and Tweedy were also the successful competitors for the King Edward Schools, North Shields, recently erected for the Tynemouth Town Council, accommodating about 1,400 children.

SOME WORKING-CLASS DWELLINGS PROBLEMS.*

BY E. C. P. MONSON, F.R.I.B.A. F.S.I.

In introducing this subject the author proposed to deal principally with the problem of providing suitable housing accommodation for the poor worker or artisan, and such as would be provided under the Housing clauses of the Housing and Town Planning Act and other suchlike Acts.

"Housing" is a problem which has been a source of worry to all classes in all ages, and although vast improvements

have taken place it is still not now settled, and perhaps at the present time gives rise to more discussions, theories, and arguments than any other subject.

As the power of the Barons gradually became less, or as the power of the people began to assert and organise itself and the desire for more comfort and quietude arose, law and order as the natural consequence became established. So we come to the charming Tudor houses of the period when it may be assumed that houses for other than the lord first came to be erected. Previous to that the worker had either lived in the lowest storey of the lord's castle, and occupied the position of servant, or else had occupied a shanty erected under the shadow of the walls of the castle, and was a serf.

Hallam says that in the time of Edward the Third the cottages seem to have generally consisted of a single room without division or storeys. Chimneys were unknown in such dwellings till the early part of Elizabeth's reign, when a rapid and sensible improvement took place in the comforts as to housing of our yeomanry and cottagers.

After that we find the Jacobean and debased Gothic periods ending with the quaint Queen Anne residences, afterwards the Georgian types of dwellings, and finally the Victorian and present-day methods.

In the 18th and 19th centuries, great strides were made in building houses for the middle and poorer classes of the community, and in London itself many hundreds of streets were laid out and developed about that time. In fact, previous to then, London was more or less a small place to what it so soon

afterwards became, owing to all sorts of restraints—Acts of Parliament and the like—which had been attempted and passed to keep down house building. Many of these areas, however, which were so hurriedly covered with speculating-built houses soon came to grief and developed into slums, and, besides being insanitary, were badly designed, and numbers were either built on the old-fashioned back-to-back principle, or else provision was made for only a very small back yard, and only in the cases of the large and more important houses was there any more than a very limited air space provided, and anything was thought to do for the poor. These are now being or have had to be removed to make way for something else. Better houses, however, were built fronting around a square, which of course was what we consider more up to date.

Thanks to the munificence of such men as Mr. Peabody, Mr. Lewis, Mr. Guinness, Mr. Sutton, and many others who have lavishly given or left of their substance for the acquisition of sites and erection of dwellings for the poor, this matter is being dealt with. Then again there are Sir W. H. Lever of Port Sunlight, Mr. Cadbury of Bournville, and Mr. Rowntree of York, who have launched out and shown what personal sacrifice and a desire to better the conditions of everyday life can accomplish during their lifetime.

Then there are societies like the Letchworth Garden City, Harborne Tenants (Birmingham), Hampstead Garden Suburb, Ealing Tenants, and many others, where people can go to purchase the houses which are put up on a well-

FIRST-PREMIATED DESIGN FOR SCHOOLS AT WALKER GATE.

ordered co-operative principle and live together on co-operative lines.

Points with which the author dealt in some detail were as follows: (1) Which is it advisable to build—block dwellings, or (2) cottages?; (3) the block *versus* the cottage; (4) if cottages, whether detached, semi-detached or in rows; (5) number of houses to the acre; (6) the essentials of the best house built cheaply.

Block Dwellings are divided into two kinds—(a) The Associated.—A type which is quite out of date. They comprise living room and one or two bedrooms only, and all scullery and sanitary arrangements are apart from the living-rooms and used by the tenants of more than one, very often three or four other tenements. (b) *The Self-contained.*—This type is good, each flat having everything which an ordinary cottage would have, and combining all the comforts of a house without interference from anyone.

The cost of block dwellings, according to Alderman Thompson, altogether apart from the cost of the land, averages about £100 per room, and the land costs about £75 per room, making the total about £175 per room. This is higher than the cost of the cottage per room, but it can be readily seen that where the site is in London, or other large cities, it is impossible or impracticable even from a philanthropic standpoint to build other than block dwellings. Block dwellings, however, should not be built higher than five storeys, and only four if the cost of the land is such as will allow this, owing to the vital question of adequately lighting all the rooms.

In the case of the trustees of the will of the late W. R. Sutton, the site at the corner of Old Street and City Road, London, E.C., comprised only 1½ acres, and cost about £95,000, and the buildings just over £70,000, a total of £165,000 for 284 tenements and 14 shops—885 rooms

and sculleries and shops, etc., which works out at about £80 per room for the buildings and about £107 per room for the land; and on another site where buildings are now being erected at Chelsea, the cost of the land was £76,000 for about 3½ acres, and the building contract is £176,000, a total of £252,000 for 675 tenements and 34 shops—2,175 rooms and sculleries and shops, etc., which works out at about £80 per room for the buildings and about £35 per room for the land, and in both these schemes after deducting 40 per cent. for repairs, rates and taxes, and other outgoings, the rents are so arranged as to produce 2½ per cent. only on the total capital outlay.

The blocks here provide for one, two, three, or four roomed tenements, and in all these tenements accommodation is made for a scullery-bathroom, separate w.c., larder, coal cellar, etc., which is not counted when speaking of the number of rooms. The entrances to the flats are all from staircases. Every floor is of fire-resisting materials, as also are the staircases and roofs; the playgrounds and roadways are made with tar macadam; shrubberies are planted wherever possible, and care is taken to tend the trees and shrubs so that they shall have a fair chance of life. Staircase walls are in glazed bricks, and generally the whole of the work is carried out not so much with the idea of building cheaply as that of saving in the cost of upkeep and renewals.

In Liverpool, where the Corporation have been doing a great and praiseworthy work on the Bevington Street area, and where they are proposing to spend a further considerable amount of money, the block dwellings are to comprise living-room, one or two bedrooms, scullery, w.c., but no bath. The entrances to tenements are from balconies placed outside the buildings, but the author was not greatly in favour of this particular

method of entrance. It saves space, however, because one staircase can be made to serve a larger number of tenements than if the entrances were direct from the staircase.

In Manchester very many dwellings of this latter character have been put up by the Corporation, and it is becoming quite a usual thing for large municipalities to go into the question of doing (as rightly they should do) something for the poor.

Cottages.

The Sutton Trustees are purchasing a site at Birmingham, about 21½ acres in extent, at a cost of about £18,500 including roads and sewers, and the proposition is to build 215 houses and cottages of varying sizes, accommodating a total of 251 families in 1,000 rooms and sculleries, the whole scheme working out, with roads and sewers, at about £60,500, which gives an average cost per room of £40 for the buildings and £18 for the land and roads. The figures from the author's own work prove conclusively that the cost per room in the cottage for buildings and site is less than the cost per room and site in the block. The cost of cottage building as given in "Housing Up-to-Date," by Alderman Thompson, averages roughly from £40 to £70 per room, and the average site cost about £7 10s. per room, but it is impossible to make any comparison, because cottages can only be built to be productive where the cost of the ground is comparatively low.

The Block versus the Cottage.

The great question with regard to block dwellings is whether they are more or less healthy than the cottages, and it must be admitted that good health is dependent not on one condition but on many. The primary command of creation was "Let there be light," and it

because the builders of block dwellings in some countries have neglected to obey this command that the block dwellings exercise such a mischievous influence in regard to the health of the people.

Another point against block dwellings is that they are liable to be overcrowded; this, however, ought never to happen where the superintendent and his assistants keep a sharp look-out.

I agree with Mr. Henry Aldridge, the energetic Secretary of the National Housing Council, in his definition of what every workman's home should be. "To begin with, every normal, healthy dwelling for a family should possess at least three bedrooms—one bedroom for the parents and two bedrooms to enable the children to be separated in the years of youth and adolescence. The delicacy and privacy of individual life in the years of youth form one of the most important conditions for physical improvement."

The standard of a normal, healthy home for a workman's family comprises three bedrooms, large living-room, scullery and bath—and wherever possible a parlour; and no workman's home can be regarded as properly equipped unless it has a garden, however small. On the broad question, taking all things into consideration in connection with this clause, the cottage comes out best and wins the case, and should be built wherever possible.

Whether the cottage should be detached, semi-detached, or in rows depends very largely upon the number it is desired to place upon any given plot of land, and makes a considerable difference in the number to be so placed, because if they are in rows more land is available for building—and the overcrowding of houses is to be deprecated—but even if they are so placed it is far better in my opinion to provide a small yard, then the back way, and beyond that the garden, and, to, say, every four or six houses, run a passage-way from back to front, with rooms over, to connect up the back way as much and as often as possible, and prevent its becoming the nuisance it sometimes does; but if the number of houses to be erected to the acre is generally speaking, says Mr. Raymond Unwin, reduced to anything like 15, terrace houses with back passages will be found to be a more expensive method of development than with passages between the houses.

Is it better, however, to build houses semi-detached? Here again the question of money comes in, for it is impossible to build in this manner as cheaply as terrace houses; there are three main walls to be erected to start with, instead of two. The objectionable features, however, which may arise in connection with the back way in the terrace house are one away with, and every house has its garden directly attached thereto. Detached houses are much better, but again the cost is still more. The best way of arranging houses economically is semi-detached, but the passage between the houses should be not less than 4 ft. wide, and can be used jointly by the occupiers on either side; this method does away with the obnoxious back passage, and is the best solution of that very irritating law regarding back ways which at the time every local authority sought and fought for until they found out the cost of up-keep, lighting, etc., and would now glad to be rid of.

Number of Houses to the Acre.

At present in certain districts as many as 35 and even more houses are built,

on an average, upon every acre of ground. This of course means overcrowding and discomfort, terrace houses and practically no gardens, but 13 to the acre is a very usual number, and is good. The Birmingham Corporation in their Town Planning Scheme for East Birmingham have fixed the limit at 10 per gross acre, with a density rate of 20 per gross acre. This has caused dissatisfaction, and the builders and landowners are grumbling. A good all-round average is 13 to 14 per gross acre, giving plenty of garden ground.

With 25 houses to the acre, the tenant pays 7½d. per week for 127 yds. With 9.6 houses to the acre, if the tenant paid 1s. 0½d. per week he could have 423 yds. for his plot, and the landlord would make the same profit upon his land, because while the effect of reducing the number of houses to the acre from 25 to 9.6 is to increase the cost per plot by 68 per cent.; its effect also is to increase the area of the plot by 333 per cent.

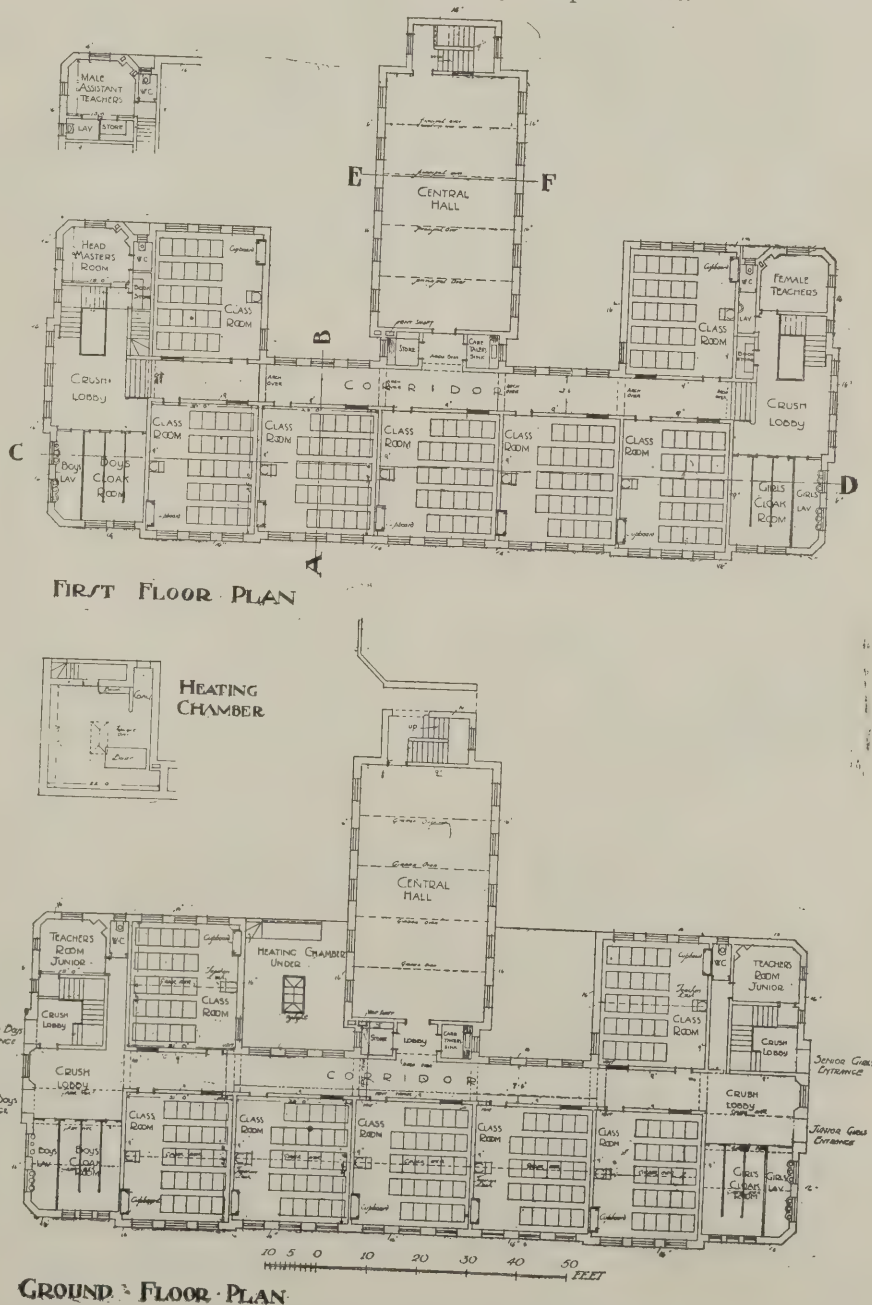

How to Build Houses Cheaply.

Under the Housing and Town Planning Act and the various Small Holders'

and other Acts great incentive will be given to people to build houses for themselves, either through some of the approved societies or by borrowing the money in other ways with the aid of the Acts. I do not propose to go into the many methods in which this can be done, but will only say that I consider the best way to build cheaply is for the client to employ a thoroughly practical and responsible architect, not a faddist or creamer after the impossible, but one who understands his subject and can give the best results for the least money.

DISCUSSION.

Mr. H. Freyberg, F.S.I. (London), in proposing a vote of thanks, said that the difficulty in London was that as fast as slum areas were cleared away they blossomed out in all their fruitfulness in other parts of London. It was absolutely useless for individual effort to go on unaided, and it was of no great practical value for any municipal body to clear away slum areas in their own particular municipality if they were allowed to grow up in others.

FIRST-PREMIATED DESIGN FOR SCHOOL AT WALKER GATE, NEWCASTLE-ON-TYNE.
MARSHALL AND TWEEDY, ARCHITECTS.

Mr. G. A. T. Middleton, A.R.I.B.A., seconded, remarking on the statement that in early days houses were grouped close round the castle walls, and said that, in England at all events, they had their little village communities right through the twelfth, thirteenth, and fourteenth centuries very much as they were at the present day; each man living in his own cottage—king of his own castle—a style of living which was considered the best for the workmen of to-day.

Mr. Henry R. Aldridge (Secretary of the National Housing and Town Planning Council), supporting the vote of thanks, said that Mr. Monson was doing what was absolutely essential at the present time in trying to work out from the architect's point of view some of the very difficult housing problems. Mr. Monson had done very practical work in designing the better type of workman's cottage, and he (the speaker) very much appreciated his services in this direction. It was quite

possible, he thought, to get Mr. Monson's ideas brought in with due economy, and unless economy went hand in hand with development, they would never get town planning to help the people it was intended to help. The "grandiose" type of Germany was admirable from their point of view in their desire to make them notable towns, but in England town planning would have to be dealt with on different lines, taking the home as its starting point instead of the "boulevard," as in Germany.

Mr. Noel D. Sheffield said that the class of men and women who might be called casual labourers seemed quite beyond any scheme for promoting their welfare. In many cases it was the occupier who made the slum, and even if persons of that type were shifted to a popular district amid healthy surroundings they would very soon convert the whole neighbourhood into a slum area.

Joint passages between the houses were economical, as they saved frontage without any apparent diminution of the front garden. He considered housing schemes must be to a large extent philanthropic, as few business or commercial men would spend large sums of money for a mere 2½ per cent. return.

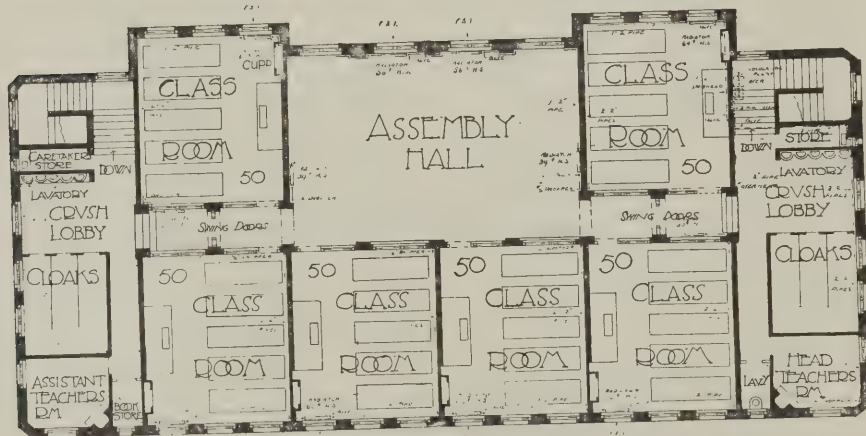

Mr. Charles F. Mitchell said he was glad that it was in the cottage rather than the block dwellings system that the solution of the housing problem lay, because in giving a man a house of his own with plenty of garden space and a common ground for the children they were giving him the joy of life.

Mr. F. Endell Rosser agreed with the lecturer in his advocacy of the parlour which he thought gave to the working man and woman a certain amount of self-respect. Wherever possible, he always put in a parlour. He saw no objection to a *cul-de-sac* under the conditions suggested, and thought a nice effect could be obtained by running the front garden through at the two end houses and placing a house at the other end facing down the *cul-de-sac*. A great saving in road charges would thereby be effected.

Alderman W. Thompson (Chairman of the National Housing and Town Planning Council) said that architects had only recently, comparatively speaking, turned their attention to the cheap house. He had never paid them to give the matter serious thought; the design of a cottage and the superintendence of its erection required as much care and trouble as larger work, and when it was completed the result of their efforts was often "lifted" by builders and others almost to the brick, without any kind of fee. If architects could devise some reasonable means, without putting any undue oppression upon the production of houses, which would protect a man who had given his life to the consideration of the subject, they would be justified in asking Parliament to accede to their demands. The present Act was not strong enough to get at the trouble. So far every house erected on their estate had been designed by a proper architect; every house would have to be examined by an architect, and they would insist upon having a competent man for every house put up. The average number of houses there to the acre was not more than six. The maximum number was twelve to the acre, and the opinion throughout the country seemed to be hardening on the question. The zoning system of streets radiating from a centre would have to be adopted where land was purchased which already had houses standing upon it. There could not be a slum anywhere within ten square miles of their estate, their neighbours benefiting by their scheme. On an estate 200 acres in extent, twenty acres were given up to open spaces.

Mr. Ewart G. Culpin (Secretary of the Garden Cities Association) said that it was a glad sign for housing reformers that architects were taking up the subject. They had all suffered so much from the deadly monotony of streets of houses erected from builders' plans, the cost of building and establishment charges being out of all proportion to the result obtained. He gave instances supporting his contention that without doubt it was evident that the cottage condition was going to be the salvation of the world.

Mr. Percy B. Tubbs, F.R.I.B., having made a few remarks, the motion was put and carried, and Mr. Monson replied.

First-Floor Plan.

Ground-Floor Plan.

FIRST-PREMIATED DESIGN FOR ELEMENTARY SCHOOL, WHITLEY BAY.
MARSHALL AND TWEEDY, ARCHITECTS.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

The L.C.C. Draft Regulations. In our issues for December 6th, 13th, and 27th, 1911, we published the proposed regulations with respect to the construction of buildings wholly or partly of reinforced concrete, as drafted by the Building Acts Committee of the London County Council. The chief object in publishing the draft must have been to elicit criticism, and no doubt this has been abundant enough. Probably much of it has been "forwarded to the proper quarter," and some of it has been published. "An Engineering Correspondent" of the "Times," for instance, has reviewed the draft with much acuteness, pointing out several particulars in which it seems to be in need of amendment. He admits that Part I. (see page 604 of our issue of December 6th) is a clearly expressed definition of what is meant by a reinforced concrete building, but he thinks that Clause 5 should be so modified as to enable the designer to combine steel framing and reinforced concrete in one building if he so desires. Whether or not he is correct in assuming that a strict reading of this clause would prevent that combination will, we think, be pretty clearly seen on a re-perusal of the clause, which is as follows: "5.—Nothing in these regulations shall be deemed to authorise the construction of buildings of reinforced concrete in which the loads and stresses are not transmitted through each storey to the foundations by a skeleton framework of reinforced concrete or partly by a skeleton framework of reinforced concrete and partly by a party wall or party walls." There is no mention of steel framing. Is the omission accidental, or intentional? A very slight modification of the clause would set the matter right.

Steel-frame Construction. But it is difficult to believe that the omission was accidental, seeing that the committee, when drafting the clause, probably had before them Clause 22 of the 1909 Act. Why did they not follow the wording of that Act more closely, accepting the gist of this passage?—"transmitted through each storey to the foundations by a skeleton framework of metal or partly by a skeleton framework of metal and partly by a party wall," etc. Unless the draft regulation is amended so as to include steel-frame construction by express provision, trouble is sure to arise, because the administration of the Act is sure to be strictly in accordance with its letter; and even though it may be possible to obtain occasional exemptions from the Council, that process is troublesome and apt to cause unnecessary anxiety and delay. The combination of reinforced concrete and steel-frame construction may, through some happy intention or other contingency, become much more desirable; and yet here is a use of the draft that seems tacitly to prohibit it—for what reason, if any, is difficult to conjecture.

Wind-pressure. The clauses relating to wind-pressure are of such a character as to inspire regret that the authors of such documents cannot be

asked to expound their reasons. Clause 20 of the 1909 Act provides that: "All buildings shall be so designed as to resist safely a wind-pressure in any horizontal direction of not less than thirty pounds per square foot of the upper two-thirds of the surface of such buildings exposed to wind-pressure. In the new draft regulations, the clauses relating to wind pressure are as follows: "18a.—All buildings shall be so designed as to resist safely a wind pressure in any horizontal direction of not less than twenty pounds per square foot of the whole projected surface normal to the direction of the wind. 18b.—All structures or attachments whatsoever in connection with a building, including towers or other parts which extend above the flat roof or gutter adjoining thereto, shall be so designed as to resist safely a wind pressure in any horizontal direction of not less than forty pounds per square foot of the whole projected surface normal to the direction of the wind." Clause 107 of the draft provides that: "Each panel in any external wall shall be designed to resist safely a horizontal pressure of at least thirty pounds per square foot assumed to be acting uniformly over the area of one panel from either side." Is all this complication necessary? It is surely confusing to remember that, while in the 1909 Act there is a generalisation on 30 lbs., in the draft one gets 20 lbs. as a generalisation, with 40 lbs. and 30 lbs. for particular circumstances, and it ought to be possible to simplify the rule. One would like to know upon what meteorological data the calculations for wind-pressure are currently based. Those given in the text-books on building seem to be somewhat ancient, and it may be doubted whether the accepted figures for wind-pressure—storm, 12½ lbs. per square foot; violent storm, 18 lbs.; hurricane, 32 lbs.; violent hurricane, 50 lbs.; gust in 1866, 80 lbs.—are not in need of revision. Also, there is wisdom in the commonplace that while in most situations a pressure of 40 lb. per foot super. of the surface exposed to its action may be assumed as the maximum, yet in exposed situations a higher value, of 50, 56, or even 60 should be allowed. It is a matter that is ripe for close scrutiny.

Superfluous Formulae.

The critic under notice deprecates as being superfluous the introduction of formulae into the draft, and with regard to the following: "Bending moment at the fixed end of a cantilever with the load uniformly distributed = $Wl^2/2$," he grows sarcastic: "It seems odd that a regulation of the London County Council should be needed to confirm a law of Nature; although it may be admitted that if complex formulae are to become regulations it would be only logical to lead up from the one quoted above; perhaps we ought to begin with 'twice two is four.'" There is justness also in the remark provoked by the minute directions as to maximum distance between bars, thickness of covering concrete, jointing of bars, fishtailing of ends, grip length, shear reinforcement, etc.—i.e., that the description might with advantage be considerably condensed: "What is required is regulations, and not

specifications." Other points noted are that the tables of working stresses show, in some cases, higher figures than those in the R.I.B.A. rules, and might lead to the district surveyor's insisting on testing-loads that would crack the concrete; that the compressive working stresses seem to involve too small a factor of safety; and that the test loads in some instances tend to run to extremes. It will be interesting and perhaps instructive to compare the L.C.C. draft with the regulations that have just come into force in New York city, and, accordingly, the latter are printed in another part of the present issue.

The Aesthetic Side.

Our remark, in last month's Concrete and Steel Section, that the long interval between the reading of the paper by Professor Berestord Pite on "The Aesthetic Treatment of Concrete" in June last, and the resumption of the discussion upon it on February 8th, might render its details, if not its main argument, a somewhat dim memory, has been confirmed by the event. On the resumption, Professor Pite very obligingly read his paper again, and showed a series of lantern slides of reinforced concrete buildings. It must be confessed that the discussion left the problem pretty much where it was. Most of the speakers seeking refuge in the rather vague generalities which beset such subjects. One speaker thought that concrete need not be treated with coarseness, but should be treated with the highest degree of refinement. Another, that in architecture the effect of beauty ought to be attained; and so forth. Mr. Arthur T. Bolton, F.R.I.B.A., recalled the remark of Garbett, written at about the time of the Gothic revival, that "In Greece we have the architecture of the post and lintel, and in Rome we have the architecture of the arch, and there is no other constructive principle except that of the truss." Garbett could not have foreseen the significance that the truss was destined to assume in the development of reinforced concrete construction. Mr. Bolton seemed to suppose that the ceiling of the cold-water bath of Caracalla at Rome, where great quantities of T-irons had been found, might have been constructed on some system akin to reinforced concrete; while the roof of the Pantheon had some extraordinary truss construction of flat bars of bronze: which was all very interesting, but did not very plangently hit the chief point under discussion. Mr. E. P. Wells was more direct. He did not see why the usual methods of moulding and treatment should not apply to reinforced concrete, which, he seemed to complain, was somewhat unfairly condemned as an artificial material, whilst in fact it was no more artificial than brick, against which no similar prejudice is ever expressed. The one definite suggestion of the discussion came from a gentleman who thought that the early Greek example of the Colossus, where a great wall of burnt brick was plastered over, and large figures were moulded in the plaster, might possibly offer a hint for the decorative treatment of reinforced concrete. On the whole, the discussion was disappointing.

RECREATION HALL, SOUTHALL. A. G. R. MACKENZIE, A.R.I.B.A., ARCHITECT.

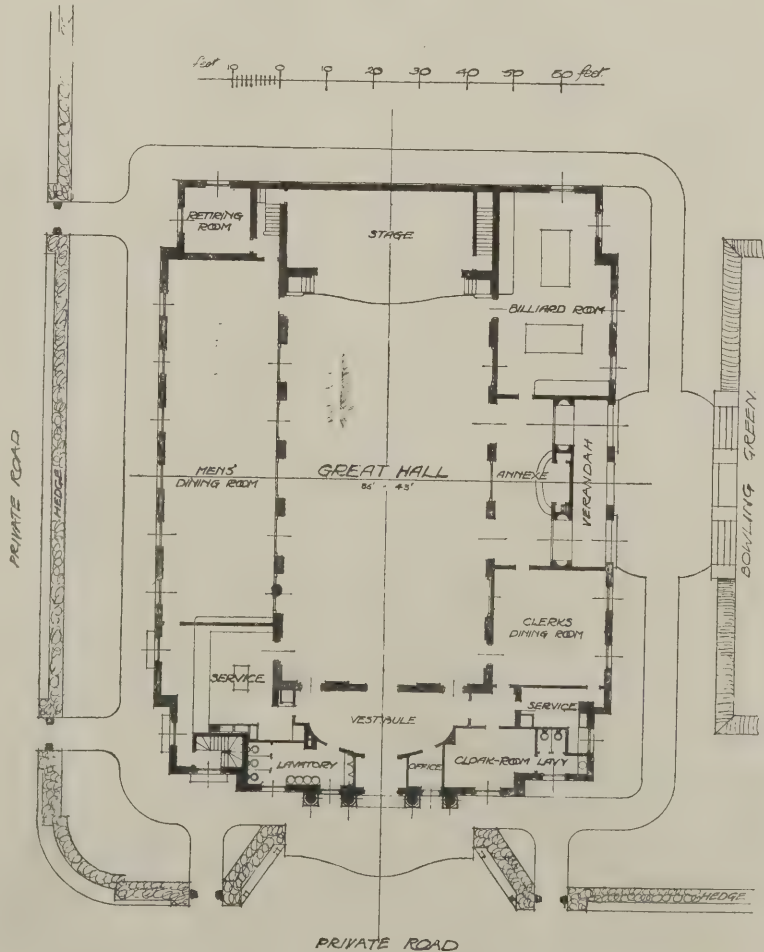

RECREATION HALL, SOUTHALL A. G. R. MACKENZIE, A.R.I.B.A. ARCHITECT

NEW RECREATION HALL, SOUTHALL.

This building was designed by Mr. A. G. R. Mackenzie, A.R.I.B.A. (of A. Marshall Mackenzie and Son, 1, Victoria Street, Westminster), for Messrs. Otto Monsted, Ltd., margarine manufacturers, as a recreation hall for their employees. The exterior is designed in a Danish style of architecture, contemporary with that of Louis XVI., in France. The building contains a large hall, 86 ft. by 43 ft., laid for roller skating, and having a stage at one end. Grouped around are a men's dining-room, billiard-room, clerks' dining-room, services, cloak-rooms, etc., the kitchens and caretaker's apartments being on the first floor. The building is of brick covered with cement plaster, the dressings to the windows and doors being of Dumfries stone. The roofs are covered with black Dutch pantiles, supplied by Messrs. Roberts, Adlard and Co., of 26, Bermondsey Wall, S.E. The two small reinforced-concrete chimneys which are just visible in the exterior illustrations, and of which a detailed drawing is also reproduced, were erected by the Indented Bar and Concrete Engineering Co., Ltd., of Queen Anne's Chambers, Westminster. An interesting point in connection with their design is that the flat concrete slab from which the chimney springs is used as a base to afford stability to the reinforced concrete chimney against overturning. The roof to the recreation hall, also of reinforced concrete, is intended for use as a stand for spectators. Of this a plan and sections are given on page 232. The builders were Messrs. A. and B. Hanson, of Southall.

proofing compounds a high degree of impermeability, it is stated, may be obtained, and in the cities of Cologne and Stettin, which require an absolute impermeability under a pressure of about 9 lb. per square inch, or an equivalent head of about 20 ft., concrete pipes are said to give entire satisfaction. In the observed cases of leakage or fracture of these pipes, it was found that failure resulted either from improper plugging

of the joints or from such contributing conditions as would have caused a similar failure in cast iron or clay pipes. The author states that special care is necessary in the selection of the materials used in the manufacture of these pipes, particularly in the choice of the sand. As a result of tests conducted by the Corps des Ponts et Chaussées, the author believes that any high-grade Portland or slag cement may be used. The latter

RECREATION HALL, SOUTHALL: GROUND-FLOOR PLAN.

CONCRETE WATER MAINS.

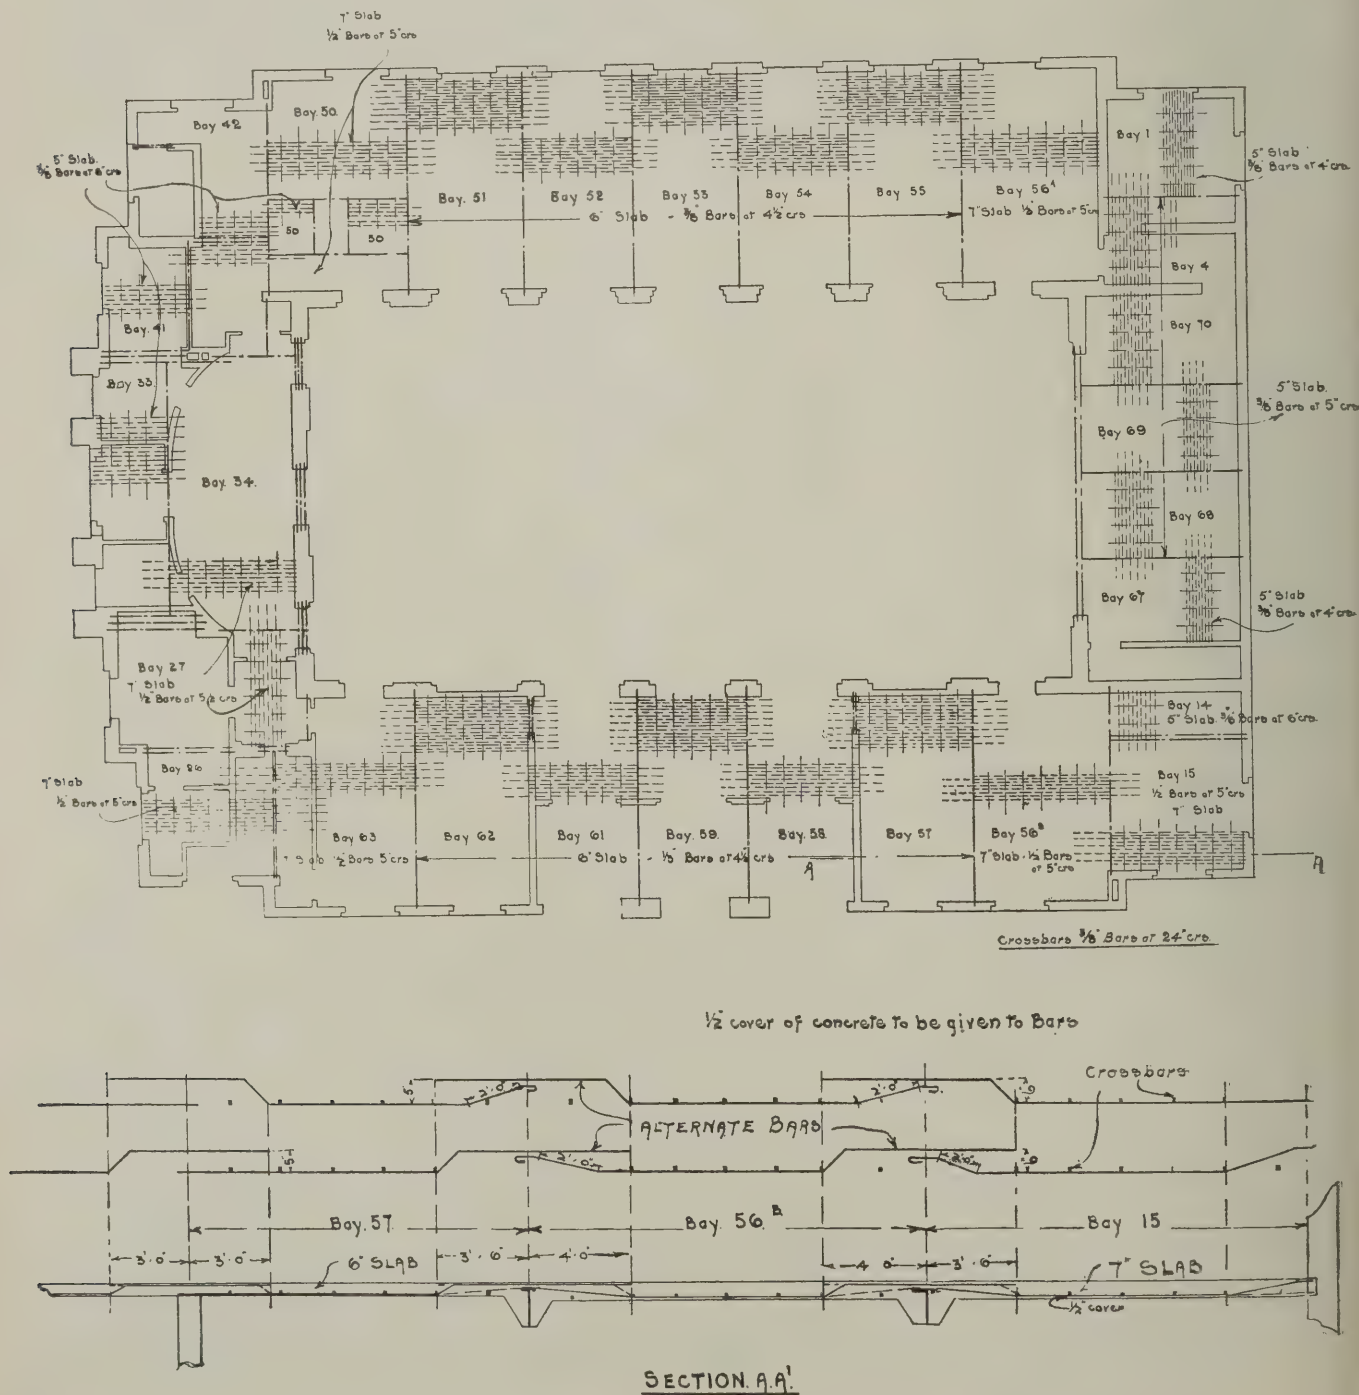

The use of water pipes made of concrete for municipal water supplies is discussed by M. E. Bazin in a recent issue of "Nouvelles Annales de la Construction." He notes their adaptability for carrying waters either neutral or low in acid or alkali, and under low pressures. Such pipes do not affect the taste of the water passing through them, and, it is stated, afford little if any opportunity for the development of vegetable organisms on the inside surface. By the use of water-

is said to be of special value on account of its behaviour under water or in wet ground. Under such conditions it is said to acquire a strength greater than that of Portland in a short period of time. The chemical and mineralogical composition of the sand should be investigated before a selection is made. Sand that is friable or contains soluble substances such as gypsum or salts of magnesium is not suitable. For these reasons argillaceous and calcareous sands are to be avoided, thus practically limiting the choice to siliceous sands. Of these, river sand is preferable to sea sand. If the latter is selected, it should be thoroughly washed before using it in the concrete. The author emphasises the necessity of using the same precautions in the selection of the gravel, and suggests the need of a careful study of proportions to secure uniformity.

REINFORCED CONCRETE POLES.

It is confidently asserted that wooden telegraph poles will soon be a thing of the past in New Zealand, and that in the future they will give place to the more durable poles made of reinforced concrete. These poles, being uniform in design, will present a more pleasing appearance to the eyes than do the wooden poles, which are rough-looking and decidedly disfiguring to the streets in which they are placed. The department found that the concrete poles are superior to wood or iron poles in every respect. For more than a year, experiments have been carried on for the department, with the object of making a concrete pole that would be much lighter than those made from the ordinary reinforced concrete. The experiments have been most successful. By

a chemical process poles can now be manufactured which are very little heavier than totara wood. Tests recently made with an 18 ft. pole showed that it could carry a greater weight than either wood or iron. Although the hollow in the reinforced-concrete poles materially reduced the weight, they were not nearly so light as the poles made with the new material. The average life of a wooden or iron pole is set down at about nine years, while it is considered that the reinforced-concrete poles and those chemically treated are practically everlasting. It is now the intention of the Post and Telegraph Department to have pillar boxes constructed of reinforced concrete chemically mixed, instead of the iron boxes now in use. Tests show that these boxes are stronger and lighter than iron, while the cost is said to be only half.

RECREATION HALL, SOUTHALL. ROOF-FLOOR PLAN, AND SECTION SHOWING REINFORCEMENT.

NEW YORK'S NEW REGULATIONS FOR REINFORCED CONCRETE CONSTRUCTION.

As noted in another part of the present issue, it will be interesting, at the moment when the London County Council is formulating new rules for the regulation of reinforced concrete construction, to compare these with those that have been adopted by the Superintendents of Buildings in the five boroughs of the City of New York, and that came into operation at the beginning of the present year:—

1. The term reinforced concrete in these regulations shall be understood to mean an approved concrete mixture reinforced by steel of any shape.

2. Reinforced concrete will be approved for all types of construction if the design is in accordance with good engineering practice and stresses are figured as required by these regulations.

3. Before permission to erect any reinforced concrete structure is granted, complete drawings and specifications must be filed with the superintendent of buildings, showing all details of the construction, the size and position of steel reinforcement, and the composition of the concrete.

4. The concrete for reinforced concrete structures shall consist of a wet mixture of 1 part of cement to not more than 6 parts of aggregate, fine and coarse, either in the proportion of 1 part of cement, 2 parts of sand, and 4 parts of stone or gravel, or in such proportion that the resistance of the concrete to crushing shall not be less than 2,400 lb. per sq. in. after hardening for 28 days.

5. Only Portland cement meeting the standard specifications for cement of the American Society for Testing Materials shall be used in reinforced concrete structures.

6. Fine aggregates shall consist of sand, crushed stone or gravel screenings, passing when dry a screen having $\frac{1}{4}$ -in. diameter holes, and not more than 6 per cent. passing a sieve having 100 meshes per lineal inch. It shall be clean and free from vegetable loam or other deleterious matter.

7. Mortars composed of 1 part Portland cement and 3 parts fine aggregate by weight when made into briquettes should show a tensile strength of at least 240 lb. per sq. in. at 28 days.

8. Coarser aggregate shall consist of crushed stone or gravel which is retained on a screen having $\frac{1}{4}$ -in. diameter holes and graded in size from small to large particles. The maximum size shall be such that all the aggregate will pass through a 1-in. diameter ring. The particles shall be clean, hard, durable, and free from all deleterious material.

9. Steel for reinforcement of concrete shall meet the requirements of the standard specifications for steel reinforcement of the American Railway Engineering Association.

10. Wire used for column hoops shall be drawn from open hearth billets and shall have an ultimate tensile strength of not less than 85,000 lb. per sq. in.

11. The span length for beams and slabs shall be taken as the distance from centre to centre of supports, but need not be taken to exceed the clear span plus the depth of beam or slab. Brackets shall not be considered as reducing the clear span.

12. Length of columns shall be taken as the maximum unsupported length.

13. All reinforcement shall be accurately located and secured against displacement.

REINFORCED CONCRETE CHIMNEY AT RECREATION HALL, SOUTHALL.

ment. The reinforcement for slabs shall not be spaced further apart than two and one-half times the thickness of the slab.

14. Slabs shall not be less than 4 in. in thickness for floors and $3\frac{1}{2}$ in. for roofs.

15. As a basis for calculations for the strength of girders, beams, and slabs the following assumptions shall be made.

(a) A plane section before bending remains a plane after bending.

(b) The modulus of elasticity of con-

crete in compression remains constant within limits of working stresses fixed in these regulations.

(c) The adhesion between concrete and reinforcement is perfect.

(d) The ratio of the modulus of elasticity of steel to the modulus of elasticity of concrete is 15.

(e) Concrete has no value in resistance to tension.

(f) Initial stress in the reinforcement due to contraction or expansion in the concrete is negligible.

16. The bending moment of slabs uniformly loaded and simply supported shall be taken as $Wl/8$, where W =total load and l =span.

17. The bending moments at the centre and at intermediate supports of floor slabs continuous over two or more supports shall be taken as $Wl/12$.

18. The bending moments of slabs that are reinforced in both directions and supported on four sides and fully reinforced over the supports (the reinforcement passing into the adjoining slabs) may be taken as Wl/F for loads in each direction, in which $F=S$ when the slab under consideration is not continuous or when continuous over one support, and $F=12$ at both centre and supports when the slab is continuous over both supports. The distribution of the loads shall be determined by the formula

$$r=l^4/(l^4+b^4)$$

in which r equals proportion of load carried by the transverse reinforcement, l equals length, and b equals breadth of slab.

19. Simply supported beams shall be considered as simple beams with bending moments of $Wl/8$.

20. Beams supported at one end and continuous at the other shall be considered as partially restrained with a bending moment of $Wl/10$ at the centre and $Wl/8$ over intermediate support.

21. Beams supporting rectangular slabs reinforced in both directions shall be assumed to take the proportions of load as determined by the formula in section 18.

22. The bending moments at centre and support for beams or girders continuous over two or more supports shall be taken at $Wl/12$.

23. The bending moments due to other than uniformly distributed loads shall be computed according to accepted theory.

24. Where adequate bond between slab and web of beam is provided, the slab may be considered as an integral part of the beam provided its effective width shall not exceed on either side of the beam one-sixth of the span length of the beam nor be greater than six times the thickness of the slab on either side of the beam, the measurements being taken from edge of web.

25. Members of web reinforcement shall be so designed as to adequately take up all involved stresses throughout their entire length. They shall not be spaced to exceed three-fourths of the depth of the beam in that portion where the web stresses exceed the allowable value of concrete in shear. Web reinforcement, unless rigidly attached, shall be placed at right angles to the axis of the beam and carried around the extreme tension member.

26. Reinforced concrete structures shall be so designated that the stresses in the concrete and steel shall not exceed the following limits.

	Per sq. in.
Extreme fibre stresses on concrete in compression ..	650 lb.
Concrete in direct compression ..	500 lb.
Shearing stress in concrete when all diagonal tension is resisted by steel	150 lb.
Shearing stress in concrete when diagonal tension is not resisted by steel	40 lb.
Bond stress between concrete and reinforcing bars ..	80 lb.
Tensile stress in steel reinforcement	16,000 lb.

Tensile stress in cold drawn steel wire used as column hoops 20,000 lb.

In continuous beams the extreme fibre stress on concrete in compression may be increased 15 per cent. adjacent to supports.

27. Axial compression in columns without hoops, bands, or spirals, and with not less than one half nor more than four per cent. of vertical reinforcement secured against lateral displacement by steel ties placed not farther apart than 15 diameters of the rods nor more than 12 in. shall not exceed 500 lb. per sq. in. on the concrete nor 6,000 lb. per sq. in. on the vertical reinforcement.

28. Axial compression in columns with not less than one per cent. of hoops or spirals spaced not farther apart than one-sixth of the diameter of enclosed column and in no case more than 3 in., and with not less than one nor more than four per cent. of vertical reinforcement, shall not exceed 725 lb. per sq. in. on the concrete within the hoops or spirals nor 8,700 lb. per sq. in. on the vertical reinforcement.

29. Axial compression in structural steel columns thoroughly encased in concrete having a minimum thickness of four inches and reinforced with not less than one per cent. of hoops or spirals spaced not more than twelve inches apart may be taken at 16,000 lb. per sq. in. on the net section of the structural steel, no allowance being made for the concrete casing. The hoops or spirals of the concrete casing shall be placed not nearer than 1 in. from the structural steel or the outer surface of the concrete. The ratio of length to least radius of gyration of the structural steel section shall not exceed 120.

30. In reinforced concrete columns the compression on the concrete may be increased 20 per cent. when the fine and coarse aggregates are carefully selected and the proportion of cement to total aggregate is increased to one part of cement to not more than four and one-half parts of aggregate, fine and coarse, either in proportion of 1 part of cement, 1½ parts of sand, and 3 parts of stone or gravel, or in such proportion as will secure the maximum density.

31. The vertical steel bars in reinforced concrete columns shall bear squarely on steel plates or castings bedded on top of the footings.

32. Bending stresses due to eccentric loads shall be provided for by increasing the section of concrete or steel until the maximum stress shall not exceed the allowable working stress.

33. Whenever it is necessary to splice bars, the connections between them shall be of sufficient strength to carry the stress.

34. In columns, the splicing of longitudinal bars having an area less than 1¼ sq. in. may be done by lapping, the lapped bars to be wired securely to each other. Longitudinals having areas in excess of 1¼ sq. in. shall be spliced by butting the bars squarely one over the other and tying the same securely together by some mechanical means that will not utilise the adhesive strength of the concrete. All such splices shall be made above floor levels, but not more than 12 in. above the same.

35. In columns the ratio of length to least side or diameter shall not exceed fifteen, but in no case shall the least side or diameter be less than 12 in.

36. The concrete members of floor construction in which hollow tiles, concrete blocks, or other fillers are used, in combination with reinforced concrete, shall be designed in accordance with these regulations, except that the slab portion cast on top of the fillers may have a minimum thickness of 2½ in. provided the fillers do not exceed 60 per cent. of the construction.

37. Exterior and interior bearing and enclosure walls of reinforced concrete supporting floor and roof loads shall be securely anchored at all floors, and of such thickness that the compressive stress shall not exceed 250 lb. per sq. in., but in no case less than 8 in. The thickness shall not be less than one-twentieth of the unsupported height. Steel reinforcement shall be placed near both faces of the wall, running both horizontally and vertically and weighing not less than ½ lb. per sq. foot of wall.

38. Footings for walls and columns may be constructed of reinforced concrete provided the working stresses for concrete and steel are not exceeded and the steel is protected by at least 4 in. of concrete.

39. The steel reinforcement in columns and girders shall be protected by a minimum of 2 in. of concrete; in beams and walls by a minimum of 1½ in.; and in floor slabs by a minimum of 1 in. of concrete.

40. The contractor may be required to make load tests on any portion of a reinforced concrete structure within the reasonable time after erection. The test shall be made under the direction of the Superintendent of Buildings, and shall show that the construction will sustain safely a load of twice the live load for which it was designed.

41. These regulations do not apply to any construction for which provision is otherwise made in the building code.

THE CHEMISTRY OF CEMENT.

With Mr. Bertram Blount's lecture on cement, which were delivered at King's College, London, on October 26th and December 1st, 1911, the Institute of Chemistry inaugurated a scheme under which Fellows who have special knowledge and experience in various branches of work are engaged to deliver lectures chiefly for the benefit of young chemists and advanced students; the object being to indicate the scope and character of the work actually carried out in various branches of professional practice distinct from purely academic training. The lecturer's opportunities of usefulness are greatly increased, although possibly the number of his actual auditors may be thereby to some extent diminished by the publication of the lectures in pamphlet form, with free distribution to Fellows, Associates, and registered students, and sale for half a crown to outsiders; but while many who obtain the books will not go to the lectures all who attend the lectures will be glad to have the books, supposing that these are at all comparable in value and importance to the one under notice. It will be found useful by all who desire to obtain—what in these days is essential to a thorough understanding of the subject—without overmuch effort or expense, a good groundwork of scientific appreciation of the properties of cement as ascertained by the methods of chemistry. Diagrams are appended.

Lectures on Cement. By Bertram Blount, F.I.C. London: The Institute of Chemistry of Great Britain and Ireland, 30, Bloomsbury Square, W.C. Price 2s. 6d.

DOVER HARBOUR IMPROVEMENTS.

The scheme for the improvement of the cross-Channel traffic facilities at Dover takes the form of a reclamation on the east side of the old Admiralty Pier as originally proposed twenty years ago. The scheme is essentially a widening of the Admiralty Pier between the shore and the turret at the seaward end of the old Pier. The maximum length of the reclamation is some 2,300 ft., with a maximum width in the curve of the Admiralty Pier of 350 ft., the width varying by reason of the fact that the seaward side of the reclamation is being constructed on a much flatter curve than that of the Admiralty Pier itself. The reclamation has been carried out by constructing a sea face in huge concrete blocks, set by divers in a foundation levelled in the chalk of the sea-bed, and filling in the space between the new wall and the pier; the filling-in operations require the use of about 1,000,000 cubic yds. of material, which is being furnished from an excavation in the east cliff at Dover where a new road is being constructed. Over the greater part of the area which has been reclaimed there is an ample depth of water, ranging up to 40 ft., and dredging operations have been necessary only at the shore end of the reclaimed site, the intention being to provide a minimum depth of water of 16 ft. at low water of spring tides. The reclamation is being carried out by the Dover Harbour Board, according to plans prepared by their engineer, Mr. A. T. Walmisley, and the site thus created is being leased to the railway company for the purposes of the new marine station.

By the coming summer the new sea wall, which will extend from the Lord Warden Hotel to near the turret, will have been finished. A part of the site has already been rendered available for the preliminary operations for the erection of the station itself, and a contract has been entered into between the South-Eastern and Chatham Railway and Messrs. S. Pearson and Son for the construction of the foundations.

Owing to the new structure having to be built on made ground, it became necessary to consider the best means of carrying it, so as to avoid future settlements; and it was ultimately decided to adopt a system of piled foundations, the piles being driven through the filling to the old sea bed beneath, and their heads connected together by reinforced concrete slabs and beams on which the new buildings could rest. Nearly 1,200 piles will be required for the purpose, and these are being made of reinforced concrete on the Considère system. A few have already been driven, and the driving of the remainder will be proceeded with as the filling progresses.

Steps are being taken by the railway company to arrange for the erection of the station to follow on the putting-in of the foundations, so that no time may be lost, and it is their intention shortly to invite tenders for the necessary steel-work and roof covering, and subsequently for the masonry, brickwork, etc., that will be required. The arrangement of the station, which is being designed by Mr. P. C. Tempest, the engineer of the South-Eastern and Chatham Railway Company, will comprise two platforms each 50 ft. wide, and about 700 ft. long, on each side of which trains can be accommodated, so that there will be room for four trains

in the station simultaneously. Waiting and refreshment rooms will be provided, and also facilities for Post Office business.

The cost of the reclamation scheme is about £400,000, and the work which is to be carried out by the railway company will probably bring the cost of the whole improvement up to a total of about £500,000.

MICA SURFACING FOR CONCRETE.

Ground mica is being used extensively for surfacing concrete work. It is said to have proved very effective for this purpose, as it gives an artistic finish to the work and adds life and sparkle to the surface, taking away the flat dead appearance that is common to concrete. About 5 lb. of mica is sufficient to cover 100 sq. ft. The electric light columns in Lincoln Park, Chicago, Illinois, were created in this way, crushed red granite being used so that the finished surface had the appearance of polished granite. The granite and mica surfacing material was applied to the inner surface of the square iron trough in which that part of the columns extending above the ground was cast. When the trough was filled, the top or lid was screwed down, pressing the concrete into all the lines and corners of the mould. After the cement had set perfectly, part of the mould was removed to permit the post to cure more rapidly. The post was not removed from the mould until it had set for 24 hours at least. After it was perfectly dry the surface was scrubbed with muriatic acid to remove the cement on the outer face of the granite and mica and leave a clean surface closely resembling that of granite.

RELATIVE MODULI OF ELASTICITY.

Commenting, in a Glasgow newspaper, upon a new departure in constructional methods that has been devised by Mr. Robert Thomson, architect, Glasgow, another architect criticised the method proposed for supplementing the strength of an existing cast-iron column on the alleged ground that "cast iron, being an inelastic material, would continue to carry the whole of the load until its crushing point was reached, when the whole load would be immediately transferred to the reinforcement." The critic proceeded to say—"If, however, the material reinforced in this manner had been steel or wrought iron (elastic materials) the reinforcing materials would have become active immediately the sectional area increased or tended to do so."

In reply to this criticism, Mr. John Sharp, Wh.Sc., M.Inst.C.E., writes: "The critic thus admits that had the columns referred to been of wrought iron or steel instead of cast iron, the encasing concrete anchored thereto would have immediately become effective, both in supplementing and in reinforcing the strength of the column, because of the elastic properties of the encased material. If, therefore, it can be shown that cast iron behaves in a similar manner to wrought iron and steel, in shortening under compressive loading, and that it has elastic properties similar to these materials, although certainly not to the same extent, the critic must perforce include cast iron with wrought iron and steel, and thus admit the soundness and efficiency of Mr. Thomson's method."

"From a long experience in working and testing cast iron, wrought iron, and steel, it would be easy to satisfy the critic regarding the elastic properties of cast iron; but it will be interesting," Mr. Sharp thinks, "to refer to the highest recognised authority on the subject. I therefore suggest that those interested should consult Professor Unwin's book on 'The Testing of Materials of Construction' (1899 edition). In this book they will find the stress strain diagrams of cast iron and steel alongside each other. From these it will be seen that the shortening of cast iron under compressive loading is nearly twice as great as that of steel, and that therefore the concrete encasing a cast-iron core must of necessity actually take a greater portion of the load than it would were the core of steel or wrought iron. The relative stress and strain in the metal and reinforcement depend on the relative moduli of elasticity and the proportions of the materials employed."

LEGAL.

A Question of Soil-Pipes.

At Marylebone Police Court Mr. White, chairman of the London County Council, was summoned by the borough council for putting into his house at 21, Upper Berkeley Street, W., a soil-pipe which was not all lead.—Mr. Freke Palmer said that the proceedings were taken under by-laws of the London County Council.—Mr. White said he was very angry at being dragged into a criminal court. He had been marked out by the borough council because of the position he held.—Dr. Porter, medical officer, replied that several other offenders in the same way had been compelled to substitute lead for iron soil-pipes.—Mr. White complained that he had also been robbed of his right of appeal to the committee of the London County Council, of which he was chairman.—Mr. Plowden thought the soil-pipe was half inside and half outside the house, and there was nothing in the by-law which provided for such a pipe. It was really a drawn battle. Each side was right, and each was wrong; and Mr. White left the court without a stain on his character. He was fined a nominal penalty of 10s. for not having deposited the plans with the borough council.

Liability for Accident.

In the King's Bench Division last week, before Mr. Justice Coleridge and a special jury, an action was tried in which Mr. Alfred Goulton Padbury, a commercial traveller, sought to obtain from Messrs. Holliday and Greenwood, builders, of Brixton, damages for personal injuries. It appeared that on January 4th, 1911, plaintiff, while passing a building that was in course of erection in Fenchurch Street, London, was struck on the head by an iron cramp that fell from the third floor. For eight months he had been unable to follow his occupation, and his memory and eyesight had been seriously and, it was feared, permanently impaired.—Defendants denied liability, and urged that the cramp was dropped by the employee of a firm of sub-contractors, for whose accidents the defendant firm were not responsible, and in whose selection for the work they had no choice.—The jury, however, awarded plaintiff £500 damages.—Judgment accordingly, with conditional stay of execution pending a possible appeal.

OBITUARY.

Alexander Graham, F.S.A., F.R.I.B.A.

Mr. Alexander Graham, whose death we greatly regret to announce, was for ten years (1899-1909) hon. secretary of the Royal Institute of British Architects, of which body he was vice-president from 1893 to 1897. He was the architect of the Sandlebridge Colony for Epileptics, Cheshire, which cost about £60,000, and noteworthy among his numerous works are the Montreal General Hospital; warehouses for Welch, Margetson, and Co., in Moor Lane; Law Guarantee Society's buildings at Buckingham Gate; and the Armourers' Company's premises in Drapers' Gardens, E.C. Of late years he was frequently appointed assessor in competitions; and his water-colour drawings showed an unusual degree of accomplishment.

At the R.I.B.A. meeting on February 10th, the hon. secretary, Mr. Henry T. Hare, read the following letter from Sir Wm. Emerson:—

"19th Feb., 1912.

"DEAR MR. PRESIDENT,—I very much regret my inability to be at the meeting this evening to express as I would wish my own personal sense of loss at the passing away of our old friend Alexander Graham, and to join in the tribute of respect and esteem that will be paid him, not only by his former colleagues on the Council, but by the numerous body of members who knew and appreciated his sterling qualities.

"A steadfast supporter of the Institute, he was from the first one of the most active and zealous of its workers. During my term of office as Member of Council, as Hon. Secretary, and afterwards as President, I had frequent opportunities of observing the high-mindedness and disinterestedness he displayed in all that he did for the Institute. A man of the strictest probity and integrity, he placed the honour of the profession and the well-being of the Institute before everything; to preserve the one and secure the other he would count no personal sacrifice too great.

"Mr. Graham, when he was elected Hon. Secretary, must have been nearly approaching his threescore years and ten, and though at that age his conservative tendencies were somewhat strongly pro-

nounced, he was never intolerant of the views of those who differed from him. As I remember him at the Council meetings, he spoke but seldom; and if he was a little lacking in initiative when some necessary movement was in question, when once a course of action was decided upon, he would devote himself to the work expected of him with all the zeal and thoroughness of one many years his junior.

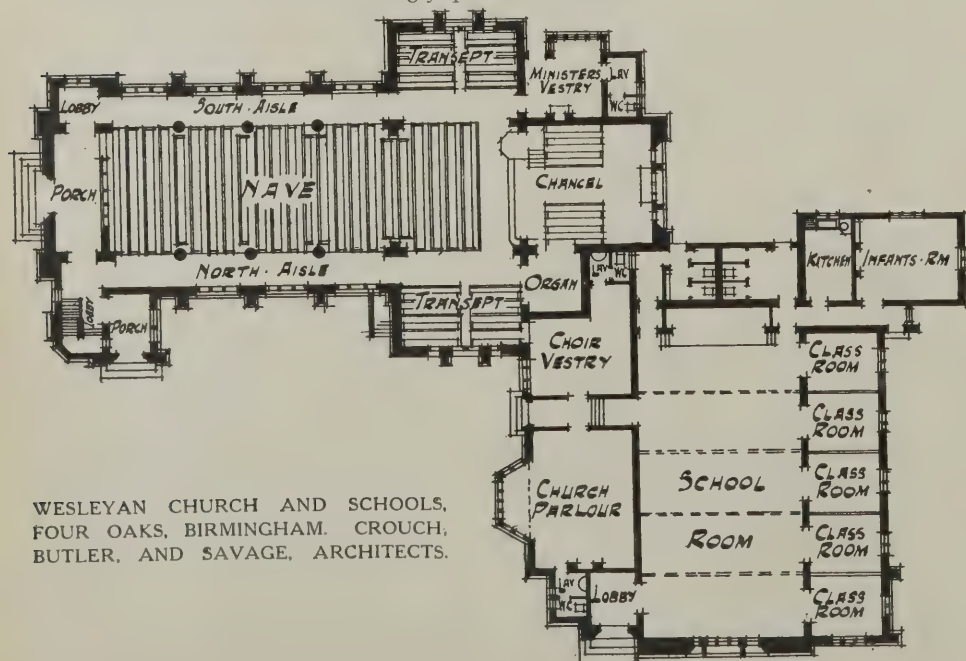

"His courtesy and urbanity of manners were familiar to us all; no one could discharge with greater distinction the various public and social functions that fall to the lot of the Honorary Secretary of the Institute. He was true and sincere in his friendships, ever sympathetic and warm-hearted, and one of the cheeriest and most agreeable of companions. I know personally that not a few young architects have cause to be grateful to him for his kindly advice and assistance.

"For myself I deeply deplore his removal from us, and beg to be permitted to associate myself in the resolution to be moved this evening recording our sorrow at the loss we have sustained and our sympathy with his relatives.—Yours faithfully,
"WM. EMERSON."

OUR PLATE.

Wesleyan Church and Schools, Four Oaks, Birmingham.

This church is built on an excellent site at the junction of the Lichfield and Walsall Roads. The nave was erected some five years ago; and the whole scheme, including schools and caretaker's rooms, has now been completed. The church consists of nave, transepts, choir, and organ chamber, with a gallery over the western porch. A lofty tower marks the crossing. The pulpit and the fittings generally are of oak, carried out to the architects' own designs. The east window, representing Christ blessing little children, is by Messrs. Harvey and Ashby, of Birmingham. The stone used was from Weldon, Northamptonshire, except that for the piers, which is grey Forest of Dean. The roofs are covered with Colley Weston stone shingles. The adjoining school buildings consist of assembly hall, church parlour, and infants' room. The total cost has been £11,000. Messrs. Crouch, Butler, and Savage were the architects.

WESLEYAN CHURCH AND SCHOOLS,
FOUR OAKS, BIRMINGHAM. CROUCH,

SEVENTH MANCHESTER BUILDING
TRADES EXHIBITION.

At the Midland Hotel, Manchester, on February 15th, Mr. W. Cawood presided at a meeting of the exhibitors of the seventh Manchester Building Trades Exhibition, which will be held at the City Exhibition Hall, from March 5th to the 16th.

It was announced that Councillor S. W. Royse, J.P., Lord Mayor of Manchester had consented to open the exhibition at 12 noon on Tuesday, March 5th, and that Alderman J. R. Wilson, J.P., chairman of the Manchester Improvements Committee and Town Planning Committee, had consented to take the chair upon that occasion.

Resolutions dealing with the Reception Committee, and the names of gentlemen to propose and second various votes of thanks, were duly carried. It was announced that telephones at the special rate of £1 each could be affixed to the various stands, thus permitting the exhibitor to telephone from his own stand at the City Hall to his works. This charge is one-third of the charge usually made at exhibitions. Another interesting item was the printed list showing the special railway facilities from towns within the radius of 100 miles from Manchester to the exhibition.

A number of other resolutions were passed, and the chairman was specially thanked for the manner in which he had always given exhibitors the opportunity of taking part in the direction of exhibitions under his control.

The Chairman announced that more exhibitors had booked space this year than for any previous exhibition of this series, and that there was every prospect of the seventh Manchester Building Trades Exhibition being a record success. More than seventy firms are now included in the list of exhibitors.

Builders' Clerks' Benevolent Institution.

We understand that Mr. Dudley Bartlett, who is president this year of this Institution, is organising a theatrical performance in aid of the funds. This is to take place at the Royal Court Theatre, Sloane Square, on the evening of Saturday March 9th. The play to be presented is Bernard Shaw's "You Never Can Tell," and as it will be interpreted by that well-known dramatic society "The Strolling Players," a good entertainment is assured. Tickets, which range from 2s. to 10s., may be obtained on application to Mr. Dudley Bartlett at Tredegar Works, Bow.

Mr. E. S. Prior Elected Slade Professor at Cambridge.

Mr. Edward Schröder Prior, F.S.A., F.R.I.B.A., was on February 20th elected Slade Professor of Fine Art in succession to Dr. Waldstein, resigned. The new Professor was born in 1852, and was educated at Harrow and Caius. He was a pupil of Mr. Norman Shaw, R.A., and has been architect to Cambridge University, where he designed the building in which the present Medical School is housed, to Harrow School, and to Winchester College, and has built churches and houses in many parts of England. Mr. Prior was one of the founders of the Art-Workers' Guild, and has been secretary of the Arts and Crafts (London) Exhibition Society since 1902. His publications include "A History of Gothic Art in England" and book on the Cathedral-builders and the medieval figure-sculpture of England.

The Institute and the Society of Architects.

THE meeting at the Institute rooms on January 8th to consider the proposed amalgamation of the Society of Architects with the Institute was, officially, a private one, and therefore we made no comment on it at the time except to record the result of the voting, and to congratulate Mr. Gibson on the speech which he made in bringing forward the proposals of the Council; one of the best speeches, certainly, that have ever been heard at an Institute meeting. That the rejection of the proposals (or, to speak more precisely, the amendment to refer them back to the Council for further consideration) should have been carried by a very large majority was not at all events due to any want of ability in the way in which they were brought forward. Since then it seems to have been judged right that the members at large should have the full report before them of what took place; this has now been published in the current issue of the Institute "Journal," and is therefore practically public property.

We fear the perusal of this report can leave no doubt that the Council made rather a serious mistake in the details at least of their policy, though, in the main, it was doubt intended for the best. Seeing that a majority of the profession were obviously in favour of a Registration Bill, it may have seemed, logically, best for the prospects of such a Bill that the two bodies should take united action. But the initial mistake was to formulate a draft Bill and make it an integral part of the proposal; to say to the Society of Architects—If you will put aside all opposition and join our ranks, we will engage to bring forward in Parliament a Bill as here set out. For some of the proposals in the Bill are such as Parliamentary assent would never be secured for. One is that every public body, committee, or trust "who shall hereafter erect or shall alter the exterior of any building facing any road or open space at a cost exceeding £1,000 out of funds supplied or provided by public grants, rates or other assessments, shall employ or appoint an architect as herein defined," &c. This, in fact, would be a Bill brought forward by the representative body of the profession to compel public bodies to employ one of their number. For architecture might be a very good thing that it should be so ordained, but it would arouse the opposition of every public body in the country, who would have far more power to make their influence felt in Parliament than any influence the representatives of the architects could bring in opposition to them. To legislate that no one should practise for hire or reward in designing a building unless he is an architect within the definition of this Act (Clause 4 of the draft Bill) is one thing; to attempt by law to dictate to all the public bodies in the country as to whom they should employ on their work is quite another thing. But what follows in the succeeding clause is still more impracticable: that in the case of bridges and similar structures primarily of an engineering character "they shall employ and appoint an architect to collaborate with the engineer in the design and supervision of the façade or exterior of the said buildings." Just imagine Parliament being asked to pass a law that effect! The idea is almost comical. It would be

a very good thing, no doubt, if this were done always; but it is a kind of improvement which can only be brought about by the influence of an educated public opinion, which has already had some little effect in that direction. But for the architects to come to the Government and say—Please pass a law that one of us shall always be employed to help an engineer in designing, would merely expose them to ridicule in the eyes of the legislature. Mr. Gibson said in his speech that the Institute did not want a nebulous shadowy measure which would govern nobody; they wanted to promote such a Bill as would practically enable them to control all the architects in the country. That is within their logical rights, but not a Bill to control all kinds of other corporate bodies outside the profession.

From the speeches made in opposition, it is obvious that the terms of amalgamation held out to the Society of Architects had caused serious dissatisfaction to many members of the Institute. One hundred members of the Society (not more than one hundred is the way it is put) were to become at once Fellows of the Institute on the mere recommendation of the expiring Council of their own body, without any other consideration. Considering that Fellows at present are either elected from the ranks of the Associates who have passed an examination, or are elected by the Council on account of their possessing eminent qualifications as architects, it is hardly to be expected that the present body of Fellows and Associates would regard such a sweeping proposal with approval. There are other points in the arrangement besides that, which we need not go into, but the collective effect of which certainly is that the terms of amalgamation are such as would be in every way to the advantage of the Society of Architects and by no means to the advantage of the Institute.

As Mr. Stanley Peach put it, in moving the amendment to the Council's proposals, why should the Institute go thus far out of its way to disarm the Society? The Institute is a powerful body possessing a Royal Charter, in a strong financial position, and with a very large membership. "What chance," said Mr. Peach, "would the Society of Architects have in opposing the Institute, or in proposing that they should be the Diploma Authority instead of this Institute? I do not believe that any Parliamentary Committee would consider that for a moment." And when we come to speak of the Charter, there is another serious question, which was raised by Mr. Sydney Perks, the seconder of the amendment. The Institute obtained a fresh Charter in 1887, for certain purposes, and another in 1909, and now it was proposed to ask for another in 1912. Mr. Perks quoted the opinion of one who, he said, was well able to advise on such a point; the opinion was that "the proposal to take in a Society of a certainly inferior position to your own would mean that you would be extending the privileges of the Royal Charter to a body without one, and that is a very serious thing for you to contemplate. It might lead to an enquiry, and it is not a good thing to have an enquiry about a Charter." Those are the words of common sense, and it is surprising that the point does not seem to have occurred to the Council of the Institute. It is certainly not to the advantage nor to the dignity of a body with a Royal Charter to be constantly asking for alterations and extensions to its terms.

One cannot, of course, be surprised that the Society of Architects, when invited to efface themselves as a separate

body, should have proposed the most advantageous terms they could for themselves; that is perfectly natural from their point of view, and they cannot be blamed for it. But the concessions made by the Institute were hardly in accordance with its own dignity or with full regard to the status of its own members, and one cannot feel any surprise at the opposition that has been aroused among its own ranks. The proposals have been referred back for further consideration; but our impression is that we shall not hear any more of the amalgamation scheme.

Some Points of Difference with Professor Lethaby.

A SMALL book on architecture by Professor Lethaby* raises some points of interest which we desire to take up with the distinguished author. First, let us say that Professor Lethaby was just the man to write such a book, as far as grasp of the subject is concerned, the extent and universality of his historical information being apparent on every page. Whether the result is very clear for the ordinary reader may be another question. The author is a little too much given to expressing himself in conundrums, so to speak, and he has ideas and opinions of his own in regard to architecture which, however interesting and suggestive in themselves (and they rarely fail to be so), would not in all cases be generally accepted as representing a normal view of the subject discussed. We can hardly agree, for instance, that the eastern form of the tall semi-ellipse in a dome or arch, "when we become accustomed to it, is seen to be the most beautiful form of arch, for it is the most perfect and scientific." Very few people will agree with that opinion, and it should hardly be stated as a normal conclusion in what is intended as a rudimentary book for giving a general idea of architecture to beginners in the subject. So far from its being the scientific form of arch, it arose from the naïve attempt of primitive builders to close over the walls in the only way in which they could manage it without centering built up from the floor—leaning them inwards as far as the adhesive quality of the bricks or mud (what engineers call their coefficient of friction) would allow with safety, and then closing in the top on a light centering; for centering there must have been for that part of it. That a dome of this shape, viewed from inside, would be seen to be the "most beautiful" by the majority of persons, and preferred to the grand sweep of a semicircular dome, is a mere paradox. The method by which arched vaults were built in Assyria without centering, by leaning each ring of the arch sloping backwards and making the voussoirs of the next ring adhere to it till the ring was completed, is referred to as if it were an ingenious method of arch construction whereas it is an exceedingly clumsy one, and cannot be carried out on a large scale; that is undoubtedly the reason why the Assyrian palaces are planned almost entirely in long narrow rooms. Then it is surely giving the amateur reader a very false impression of facts to say that every modern arch, so far as it is made homogeneous by cement, "is in a sense a bent beam—that is, the wedges do not act separately." That may be true "in a sense," but nevertheless the arch with wedge voussoirs would stand without any cement, granting that there was no movement or settling of the foundations; the cement is really only a safeguard against that.

In short, in all these passages about the arch the reader is rather encouraged to believe that unscientific expedients of primitive builders represent the normal and true method of arch-building; and what is at the bottom of this is evidently the author's predetermination to represent all architecture as merely the development of primitive building. It is impossible, he says, to differentiate architecture from building. It is extremely difficult, we grant, to frame a definition in words to express the difference, but it is one that we can all perceive in our minds, however difficult to express in words. To a certain extent this view of architecture is a wholesome one, and it brings forward the great interest which there is in all problems of building;

but it is going too far to deny to architecture the influence of intellectual choice. In his anxiety to do this, the author slightly speaks of the optical refinements, what we may call the concealed curvatures, in Greek buildings, saying that they are most natural and need no explanation; "curvature of lines furnishes an intermediate between the straight and the rounded." That does not apply to curvatures which were not meant to be seen, which were only made to prevent a false appearance of curvature. The idea was an outcome of the exceedingly refined perception of the Greeks of the great period, and by no means a "natural" idea, or why is it that we only find it with the Greeks? The Roman columns with their *visible* entasis are not a case in point at all. The assertion, referred to on page 64, that lines in the plan of some of the Egyptian temples are laid out in a just perceptible curve, has no certain foundation. Pennethorne asserted that he had found it in one temple; but as these "just perceptible" curves were not the same on both sides, and were discovered on the inside lines only of a quadrangle, the probability is that they were merely the result of a slight settlement. We quite agree, however, in the remarks on page 96 as to the wasted efforts of those who have attempted to deduce systems of proportion from the measurements of Greek temples. As the author says, the student is set on evolving some scheme of measures in the modulus of the diameter (of the column); "if it did not fit, he added on a foot or two, and said it must be so." It is perfectly true, and the same remark applies, even more strongly, to the efforts that have been made to prove the existence of a fixed modulus of proportions in Gothic buildings. They never will fit properly.

The nature of Gothic architecture is very graphically characterised as essentially "a problem in equilibrium." That is the great difference between Gothic and all other arched styles, except that we may perhaps call *St. Sophia* a problem in the equilibrium of domes. "The builders made an effort to do all that might be done in stone, and the possibilities of rearing stones one upon another were explored to the utmost." But, nevertheless, the reader ought not to be allowed to think that the problem of construction was everything. Imagine the most ingeniously balanced Gothic cathedral deprived of its mouldings and tracery and carving; would it then be the same great work of art? It may be added that in some of the French cathedrals the art of balancing thrusts was carried a great deal too far for the best architectural effect, making them look like pieces of stone scaffolding, externally.

We can hardly be surprised, of course, to find the author speaking rather contemptuously of the Renaissance period as the age of "architects' architecture"; it is to him "a style of boredom." We cannot find it so, nor is this, we believe, the general feeling now. But he admits that the Renaissance age had the great gift of the scientific spirit, and that we probably owe to it "larger ideas of civic order and hygiene"; which is something, at all events. And he admits (and we agree with him here) that while on the one hand the Renaissance was a rhetorical art, on the other hand "its artists to some degree considered first principles":—

"To go back to first principles in architecture is, we are often told, impossible. Doubtless it is to do so absolutely, but all schools of architecture have done it in some degree, and the Renaissance, in the thought of the greatest mind of its age, was to include an exhaustive exploration of the first principles of all arts. The history of art is full of instances of return to underlying principles."

With the concluding chapter, on "The Modern Position," we are more fully in agreement than with any other portion of the book. All modern buildings, says the author, "have too much that is merely capricious"; and if by modern buildings is meant those of the last decade or two, surely this is only too true. Architecture has become too largely a thing of quips and cranks, the interest of which will be gone in another generation. As Professor Lethaby says, an expressive form of art is only reached by building out in one direction for a long time; "no art that is only one man deep is worth much; it should be a thousand men deep." And he urges us to seek agreement on a scientific

* "Architecture: An Introduction to the History and Theory of the Art of Building." By W. R. Lethaby, London: Williams and Norgate, price 1s.

basis, on an endeavour after perfect structural efficiency, in the faith that, such agreement being reached, beauty will take care of itself. It will, provided there is a general, a public desire for it. That is what is really needed; a demand for great architecture. There is little enough of that at present. It is not genius, the author thinks, that is lacking. "An age that can produce Watts's 'Physical Energy,' Madox Brown's Manchester paintings, and the Forth Bridge, should be able to produce anything—anything, that is, except the Tower Bridge as well." We feel obliged to differ about the Manchester paintings, but otherwise the sentence is admirable, especially the satiric "except" at the close; and we recommend the whole of this concluding chapter to the attention of architects and general readers alike. The historical part of the book must be taken with much reservation, because it is permeated by the attempt to make history serve a special theory as to the non-intellectual origin of architecture, leading to such statements as that the dome of the Pantheon, with its central opening, "is the last word in the development from the primitive hut into which light entered by the same opening from which the smoke escaped." The dome of the Pantheon would have been built as it is if there had never been a primitive hut in the world.

The Royal Gold Medallist.

MR. BASIL CHAMPNEYS, who has been nominated for this year's Royal Gold Medal "for the promotion of Architecture," is chiefly known as the architect of several collegiate buildings at Oxford and Cambridge, and of the Rylands Library at Manchester. At Cambridge his work includes the Divinity and Literary Schools, Clough Hall, Newnham College, the Archæological Museum, and All Saints' Memorial, while at Oxford there are to his credit the Indian Institute, Mansfield College, and new buildings at Merton, New, Oriel, and Somerville. He also designed the Butler Museum at Harrow, the Quincentenary Buildings at Winchester College, the Grammar School at King's Lynn, and numerous churches, among the last named being St. Luke's, Kentish Town, and St. Mary Star of the Sea, Hastings. Mr. Champneys was born in 1842, and is therefore now 70 years of age. His father was Dean of Lichfield.

MR. BASIL CHAMPNEYS,
Who has been nominated for the Royal Gold Medal.

The True Hope for Architecture.

WHEN Mr. Eden read his exceedingly clever and amusing paper at the Architectural Association last week on "Hopes and Fears for Architecture," he was twitted by one of his audience afterwards with having brought before them far more "fears" than "hopes"; and there was some truth in this playful criticism. There are so many points in connection with architecture as practised at the present time which lend themselves to a satirical treatment on the part of an author with a capacity for putting things neatly. As Touchstone says in the play: "We that have good wits have much to answer for; we shall be flouting; we cannot hold." But flouting, however amusing for the moment (and it is something that a paper on architecture should be amusing; they are not always), does not carry one much further. We confess that in reading Mr. Eden's paper over again we have found it rather difficult to discover where his "hopes" are. The first glimmer of light we come to is the assertion that every passing phase (in the recent fashions of architecture) has left some good behind it. In the case of the Gothic Revival, this is certainly true of one of the benefits claimed for it; it left an example of enthusiasm, without which much cannot be accomplished. There was a real, a burning enthusiasm about the chief apostles of that revival; an enthusiasm which was communicative, and influenced most of those who were the younger generation at that time. There does not seem to be anything like such enthusiasm for architecture at present, and that is a serious want. Mr. Eden's other claim for the Revival, that it arrived at establishing definite principles, we fear will not hold water, because a good many of its principles are now perceived to have been false. The "Seven Lamps" retains its value only for its enthusiasm, not for its principles, unless it is claimed that it set a good example in endeavouring to formulate principles at all. But we do not know that much good has ever been done to architecture by discussing principles. It is rather chilly work.

The next "hope" that we can find is that the knowledge of architecture among educated people has made great strides during the last thirty years. It has improved somewhat, no doubt, but it has not got very far as yet; we certainly do not possess yet a public in this country who are earnestly desirous of having great architecture, and that is one of the greatest desiderata. As Lord Leighton said many years ago—"What the public want, that they will have." If the public earnestly desire great things in architecture, and think them worth paying for, such great things will be likely to be forthcoming. But there is little evidence of such a want at present.

The next "hope" that we can find is only quoted from another source, and there is nothing to show that the author of the paper believes in it. A lecturer had said that architecture must be living, must find its poetry in the life and its inspiration in the opportunities of the present; "are we not building every day," he said, "hotels, railway stations, asylums, baths and wash-houses, and abattoirs?" But we do not gather, from the spirit in which the reference was made, that the author of the paper found much comfort in these sources of inspiration.

The only other "hope" we can detect is that we have made some progress in one particular—namely, sympathetic and, as far as possible, traditional treatment of material, involving as it does both texture and colour. There has certainly been an improvement in that respect; we have developed an eye both for colour and texture, though we hardly think that this element of improvement goes as near to the root of good architecture as Mr. Eden seems to imply.

These are all the "hopes" we have been able to find after a careful reading of the paper; and for a paper which was long, though never dull, they do not seem very abundant. Let us try to be a little more optimistic.

There are two main influences which may aid in once more evolving great architecture among us. One, which we have already referred to, is enthusiasm, a real and keen interest in the subject, on the part both of the public and

the architects. The enthusiasm of the public has not as yet gone very far; in fact, there is as yet nothing to call forth enthusiasm; but there is a greater interest in the subject than there used to be; and we hope that interest, having begun to grow, may go on increasing. Without that the architect, however enthusiastic he may himself be, can hardly get his opportunity. The other hope for architecture, and one which concerns only the architect, would lie in nourishing the perception that architecture is not, as Mr. Eden put it (we can hardly think quite seriously), "only skin-deep"; that a true architectural treatment lies in the perception that a building is primarily an idea worked out in plan, in structure, and in mass, and not a mere matter of suitable, or sometimes unsuitable and capricious, surface detail. If an architect will only begin by thinking—How can this building best be disposed in plan to suit its practical purpose? next, How can it best be constructed and express its structure? and lastly, How can its general mass be most effectively disposed? he will have come near to producing a real and interesting piece of architecture, wholly apart from any question of detail. Detail is very important, no doubt; it is the quality which imparts refinement to a building; but it is not what makes architecture. It is the plan, and the disposition of the masses, that make the Houses of Parliament a great building; not the late Gothic detail, which is overdone and perhaps not quite so good as it might have been. The detail might all be altered, and it would still be a great building. Reynolds, in his Lectures on Art, drew particular attention to this quality in Vanbrugh, whose detail was certainly not very good; he always, said Reynolds, disposed his masses finely; a point that would naturally strike a painter. Now there are some lessons on this in American architecture. Referring to Mr. Eden's rather bantering reference to baths and wash-houses, and such buildings, as sources of inspiration, we find that some of the American architects do manage to make buildings of a merely utilitarian character architecturally interesting, merely by the disposal of mass in an effective manner. Or, to go to higher things, take a building which was referred to in the lecture under consideration,

the villa at Caprarola. The architect of that was one of the great authorities of his day on the Classic Orders, and issued elaborate publications on them, and he applied the Classic Order on the five faces of his famous villa. But it is not the treatment of the Orders that makes Vignola's Villa a celebrated building; you might find that as well done on fifty other Renaissance buildings. It is that the plan and conception of the building are strikingly effective and original; it represents a distinct *idea* in architecture. A true hope of architecture would lie in having more of that spirit in the treatment of buildings.

Another element that is very much needed is a larger and ampler treatment of modern architecture; everything is too small and timid with us in this country; but to have even the chance of that we must have a public ambition for great architecture. How came it that Poelaert was able to produce at Brussels a Law Courts building of such amplitude and dignity, far beyond what has been done in our much larger and richer capital? Because he worked for a Government that believed in great architecture, and thought it worth paying for. We cannot, unfortunately, command that from our own Government; the only hope is that there is some little progress in the last few years, in English public interest in architecture. Let us hope it may increase and do all we can to foster it.

The Old Town Hall, Manchester.

IN its old Town Hall in King Street, Manchester possesses a really fine piece of architecture, designed by Francis Goodwin, and dating from the first quarter of the nineteenth century. Well, therefore, is a public subscription being raised to save its noble façade; for the building, latterly used as the Reference Library, is to make way for a bank, the design of which, let us hope, will be worthy of the site. It appears that the cost of the building when opened in 1825 was £40,000, inclusive of site, whereas, when the arrangement for its sale was made nine years ago, Lloyd's Bank agreed to pay £161,750, which

THE OLD TOWN HALL, MANCHESTER (TILL LATELY THE REFERENCE LIBRARY), AS IT WAS IN 1866.

THE OLD TOWN HALL, MANCHESTER, AS AT PRESENT.

is one more example of how the value of property grows in the centre of a city.

As the time approached for the Bank to take over their purchase, it became evident that unless something was attempted for the preservation of the façade all visible record of Manchester's finest example of architectural design would be irrevocably lost. A proposal was therefore set on foot with the object of removing the façade to one of the parks of the city and there re-erecting it. To this proposal the Manchester Society of Architects gave its hearty support, the president, Mr. Edgar Wood, F.R.I.B.A., observing that "it would be for ever an interesting monument of the city history, showing a high standard of architecture attained at that time, of which any city might be justly proud. To the continuous stream of architectural students of the School of Architecture, which is a part of the Corporation scheme of education in conjunction with the University, this would have a real practical value for detail study and measurement. If the façade were re-erected with surroundings carefully selected combining foliage and water treatment, it would always be a source of educational value and æsthetic pleasure to the public, and would support the work and intention of the Art Gallery and the School of Art. We cannot urge too strongly that this is a rare example of the highest standard to which architecture has attained, and the Manchester Society welcomes the opportunity to offer such help for its partial retainment as lies in their power."

Two possible schemes have been suggested. The first is for the re-erection of the whole façade, including the covered loggia; this would cost about £2,300. The second is for the re-erection of the colonnade only, without backing; this would cost about £1,300. In either case the Parks Committee will only proceed with the scheme if half the amount required be raised by public subscription. It is to be hoped therefore that the efforts of the "Manchester Guardian" in attempting to raise the sum needed to preserve the work, either entire or in part, will meet with success.

We show here some photographs of the exterior as it was in 1866 and as it is to-day, from which it will be seen that the appearance of the building has suffered not only from the sooty atmosphere of Manchester, but also from some street-widening scheme of which we have no knowledge, but which has shorn the building of some of its steps, as well as the podium wall and its pedestals. For these exterior views and for the interior of the Reference Library we are indebted to the Chief Librarian; while Mr. John M. Macfarlane has kindly supplied us with a detail photograph of the colonnade. The building, of course, was never designed for use as a library, and the filling of its walls with bookshelves destroyed much of its architectural character, as became apparent when, a week or two ago, the library contents were removed to temporary premises in Piccadilly, and the empty rooms regained their original aspect. At the time of writing the housebreakers are

about to start the work of demolition, but there seems to be every hope that the scheme for the preservation of the façade will be successful.

A Fair Wages Clause.

A REVISED fair-wages clause for building contracts was the subject of a long and an animated debate at a recent meeting of Portsmouth Town Council. In most of its provisions the clause follows ordinary precedents, but the local master builders' associations opposed it on the ground that certain departures from the common form are obnoxious. It is provided that "proper books should be kept by contractors, giving hours and wages of employees, and be produced for inspection by any member of the Town Clerk's staff when required," and that "the contractor should give assurances that during the three months immediately preceding the date of his tender for the contract he had paid the recognised rate of wages and observed the conditions agreed to, or, in any trade where such rates did not exist, the contractor should, for the same period, have paid wages and observed conditions equal to those granted by the best employers in the same business in the district, or in any district, in which the workmen may be engaged." The Portsmouth master builders' associations doubtless referred to these points in the written protest in which they declared that the clause was "calculated to tamper with the freedom of their business," and that "the Council had no right to interfere with contracts other than public ones." They further objected that the penalties for breach—determination of the contract, or £500 as liquidated damages—were "most unjust to employers." Exception was taken by one of the speakers in the Town Council to the provision that the contractor must not "prohibit his workpeople from joining trade societies or continuing to be members of such societies." Ultimately the report was referred back, that "the clause might be amended so as to render it acceptable to both employer and employed." It will be a very cunningly devised clause that will produce that effect; but revision ought at least to get rid of the very objectionable demand for inspection of the contractor's books; and the money penalty for breach, if retained, should be either reduced to a reasonable sum or, preferably, left to be defined by an independent arbitrator. To allow a corporation power to decide what sum it will award itself by way of damages is not less ludicrous than unjust.

THE REFERENCE LIBRARY INTERIOR, 1878.

THE PROBLEM OF THE RESTORER.

At the third meeting of the session of the Edinburgh Architectural Association, Mr. William Davidson, vice-president, delivered a lecture on "The Restorer and his Attitude towards Old Work." The chair was occupied by Mr. J. B. Dunn, F.R.I.B.A., president.

Mr. Davidson, who dealt mainly with ecclesiastical restorations, opened his lecture by dividing restorers, generally, into four classes—viz., historical, antiquarian, æsthetic, and ritualistic. The attitude of each was described. The lecturer stated that for the ideal restoration all four stand-points must be considered; and while a profound reverence and veneration must be felt for all existing beautiful old work, it must be remembered that a church must be suitable for its purpose as a place of worship, and not considered merely as a sanctified museum; utility, comfort, and beautiful composition being absolutely imperative. The architect should not make the restoration an opportunity for the display and glorification of his own personality, at the expense of the history of building, but at the same time a sentimental zeal for the work of the dead should not prevent him from creating a beautiful and perfect unity where such was possible.

Mr. Davidson referred to some recent interventions of "antiquarian" and "protection societies," and maintained that the craze for preserving past history, if carried to its logical conclusion, would lead to a dead stop in the architectural history of old buildings which, if occupied for their original purpose, still had a living history.

He admitted, however, that unused ruins, such as Holyrood, Linlithgow, Melrose, Fountains, Kirkstall, etc., were, as a rule, best only carefully preserved and not restored. We also, he said, have a history to record which is, as a rule, more beautiful than much of the seventeenth, eighteenth, and nineteenth centuries' history.

Many views were shown of restorations by Sir Gilbert Scott, Bodley, Oldrid Scott, Temple Moore, Micklethwaite, Weir, Carøe, and others, which were analysed and criticised. These consisted mainly of abbeys and parish churches, and illustrated various methods of restoring stonework, woodwork, glass, etc. Additions to old buildings such as chapels, vestries, towers, and the introduction of organs and new furniture, were dealt with in detail, and the merits and faults of various systems discussed. The principles and practice of the Society for the Protection of Ancient Buildings were fully treated upon, and while the lecturer spoke in the highest terms of their work, which had saved to us many priceless gems of mediæval art, he considered that they too much ignored the æsthetic side of the question. Their "no-repeat-of-old-detail" policy had destroyed the scale, proportion, and beauty of many fine old churches.

The introduction of plain blocks instead of repeating old moulded work in wood and stone brought in a new scale which in many cases destroyed the unity.

Many examples of the work of the Protection Society's architect, Mr. William Weir, were shown, and Mr. Davidson spoke in the highest terms of much of Mr. Weir's work, which always showed a profound knowledge of the subject and reverence for the beauty of old work.

Mr. Davidson maintained that the work of the best craftsmen of to-day in stone, wood, plaster, glass, etc., quite equalled that of the fifteenth century, and he believed that with our present general tendency to return to first constructive principles, the day was rapidly dawning when, by the help of decorative and applied art, architecture would again become the glory and pride of our country, as it had been in mediæval times. In speaking of additions to old buildings, the lecturer agreed that they should not be merely copies of existing parts of the building. They should speak their history unmistakably, but the great feature to be noted was, that if the scale of the original work was good, it should be carried out in the new work. Examples

from the cathedrals of Florence and Chartres were shown to illustrate this point. The restoring of hammerbeam roofs and rood screens was shown by fine examples from Norfolk and Suffolk. In speaking of restoring glass, some excellent examples were shown from Chartres, Winchester, York, Norwich, etc. He agreed that no new glass should be introduced among old. Better a small pane of old kaleidoscopic fragments in the centre of plain old Dutch square or diamond panes, as was so beautifully done by Mr. King, of Norwich, under the supervision of Mr. Weir, at the east window of St. Peter's, Hungate, Norwich, than any more or less speculative attempt to complete the design.

In speaking of painting, Mr. Davidson observed that figure painting especially was such a personal work that any attempt to restore it rendered it absolutely valueless, even when done by the most sympathetic and able of artists. In purely geometric or floral work it might be done fairly successfully, as was seen at the chancel roof of Southwold, which, though repainted twice (he believed), still retained much of the mediæval feeling. Figure wall painting, as at South Burlingham, Potter Heigham, etc., and the work on the rood screens, should never on any account be touched up or restored, but should be carefully treated for preservation by an expert if they showed signs of decay.

The rebuilding of the Campanile at Venice was referred to as a piece of misplaced sentimentality.

In concluding his lecture, Mr. Davidson stated that no hard-and-fast rule could be drawn up for the guidance of the restorer, but he must possess a profound knowledge of old work, the uses of various types of plan, a thorough grasp of the evolution of design, a deep reverence for all beautiful old things, and be filled with unbounded enthusiasm for each work entrusted to his care—an enthusiasm which leads to a non-personal view of each individual problem—and who will be more jealous to preserve any real beauty of bygone years, than make its destruction an excuse for the display of his own personality and ability, but who will not at the same time sacrifice glorious opportunity for a mere sentimental zeal for the preservation of the work of the dead.

At the close of the lecture a keen discussion took place, in which Mr. John Watson, F.R.I.B.A., Mr. J. B. Dunn, F.R.I.B.A., Mr. James Gillespie, Mr. W. Stewart Morton, and others took part.

The lecture was illustrated by 10 lantern slides of English, French, and Italian cathedrals, and English abbey and parish churches.

Name and Address Required.

Will the correspondent who addresses us an enquiry from Leeds, signing himself "Brandon Grove," please forward his full name and address, without which we cannot undertake to answer his question?

A Costly City Hall.

One million seven hundred thousand pounds is to be the cost of the new City Hall and grounds in San Francisco. The building of this new hall, which will be of extraordinary magnificence, is to be begun at once upon the site of the old hall destroyed by the earthquake. The hall itself will cost £800,000, and another £900,000 is to be expended in the purchase of land in the neighbourhood.

DETAIL OF COLONNADE, OLD TOWN HALL, MANCHESTER.

THE LONDON OPERA HOUSE, KINGSWAY. BERTIE CREWE, ARCHITECT.

THE LONDON OPERA HOUSE.

Occupying one of the most prominent sites in London, the new Opera House in Kingsway has a main frontage of 265 ft., the Portugal Street side extending to 103 ft., while that in Sardinia Street is 108 ft.; the whole area covered being 4,500 ft. super. Portland stone on a granite base is employed for the main frontage, and is continued partly round each of the returns, which are finished in light red brick, with stone bands.

The entrance hall, which is approached by a broad flight of marble and mosaic steps, is embellished with columns and ainscot panelling, and has a coffered ceiling, executed in fibrous plaster; the ainscot being of mahogany. This hall opens on to the private-box foyer; twelve of the twenty-one boxes on this tier being provided with large ante-rooms. The stalls are reached by descending two marble staircases; and off the stalls there are sixteen more boxes.

Heavy girders carried on stanchions support the upper and lower tiers and the circle, and the box floor is suspended from the circle girder and from two wing girders carried from the circle girder into the stalls on each side of the auditorium; the view of the stage from all parts is unobstructed. The stalls and tiers accommodate more than 2,000 persons.

Details of the proscenium, etc., are as follows: Stage, 84 ft. wide, 64 ft. deep; proscenium opening, 45 ft. wide, 50 ft. high; top lights to stage, eight battens, containing 200 lights in each; side-lights, 75 at each side of the proscenium, with 12 hanging lengths of 24 lights each at sides of stage, all the lights being operated from one switchboard on the prompt side. A roof-garden is available for the use of the performers.

The statuary, by Mr. Thomas Rudge, comprises two chief groups, one at each end of the façade, representing respectively "Harmony" and "Melody," the central figure of each group being about 14 ft. high. The other figures symbolise Comedy, Tragedy, Song, and Dance, with two central figures (seated) of Inspiration and Composition.

Mr. Bertie Crewe was the architect, and the general contractors were Messrs. The Building Construction Company, Cockspur Street, S.W. The plasterwork shown by the accompanying illustrations was executed by Messrs. John Tanner and Son, of 6A, Grosvenor Road, S.W., and Liverpool. Other sub-contractors were the following:—Stonework, Messrs. The Bath Stone Firms, Ltd.; granite work Messrs. A. and F. Manuelle; marblework, Messrs. J. Whitehead and Sons, Ltd.; electric-light fittings, Messrs. Veritys, Ltd.; heating and ventilation, Messrs.

Strode and Co.; lifts, Messrs. Medway's Safety Lift Co. and Messrs. Hammond and Champness, Ltd.; rolling shutters, Messrs. Arthur L. Gibson and Co.; partitions, Messrs. A. and S. Wheeler; decorations, Messrs. A. R. Dean, Ltd.

THE NEW TUNNEL UNDER THE THAMES.

The new tunnel under the Thames, connecting North and South Woolwich, is now nearly completed, and will be ready for traffic during the summer. The cost was estimated at £78,860, and it is understood that that figure has not been materially exceeded. The L.C.C. has already carried out three tunnels of a similar character. They are:—Blackwall, £1,500,000; Greenwich, £180,000; Rotherhithe, £1,000,000. The tunnel extends from Nile Street, on the south side of the river, to Stanley Road, on the north side, and it has been constructed immediately near the spot where the ferry plies from bank to bank. It is 1,655 ft. in length, the inside diameter being 11 ft. 9 in., with a floor 8 ft. 9 in. wide. Entrance to the tunnel is afforded by means of vertical shafts, one at each end, built with the aid of compressed air

Entrance Hall.

Grand Foyer.

to a depth of 63 ft., on the north and 51 ft. on the south side of the river. Two spiral staircases, one for access and the other for egress, are erected in each shaft, and there is sufficient space for the provision of small lifts. The tunnel is level for 130 ft., with slight gradients on each side.

The work was designed by Mr. Maurice Fitzmaurice, the engineer-in-chief to the L.C.C.

COMPETITIONS.

North-Western Polytechnic.

In this competition, in which seven architects had been invited to submit designs, Mr. Arnold Mitchell, F.R.I.B.A. has received the award of the assessor (Mr. W. Flockhart, F.R.I.B.A.).

Spennymoor Public Hall.

The awards in this competition have been announced as follows: (1) Mr. G. T. Wellburn, Middlesbrough; (2) Messrs. Clark and Moscrop, Darlington; (3) Mr. A. Farndale, Brotton, Yorks.

Proposed New City Hall, Newcastle.

The committee authorised to report on the subject of the proposed city hall for Newcastle have recommended the site now occupied by the Northumberland Baths. They estimate the cost of building and equipment at about £100,000, and suggest that designs based on that sum shall be invited, and premiums of £500 (merging), £250, and £125 be offered.

Nurses' Home, Bolton.

In the competition for the new nurses' home which it is proposed to erect at the Bolton Infirmary as a memorial to King Edward VII., the assessor, Mr. J. B. Gass, F.R.I.B.A. has made the following awards: (1) Messrs. Henderson and Brown; (2) Messrs. Marshall, Robinson,

Son, and Wheeler; (3) Messrs. T. E. Smith and Son, all of Bolton. The Memorial Committee have decided to accept the design of Messrs. Henderson and Brown.

A Town Plan for Huddersfield.

Mr. W. P. Raynor, chairman of the Huddersfield Liberal Association, has written a letter to Mr. Alderman C. Smith, chairman of the Housing and Town-planning Committee of the Corporation, in which he says that on behalf of himself and a few friends he is enabled to forward £100 with the view of providing

premiums for the best scheme or plan of town planning and housing applicable to the needs of Huddersfield.

SOCIETIES AND INSTITUTIONS.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

A general meeting of this society was held on February 22nd, the president, Mr. Sydney D. Kitson, in the chair, when the feature of the evening was an exhibition of drawings from the Liverpool School of Architecture, Professor C. H. Reilly, M.A., A.R.I.B.A., giving an informal lecture on the methods of the school.

The large number of students and members present indicated the considerable interest taken in their work, and the debate which followed the lecture concluded a very interesting and successful meeting.

LONDON ASSOCIATION OF MASTER DECORATORS.

A meeting of the General Committee of the Association was held at 92, Queen Victoria Street, on February 12th, Mr. C. E. Wilkinson in the chair.

The Committee proceeded to the consideration of the publication of the revised report of the Education Committee, in conjunction with letters from the L.C.C. appointing a date for receiving a deputation.

The Chairman suggested that the whole of the Education Committee should form a deputation, with certain other members who had taken an interest in the subject, and this was agreed to.

It was agreed to make the Insurance Act a special item on the agenda in order to elicit the feeling of members at the next general meeting.

The Committee then proceeded to consider the desirability of urging local bodies as a means of relieving distress and meeting trade conditions to arrange their painting and decorating contracts at

THE LONDON OPERA HOUSE: STALLS FOYER.

THE LONDON OPERA HOUSE: DETAIL OF PLASTERWORK AROUND DOORWAY.

times when business was slack and in consequence much unemployment existed. After prolonged discussion it was agreed that the members of the Association and the trade should be invited to offer general suggestions on the subject.

The Committee next considered the subject of adopting a discharge certificate in connection with the trade. The idea was a certificate which the workman could carry containing particulars of his various employments, the length of time such employment was held, etc.

The Chairman said he would make a note to obtain samples and estimates of the proposed books in accordance with the suggestions that had been offered, and submit them to the next committee.

It was agreed that the general meeting should be held on March 25th, and that the following items should appear on the agenda: (1) action to be taken with reference to the Insurance Act; (2) report of the educational committee and the deputation to the L.C.C.; (3) to discuss the issue of certificates of employment and discharge.

GLASGOW TECHNICAL COLLEGE ARCHITECTURAL CRAFTSMEN'S SOCIETY.

At a meeting of this society on February 23rd, Mr. James S. Boyd presiding, Mr. James Muir lectured on "The Management of Building Contracts." The lecturer urged that a business and an architectural training was absolutely necessary to the contractor who was entrusted with difficult and costly work. Thus he would be enabled to give satisfaction to his clients and earn profit for himself. The lecturer also dealt with the terms laid down in schedules, the pricing of quantities, adjustment of claims for extras, etc., and insisted that no contract of any kind gave satisfaction unless the utmost harmony was maintained between the contractors and those who superintend the works.—T. DAVIS, joint secretary.

JUNIOR INSTITUTION OF ENGINEERS.

The annual dinner of the above Institution was held at the Hotel Cecil on February 17th. The president of the Institution, Commendatore P. Marconi, D.Sc., LL.D., was in the chair, and amongst the other guests were Vice-Admiral Sir H. B. Jackson (commanding the Royal Naval War College), Engineer Vice-Admiral Sir Henry J. Oram, Sir George Greenhill, Mr. G. C. Horsley (president of the Architectural Association), Professor John Perry, Count Albiz (managing director of the Spanish Marconi Company), Mr. G. C. Isaacs (managing director of Marconi's Wireless Telegraph Co., Ltd.), Major H. B. Strange, Professor H. J. Spooner, Mr. W. B. Bryan (engineer to the Metropolitan Water Board), and Mr. T. E. Gatehouse.

The toast of the evening was "Electrical Intercommunication," submitted by Professor John Perry, who, in the course of his remarks, said that in a very short time, he was told, they would be able to telephone from New York to San Francisco, and from London to any part of the British Isles. It is interesting to note that in the United States there were 6,000,000 telephones in use.

The President, in responding to the toast, spoke of the past, present, and future of wireless telegraphy.

An interesting feature of the evening was the presentation to Mr. Walter T. Dunn of an illuminated address, and a

cheque, in recognition of his services as secretary for twenty-seven years.

The other toasts were "The Junior Institution of Engineers," proposed by Mr. Gerald C. Horsley, Mr. Dunn responding; and "The President," proposed by Mr. S. Bylander.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

The annual general meeting of the above institution took place at the offices, Koh-i-Noor House, Kingsway, W.C., on February 27th, Mr. Howard W. Trollope in the chair, when the report and balance sheet for the past year were submitted. The latter showed that the income from subscriptions, donations, dividends, etc., was about £780, and of this amount the sum of £758 was paid in annual pensions, and also £5 granted as temporary relief.

The late Mr. John Howard Colls left to the Institution £270, which was allocated to the purchase of a presentation to the Orphanage Working School.

Mr. Howard Trollope was heartily thanked for his excellent services during the past year, and Mr. Dudley Bartlett, whom he inducted to the chair as successor, was enthusiastically welcomed.

The committee hopes to gain sufficient support to make the receipts cover the expenditure, and Mr. Dudley Bartlett is already working hard to achieve this.—JOHN AUSTIN, secretary, 39, Lordship Lane, Wood Green, N.

LONDON'S GUILDHALL BUILDINGS.

The City Lands Committee of the City of London have been authorised to print details of the scheme which for some time they have had under consideration for making extensive alterations in the Guildhall buildings. The proposal is to reconstruct the Art Gallery and the whole of the eastern wing, starting from where the Library premises end, and including the site of the present Irish Chamber on the opposite side of Guildhall Buildings. According to the plans which have been prepared by the

City officials, a bridge will be thrown across the street known as Guildhall Buildings. There is also a proposal, to which, however, effect would be given at a later date, to rebuild the west side, the part that is at present occupied by the Guildhall Justice Room. While no official statement is at present available, the main objects for the change are the provision of better accommodation for the Courts, and additional space for the Art Gallery. The plans which have been prepared show that there will be available for the Art Gallery three rooms 70 ft long, and several smaller rooms for cabinet pictures.

The proposal is as yet only in the initial stages, though a model has been prepared to show clearly what would be its extent. It has been approved by several committees that have considered it, and from the fact that leave has been granted to have the details printed it may be assumed that it has also been passed by the City Lands Committee. In order, however, that effect should be given to it, it will have to be brought before the Court of Common Council, who alone have power to authorise it and to provide the necessary funds—about £60,000.

COMMITTEE OF INQUIRY AS TO BUILDINGS ON SMALL HOLDINGS.

The President of the Board of Agriculture and Fisheries has appointed a Departmental Committee: (1) to inquire and report as to the nature and character of the buildings which should be provided for use in connection with small agricultural holdings in England and Wales, regard being had: (a) to the convenience and requirements of the occupiers; (b) to considerations of economy, and also the possibility of the reduction of cost by the use of materials and methods of construction different from those ordinarily employed at present; (c) to the special agricultural and building conditions of the different parts of the country; and (d) to the various requirements of the Public Health Acts and any Orders or Regulations made thereunder. (2) To submit a series of plans and specifications likely to be of assistance to local authorities and landowners for the purpose. The committee is constituted as follows: Mr. Christopher Turnor (chairman); Mr. Colin Campbell; Mr. E. J. Cheney, an assistant secretary to the Board of Agriculture and Fisheries; Mr. F. R. Harding-Newman; Mr. Cecil Harmsworth, M.P.; Mr. A. Ainsworth Hunt, M.S.A.; Mr. H. H. Law, M.Inst.C.E., Deputy Chief Engineering Inspector of the Local Government Board; Mr. Henry T. Tate; Mr. Raymond Unwin. Mr. C. W. Sabin, of the Board of Agriculture and Fisheries, will act as Secretary.

THE NEW A.A. SECRETARY.

At the last meeting of the Architectural Association the appointment was announced of Mr. F. R. Yerbury to the secretaryship rendered vacant by the death of Mr. D. G. Driver. Mr. Yerbury has been connected with the Association for the past eleven years, during which time he very ably discharged the duties of assistant to the late Mr. Driver. It is obvious, therefore, that no one with a more intimate knowledge of the Association and its work could have been chosen for the post; and the appointment is one upon which both Mr. Yerbury and the Association may be heartily congratulated.

MR. F. R. YERBURY
(Secretary of the Architectural Association).

HOPES AND FEARS FOR ARCHITECTURE.*

BY F. C. EDEN.

If, in Mr. Eden's paper, it is perhaps observable that the fears are more insistent than the hopes, it may be consoling to remember that the same criticism could be as justly applied to William Morris's "Hopes and Fears for Art," and that, indeed, this tendency is a common note of the critical temperament. The author's main contention seems to be that while fashions and fads may incessantly come and go, what is truly abiding is based on knowledge of the past.

EARLY in the century the Greek revival which had been suggested by Stuart and Revett's great work, and vivified by the importation of the Elgin marbles, attracted, to its rather dreary refinements such men as Inwood, Smirke, Elmes, and Lockerell, to be presently thrust aside by the careful, if uninspired, Italian manner which we associate with the name of Barry. Meanwhile, a more remarkable movement was gaining strength—namely, the Gothic revival, with Pugin for hierophant and Ruskin for its prophet. Though these enthusiasts deemed its foundations to be upon the holy hills of truth, eternal and immutable, the Gothic phase proved to be as temporary as any edifice raised with hands. Weakened by the strain put upon it by such essays in the ungainly S. Eaton Hall and Keble College, the rushing weight of Street's Law Courts brought about the slow collapse of the movement, and Bodley was truly the last, as well as the most cultured, of the Gothos.

Workman becomes Craftsman.

The reaction against mediæval copyism, which was intended for such, set in with some violence; fretful versions of "Queen Anne," free (and easy) or ungrammatical classic; Dutch and Flemish motives all ad their little day. Soon we began to hear the workman whispered of as a craftsman. The professional architect became the bugbear of some. The craftsman then it was who was to redeem the arts; though how he was to do so without his ancient backing of tradition and hereditary skill is not even yet apparent. A small vogue, hardly to be called a fashion, was once started in favour of the Byzantine manner by a building not far from here, but I do not fancy it ever came to much.

Picturesqueness and a Classic Impulse

All this time the grand manner of domestic building had been forgotten; picturesqueness was everywhere attempted, and misunderstood to consist of jagged skylines and jumbled incompatibles. In the next stage the hidden stirring of some Classic impulse moved the professors of this nook-and-corner style to prune, chasten, and square up their designs. Sobriety began to rule.

We are not altogether surprised to notice how large a proportion of the designs submitted in recent competitions are rather bleak and toneless efforts in the sort of Greek that is learnt by looking over a Frenchman's shoulder. Whatever excellences they may possess in planning and so forth, it must be admitted that they leave us cold. But of all fashions in art, Paris fashions are now for us the most pernicious. Just as in literature each language has its individual genius and rhythm, so in art. Gallic idioms are of ours, Gallic graces quite other. Consider the influence of French ideas upon the current manner of design as displayed in recent buildings and competitions. I do not know how to describe it except as a kind of architectural cubism. The dominant motif is the block. We watch

it standing uneasily on cornices, hanging from sills, stepped, imposed, superimposed *appliqué* to the wall face; tight wreaths of laurel and myrtle clasp and interpenetrate it; guttae weep from it—there is no designing without tears now for the young architect—while scraps of columns, mouldings, or carving emerge with Rodin-esque inconsequence from ponderous chunks of masoned stone.

Fashions and Art.

Are we to account for the incessant change which the last hundred years have witnessed as a stirring of vigorous life or as a restless craving for some new thing? Seeing that all great accomplishment in the past has come from working steadily along a simple line of age-long tradition, it cannot be seriously maintained that such rapidly changing fashions are beneficial to art. Nevertheless, almost every passing phase has left some good behind it.

The Gist of the Gothic Revival.

For example, there is still something to be learnt from the Gothic revival. The lesson is, I think, twofold. First, enthusiasm. The writings of Pugin, Street, and others brim over with it. Such books as "Brick and Marble in Italy," or Webb's "Continental Ecclesiology," are most refreshing reading for this very reason. However much we may smile at some of its manifestations of zeal, we may well sigh for a share of that contagious spirit. And, secondly, definite principles, without which enthusiasm runs to seed. The chief apostles of the movement—Pugin, Morris, and pre-eminently Ruskin—made an earnest attempt to decipher and codify the laws of artistic conduct. If the principles enunciated by these "intolerant amateurs" were universal and sound, I am not concerned to deny that a certain falseness and partiality in their application has run back like a taint and corrupted the source; with the result that now there is little recognition of any fixed laws or æsthetic standard. The followers of art have become an undisciplined mob with a mob's capricious temper, and the practice of art has become a riot of eclecticism and experiment.

Again, it was the arts and crafts movement which emphasised the importance of a more intimate relationship between material, workmanship, and design; and though the doctrine is sometimes pushed to the point of absurdity, its influence has already been considerable and in the main wholesome.

The Craze for Antiquity.

The present is an age of connoisseurship. Old panelling, chimneypieces, and other fixtures are fitted up in new homes. Dilapidated vases, figures, sundials, and worn-out paving-stones grace freshly laid-out gardens and terraces. Pavements are laid and walls built to give hold to vegetable growths, and sprayed to encourage lichen and mosses symptomatic of hoary antiquity. Oak is greyed with lime and sandblasted to give it texture, marble is stained, gilding and paint are toned and glazed to obtain the effect of age. The same effect is sought by

reversion to materials and methods that were used of old time. The materials selected are such as weather well and soon lose their rawness and novelty. Bricks are rough and small, joints are wide and white, and pointing is eschewed; timber is wrought with the adze and peppered with protruding pins; stone is roughly tooled and so left; wall-plastering is finished with an undulating surface; roofs are laid in gently sweeping curves and of second-hand tiles, if such are to be got.

Some may be inclined to divide these methods of treatment into legitimate and otherwise. The use of the adze, for example, though somewhat of an affected archaism, may be tolerated; while the sandblast is a fraud and a fake. The whole tendency will be condemned by others as unwholesome, decadent, and dilettante. But if the surface produced upon timber by the sandblast be artificial, is it one whit more so than that produced by the circular saw or the planing machine? And if greying with lime be illegitimate, what about yellowing with boiled oil? And, finally, if it be a fraud to make new buildings look old, how shall we characterise the really successful attempts of many architects to make old buildings look new?

Advancement of Taste.

The question of the education of the architect is ever with us, but what is really pressing is the education of the general public. However scholarly and efficient as a body architects may be, they are powerless until the outside world becomes interested and appreciative. However, there is little doubt that among educated people the knowledge of architecture has made enormous strides during the past thirty years, and I think that for this advance connoisseurship or the collecting mania is largely responsible. It does breed in its victims a feeling for form, an appreciation of good workmanship, and it creates a standard. In other words, it educates popular taste. It would seem to be partly the cause and partly the effect of the present popularity of eighteenth-century art, which is, at first sight, so strange and unaccountable.

Art and Contemporary Life.

What is there in its refinement, repose, and freedom from advertisement, its coldness and aloofness and well-bred restraint to appeal to a bustling and commercial age? For art does not go by contraries. It is an expression of contemporary life. The haphazard, unrelated, and individualistic dwellings of the Victorian era, for example, reflect clearly enough the industrial expansion of the time and consequent emergence of the middle classes. They are eloquent of newly fledged and inarticulate ambitions, of that self-assertiveness and carelessness of treading on another's toes so characteristic of the race of men who have started in life with the proverbial shilling.

The author of a recent article on "The Aristocratic Influence in Art" notes with surprise that this cult of Georgian art is "accompanied by no sign of interest in the human significance of the style. It never seems to be imagined by its votaries that eighteenth-century art, coherent and consistent as it is in all its details, stands for a certain definite philosophy of life. Not a trace does it exhibit of the superabundant vitality and warmth of popular art, but rather inclines to a certain coldness and arrogance of expression, its very perfection of taste lending it an air

of exclusiveness, as a thing aloof from common appreciation. It is its aristocratic purpose or tendency which constitutes its note as a style, and is an accurate reflection of the aristocratic ascendancy which began with the overthrow of the autocracy of the Monarch in 1688, and lasted until the Reform Bill. The author goes on to suggest that the coming democratic ascendancy will be registered in art in the same way, and concludes that "the air is full of promise. Beneath modern connoisseurship, itself the inevitable legacy of the aristocratic epoch, a healthier and stronger movement is fermenting. It is from the workshops of England that the rescuers of our art are coming. In the modern democratic advance lies the best hope for art." This reads like an echo of the old arts and crafts war-cry, but there is room for serious doubt whether great art can be born or thrive under a democracy. Athens was to all intents and purposes an oligarchy, so was Venice. What has Switzerland done for art? And she alone among democratic States has had time to show her capabilities. Still, if there be ground for this hope, if the democratic advance be reddening the horizon, surely our public architecture should catch some reflection of the coming dawn.

Vernacular Architecture.

But of this I am convinced, that we have a form of architecture which is pure vernacular, racy of the soil, straight from the "great heart of the people." It is built with entire and obvious singleness of aim, without affectation or conscious striving after beauty, and of the materials that are easiest to be got. The professional architect, that boggy of a certain school of critics, has no part nor lot in it. It comes as direct from the workshop as anything possibly could do. I allude to the architecture of the typical suburb, of the artizans' quarter, of the speculator. Perhaps this is where the true hope for architecture lies. Who can tell?

Reinforced Concrete.

The main purpose of all mechanical inventions, from the printing press onwards, has been not that things may be better done, but that they may be more quickly done. This, I suppose, is the chief recommendation of reinforced concrete as a building material.

Attempts have been made abroad if not at home to originate a style peculiar to a new and untried material. We are to use it in the most direct way possible, with entire truth to its qualities of thinness, toughness, and so forth. A monolithic building should achieve such expression as it is capable of without imitation of other materials or reminiscence of other methods of construction. Let it confess itself for what it is without concealment and without shame. This is the way, we are told, to achieve character; beauty may come later—out of the strong will come forth sweetness. But whatever the material we are using the natural conditions of gravity, weather, and light remain unchanged; and our endeavours to meet these conditions cannot be expressed in ways wholly different from those of the past.

Treatment of Wall-face.

Some, again, are sorely puzzled over the proper treatment of the wall-face. One will employ acid to dissolve the matrix and expose the aggregate, another will tap the surface to remove the aggregate and emphasise the matrix. A third, following a counsel of despair, cloaks his

skeleton with stone, brick, or faience, which does not seem a great advance upon the Tower Bridge type.

To the man whose tastes are calculating and scientific reinforced concrete makes an irresistible appeal; whereas, in the view of the *laudator temporis acti*, an ounce of tradition, that is to say, experience methodised by the knowledge that comes with centuries of practice, will always outweigh a ton of professional theorising. Though, I dare say, he will be glad enough to use it on occasion, however shamefacedly, to help a lame dog over a stile or cut some Gordian knot of construction.

The Shop Front.

Just as the church and the castle may be taken as typical mediæval aspirations, so we may safely select as the building most representative of the spirit of this industrial age the shop-front. It has been dinned into us from our architectural cradles as a prime axiom of criticism that every edifice must be expressive of its purpose and use. What the requirements of an up-to-date shop may be an up-to-date shopkeeper may be trusted to know. In the din and rattle of commercial activity it is doubtless necessary to yell like a virago on a doorstep in order to be heard; and so the shopman declares for the largest possible area of glass for the advertisement of his wares; and threatens the building owner with an appreciably lowered rental for every post and pier beyond the engineer's minimum.

What, then, is to happen when the conditions imposed are vulgar, sordid, or unworthy? Simply this: if the axiom above stated is to hold good, the architecture will have to follow suit; and then the strangest result ensues. To save his art from shipwreck the skilled architect throws overboard its first principles, and his design becomes an inexpressive or lying mask. But such conditions do not hamper the careless practitioner. He complies with them willingly enough, and so his work is actually more characteristic and expressive than that of his conscientious brother.

The Block of Flats.

Or we may consider another class of building common enough in large towns—the block of flats, or the oddly named "model dwellings." Here conditions which imply several storeys of approximately equal height, subdivided into suites of small rooms, produce of necessity frontages in which the proportion of solids to voids is much the same as in a sieve. Add to this the necessity of building cheaply enough to show a fair percentage upon capital invested, and I ask you whether architecture so conditioned can be monumental.

A Rosier View.

But it is possible to take a rosier view. "The true artist," it is said, "unhesitatingly accepts the conditions imposed upon him, whatever they may be, and is often able to turn the stumbling-block in his path into a stepping-stone to higher things." It was in this spirit that a lecturer not long since twitted architects with overmuch clinging to the past. He maintained with spirit that architecture must be living, and in order to live must find its poetry in the life and its inspiration in the opportunities of the present; and surely never were opportunities so many, so splendid, or so various as now. To make his meaning clear he was obliging enough to enumerate some of the occasions upon which the divine *afflatus* may be trusted to inspire the erection of poems in (I suppose) reinforced concrete.

Are we not building every day, he cried, hotels, railway-stations, asylums, baths and washhouses, and abattoirs?

What of Town Planning?

And now what of town planning? Is the movement which has by this time gained considerable momentum likely to communicate any forward impetus to your art? The cottage heresy is indicative of a sickness which has long afflicted British architecture, and that is pettiness. By this I mean not only the material malady, timidity of scale—so noticeable in our larger buildings—but the more serious spiritual disorder, smallness of idea. Have we any ground for hope, based on the experiments at Port Sunlight, Letchworth, Golder's Green, and Gidea Park, that when the designer has to think in acres instead of poles and in streets and squares instead of single houses, his ideas will be braced to a large scope, or will they peter out in a mere multiplication of diminutive and unrelated units?

Modern notions of hygiene and traffic facilities incline to the spacious boulevard—icy and wind-swept in winter, dusty and scorching in summer, and wide enough to enable the greatest possible number of steam-lorries to rattle your windows and jar your nerves in the shortest possible time. But where, I ask, is the lover of good things wont to linger in his search for beauty and historic interest? Among the straight, unhaunted streets of Mannheim, Karlsruhe, and Turin, or among the memories and surprises of Toledo, Siena, and Bruges? And as to what constitutes the ideal town, some of us may be inclined to think that the opinions of the painter and the poet are at least as valuable as those of the inspector of nuisances and the sewage farmer.

Knowledge of the Past.

When all deductions have been made for the evils to which architecture has to submit in allowing the dictates of fashion or in compliance with requirements of ever-increasing complexity and uselessness, we may, I think, claim to have made real progress in one, and that a most important, particular, since it covers nearly the whole ground—namely, sympathetic and, as far as possible, traditional treatment of material, involving as it does both texture and colour. We have realised that architectural, like other beauty, is only skin-deep.

Improvements in taste and feeling have been brought to pass not by the invention of new materials and methods, but by increased knowledge of the past. The further we are enabled to enter into that rich heritage, the clearer will it become to us that "in its contact with the ages the wisdom of the ancients has come down to us absolutely unimpaired."

DISCUSSION.

Mr. Edward Warren, proposing a vote of thanks, said that Mr. Eden had been most entertaining and suggestive, but destructive rather than constructive. His fears had predominated over his hopes. The dismal failure of the early nineteenth-century Greek phase, he continued, had been prepared for by the thin refinements of the late eighteenth-century and the emasculated Adam manner. There had lately been a recrudescence of Greek ideals; but he trusted it would not last very long. The Gothic Revival, of course, was begotten of the romantic writers—Horace Walpole, Sir Walter Scott, and, later, Tennyson—rather than of architects. He would like to protest against

coupling of Keble College with Eaton all as "essays in the ungainly." Despite defects, the proportions of Keble College were fine; the chapel over was able in conception, and the work of a genius—though probably of a genius he was wrong. The Parkes Museum, with its high-pitched roof and variegated slates, is still more violently un-Oxonian. The Gothic devotees—Butterfield, Bodley, Sweet, and Pearson—all had considerable scholarship, and all were convinced of the quality of the Gothic renaissance. Newt, continued the speaker, was practically and; after a short dalliance with its gggly abominations, we had steadied down to a saner and, he thought, more indicated view of the meanings of architecture. There was at present a tendency among the weaker brethren to borrow from France—a dangerous practice if the fashions were not translated into English. The benefits of this borrowing were proportion and refinement. Men of long bent would express their personality in spite of it—genius could always take care of itself; but they had to consider the average man, the mildly contented, for whom the architectural look was difficult, if not obscured. The best constructive training and refined modeling in expression, he thought, would help the architectural student to avoid the many pitfalls presented by the facilities of modern methods, the steel and reinforced-concrete aids to constructive disabilities. He was not pessimistic; he believed there was hope, and, though hope, in the steadily growing consensus of architectural opinion. That Hampstead Garden suburb was exerting influence upon its surroundings, was a parent from the better class of house; it was springing up in the immediate neighbourhood.

Mr. H. H. Statham, seconding the speaker of thanks, said that the paper was a difficult one to comment upon. With regard to Street's Law Courts, the speaker was not in the detail or the style, but in defective planning. The Great Hall, intended as a *salle des pas perdus*, was put on a wrong level and was always empty. He had to dissent from Mr. Street's statement that architectural beauty was only skin-deep. He (the speaker) thought that architectural beauty was out of the plan. Ruskin's "Seven Upstarts," of course, was full of propositions which would not bear examination; and he would not advise anyone to take all its things as gospel. With respect to modern methods of building, they could expect to get good architecture and good building done in a hurry. He remembered an American architect saying that in his country complete drawings were frequently wanted within a week; an architect protested against the time the client would say he would go where where he could get them in time. It appeared to him (the speaker) that this would account for the prevalence of the Classic style in America, its main features being more or less photostyped and ready for use. The speaker, he thought, was beginning to doubt that the architectural shop would survive in the long run. The shopkeepers protested against Mr. Norman Shaw's shops in the Regent Street quadrant, but, when the shops were now occupied, it did not seem that they had overcome their objections to the architectural shop. Referring to domestic architecture, Mr. Statham said there was no longer nowadays to build high-pitched roofs. He would like to see a garden city with

flat roofs; for this was really the most practical method of roofing. Windows, also, were usually much too small for hygienic conditions.

Mr. Arthur Keen said that Mr. Eden had not done full justice to the Gothic Revival. The Gothic Revival was not Gothic at all; but work was produced which possessed the qualities of really fine architecture. This was especially the case in church work, such as St. Alban's, Holborn, and St. Matthias, Stoke Newington. The Gothic Revival, he could not help thinking, was a mistake, for it left men who forged not only architectural design but craftsmanship also. Such work could not be sufficiently strongly deprecated. The present Georgian revival, he thought, was justified, because it was enjoyed and appreciated by the people. It seemed to him that architectural unsettlement was inevitable. We should never settle down, for any length of time, to what could be called a national style. Things now moved more rapidly than before, and the arts would

have to fall into line with the spirit of the age. He thought that before long Socialistic principles would obtain generally, and architecture would become officialised; it would therefore have to be developed on academic lines.

Mr. A. E. Richardson said the nineteenth century produced enormous commercial activity throughout the world, and a corresponding activity resulted in artistic circles. Mr. Eden spoke of a "Greek Revival," and also mentioned "mutterings of a second Greek Revival"; these statements in particular needed explanation and correction. The development of English Classic architecture properly commenced with the building of the Banqueting Hall by Inigo Jones; thence it was continued by Sir Christopher Wren and other architects until the first quarter of the eighteenth century. From 1730 the Palladian character of the vernacular style was blended with a more precise knowledge of Roman architecture. Following this came the researches of the Dilettante Society and the publication

N^{os} 121 & 122 FLEET STREET, LONDON.E.C.

Gate to Common Entrance Passage from Fleet Street.

This gate is, we believe, to be demolished shortly. Though of quite simple character, it is sufficiently interesting to be worthy of record.

of Stuart and Revett's great work. This occasioned the Græco-Roman phase, which, in turn, during the first quarter of the nineteenth century, developed into a purer Greek manner. The giants of the nineteenth century—Cockerell, Elmes, Barry, and Pennethorne—initiated a modern Classic development. They fused the preceding phases of English Classic with Italian and French *motifs*, and brought about the Neo-Grec and Italian culmination. In this connection practically the last building in the monumental manner to be erected in the United Kingdom was the Harris Library at Preston, completed in 1896. Thus the earlier Classic of Inigo Jones and Sir Christopher Wren, nourished by the researches of Englishmen in Greece and Rome, had continued for nearly three hundred years. Therefore, it was fallacious to speak of "revival." The fact that the practice of Classic architecture had been continued so long in this country was sufficient proof of its being the best medium for modern academic expression. The hope of modern architecture lay in the furtherance of a cosmopolitan style; insular prejudices had to be forgotten and a broader view taken of the changed conditions of life. If Sir Christopher Wren had not availed himself of the opportunity of peeping over the shoulder of "that crafty old Italian fox" Bernini, it was possible we should not have had such a fine building as St. Paul's Cathedral.

Mr. V. T. Hodgson said he thought Mr. Eden was hopeful. His hope was in a Gothic revival.

Mr. Alan Potter said that if he had one thing greater than fear for modern architecture, it was hope for the future. The chief trouble was that we knew too much about the past, and thought too much about the present. Military education required the study of military history, not for its ancient tactics, but for the development of new ways of getting out of modern difficulties. Architecture should be studied in the same way. People of the thirteenth century did not study Saxon work; they studied the very latest work, and tried to improve upon it. We too had got to study modern work if we were to overcome the problems of our day.

Mr. C. C. Brewer said that the modern competition system was producing a body of fine planners, and therein he saw a hope for the future. We had given up thinking of elevations and thought only of plans.

Mr. Curtis Green said he had long recognised Mr. Eden as one of the few men we have ahead of their time. The paper, he continued, separated the artist from the Philistine without the latter being aware of it. It was a paper full of golden silences; the reticences of the good craftsman. If he were right, Mr. Eden regarded any recent improvement in our architecture as due to our increased knowledge and respect for the past. He detected in Mr. Eden's view three hopes for the future: (1) Tradition; (2) enthusiasm; and (3) definite principles.

Mr. F. C. Eden, in reply, said he was not so pessimistic as he apparently was thought to be. With respect to Keble College, he had spent four years there, and he still thought that, with the exception of its proportions, it was all wrong. Mr. Eden then drew a comparison between a building and the human form in support of his contention that architectural beauty was only skin-deep.

NOTES ON PAINTING AND DECORATION.

BY ARTHUR SEYMOUR JENNINGS.

Experiments in Proposed Substitutes for Linseed Oil.

Some very interesting and practical tests of paints are being made by the Institute of Industrial Research, Washington, D.C., in conjunction with the American Society for Testing Materials. This Institute issues from time to time bulletins or pamphlets containing a record of results obtained by exposure tests. One just received deals with practical testing of drying and semi-drying paint oils, the tests being undertaken in consequence of the long-continued high price of linseed oil. Forty-eight white pine panels were painted with a standard white pigment formula reduced with a different oil formula for every panel. Each panel was constructed of four tongued and grooved planed boards 22 in. long, 1 in. thick, and 9 in. wide. They were painted before being fitted in position during the month of April, when the temperature varied from 60 to 90° F., and the paint was allowed to become thoroughly dry before the various paint mixtures were applied. It is interesting to observe that the standard pigment selected was not pure white lead only, but a composite paint made up as follows:—Pure white lead (hydro-carbonate) 20 per cent., sublimed white lead 30 per cent., zinc oxide 35 per cent., magnesium silicate 10 per cent., barytes 5 per cent. The 100 lb. pigment base was ground to a stiff paste in 16 lb. of linseed oil. Various oils and mixtures of oil were then added to thin the paint to a state fit for application, the pigment being the same in all cases. Among the oils thus tested were raw linseed oil, soya bean oil, Medhaden oil—both the last two being mixed without linseed—mixtures of 25 per cent. of raw and 75 per cent. boiled linseed oil, and various other proportions; blown linseed oil, corn oil, cotton-seed oil, were also used. The report shows that the oils in drying increased in weight, and that the greatest increase in weight occurred during the period in which the oil dried to a firm film, which was in most cases within 48 hours.

Times of Drying of Various Oils.

Space will not permit of all the results being given here; but a few may be mentioned. Boiled linseed oil dried in two days. Blown linseed oil proved difficult of application owing to its thickness, and dried in less than two days to a smooth film; mineral oil at the end of the nineteenth day was found to have lost in weight on account of the presence of volatiles, and no drying action was observed. A mixture of 20 per cent. mineral oil with 80 per cent. raw linseed oil—the film remained tacky until the end of the eighth day, after that a fairly firm film was shown. Soya bean oil when used by itself was fairly firm after the fourth day, but when mixed with 80 per cent. of raw linseed oil it was firm at the end of the second day. Cotton-seed oil showed very little hardening, and the same is true of corn oil. Sunflower oil was fairly firm at the end of the third day. Medhaden oil and Chinese wood oil gave very fair results.

The same pamphlet contains a separate report on paints suitable for steel. Plates were painted in October, 1908, and have been exposed on the seashore since. On June 28th, 1911, they were examined, and ratings were given to each panel according to the amount of rust apparent

on the painted surfaces, as well as the degree of checking, chalking, scaling, cracking, peeling, loss of colour, and other signs of paint failures shown. Observations were made by four different experts and an analysis of averages showed chrome scarlet to give the best result, being placed at the top of the list. Next came chrome green of a blue tint, the zinc and lead chromate, zinc chromate, zinc and barium chromate, magnetite, black oxide, sublimed white lead, Prussian blue, etc. Venetian red had an average percentage of 8 per cent. as against 10 per cent. for the highest, sublimed white lead. Among the paints which proved to be utterly useless, or nearly so for painting steel, were calcium carbonate, whiting, ultramarine blue, and chrome resinate oil. Boiled linseed oil without pigment was used in three coats, and only gave the average of 1.5. Thus it is clearly shown that oil by itself is useless for protecting metal, and that soya bean and Medhaden oils may be employed in proportion of less than 25 per cent. with good linseed oil without the drying of the paint film being retarded.

The Smell of New Paint.

Freshly applied paint is always more or less objectionable, and ladies and others of delicate constitution sometimes suffer in health in consequence. The "Lancet" some years ago pointed out the danger to those persons who are sensitive to the vapours of paint, and what is the same thing, to the turpentine and oils contained in the paint, as advised those who are so affected to resign their home until the drying influences of the air had dissipated the volatile oil. There is possibly increased danger when white lead is used, from the lead emitted, although this has not yet been absolutely proved. A well-known scientist shows some time since, that he had by means of the spectroscope obtained traces of lead being thrown off from a newly painted surface. Whether this occurs in sufficient quantity to cause injury to health has not been determined. It is not so generally known as it might be that zinc paints such as zinc oxide and zinc sulphide when used as paint, do not possess the characteristic smell of lead paints. This should be so has not yet been made clear, but possibly the smaller amount of turpentine used to some extent explains it. As to the remedies, bowls of water—or, better still, of milk—are recommended by the "Lancet" as giving some assistance in the matter. These are exposed on the floor of a room which has just been painted, and they appear to absorb some of the fumes given off, and can be easily proved by the paint emulsions showing on the surface of the water so exposed. Fresh milk reduces the smell of paint in a room in a remarkable way. Juniper berries burnt in a room are said to assist in this matter, the fumes given off probably only disguise those of the paint. Fresh hay is also recommended, as well as oil of birch wood tar.

Paint Solvents.

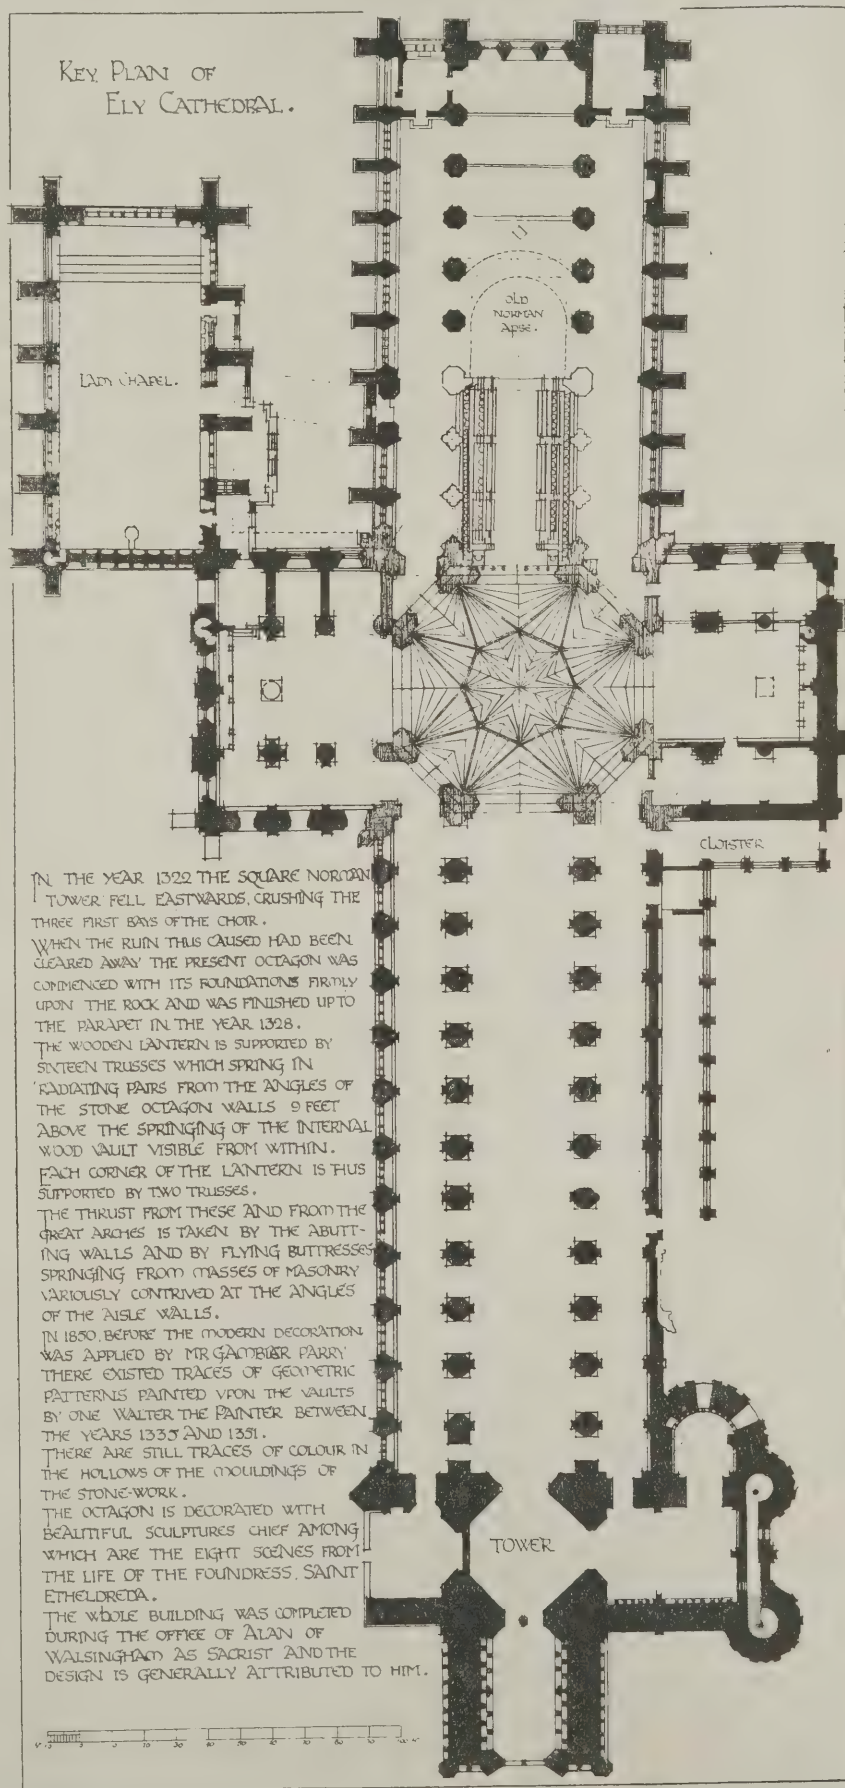

Judging from the many paragraphs that appear from time to time in the trade press, there seems a great deal of misunderstanding among builders and architects as to the best materials for removing paint or varnish. It is perhaps four or five years ago, paint

usually burnt off, or, rather, softened by heat and then scraped off, or was softened by the application of a material consisting of either soda or potash mixed with quicklime. The chief objection to the burning-off process is that it is likely to cause the sharp angles of the moulding, etc., to be charred. The fumes arising from the burning paint are very objectionable, particularly when inside work is being dealt with, while there is undoubtedly no little danger to the workman who is compelled to inhale the bad fumes. Various alkali softening mixtures which are still used to a considerable extent are likely to injure the hands and the brushes also; they tend to raise the grain of the wood, and this objection is increased with the use of water necessarily employed in washing off. However carefully this is done, there is still a certain amount of alkali left on the surface, so that in practice it is necessary to apply a coat of dilute acid, such as vinegar, before the new paint is applied. There are, however, literally dozens of paint solvents which are wholly free from the objections named. Several of these have been on the market for some years, and they consist for the most part of acetone, benzol, or benzine, and in some brands a hard wax, such as carnauba, permacet, or paraffin wax, is added in order to yield a paste which will hold and prevent too rapid evaporation. Paint solvents of this class do not injure the hands or brushes, but soften the paint or varnish in a very short time, and it may then be scraped off, and the surface rubbed clean by means of a piece of rag dipped in a little turpentine or benzine, when the work is ready for re-painting. Speaking generally, it will be found that burning off is economical for outside work, but that a paint solvent is best for work that is to be done inside.

adding to the site an additional area of 22,000 sq. ft.

That part of the work which had to be carried out in close proximity to the abutment of Westminster Bridge, built in 1862, presented a special problem. The abutment on the Lambeth side of that

bridge was originally founded on timber piles, but the depth to which the foundations for the new river wall were carried made it necessary to go below the bridge foundations. To avoid the risk of damage to the bridge it was decided that the abutment likely to be affected should

LONDON'S NEW COUNTY HALL.

The King, in laying the foundation-stone of the new London County Hall on March 9th, will initiate the final stages of the undertaking. Illustrated descriptions of the building have already appeared in the Journal, but at the present stage it will be interesting to recall a few salient particulars, which are reproduced from an article in the "Times," in which the engineering features of the work are detailed.

The total cost of the whole scheme in its original form, including the cost of land and buildings, a reclamation scheme on the river foreshore, the building of an embankment wall, and the erection of the hall, was estimated at £1,700,000. The plans have, however, been modified in certain details, with the result of reducing the total outlay.

The course of the Thames at this point being almost due north, and the site being parallel to the river, it was easy for the architect to provide façades with south, east, and west aspects, thus securing a maximum of sunlight for the council chamber, committee-rooms, and principal offices.

A great deal of preparatory work was required before the site was ready for the operations of the builder, it being necessary to enclose the area on the river frontage by an embankment wall 588 ft. long, and to reclaim from the foreshore of the Thames about two acres out of the five and a half acres included in the site. The line finally adopted for the embankment wall was a curved one, which had the effect of setting the wall forward, and

be entirely enclosed in steel sheet piling. As an additional precaution, a specially designed caisson, shaped to fit the pointed cutwater of the abutment, was sunk under compressed air and sealed with concrete, to form the foundation for the 47 ft. of the embankment wall next the bridge. This operation was successfully accomplished without causing any disturbance to the bridge abutment, and allowed the remainder of the work to be carried out by more normal methods.

After the construction of the cofferdam the building of the embankment wall was a comparatively simple task. About 800 ft. of wall would be required to enclose the whole side, but although only 588 ft. of wall has been actually constructed, provision has been made by the building of a temporary timber structure for the extension of the embankment. The river wall has been constructed in cement concrete faced with granite ashlar work, Aberdeen and Cornish granite being used for the ornamental parapet. A pleasing architectural feature of the new embankment is furnished by the centre

flights of steps. Behind the wall a series of arches has been constructed for storage purposes. Mr. E. H. Tabor acted as resident engineer for this work, for which Messrs. Price and Reeves were the contractors.

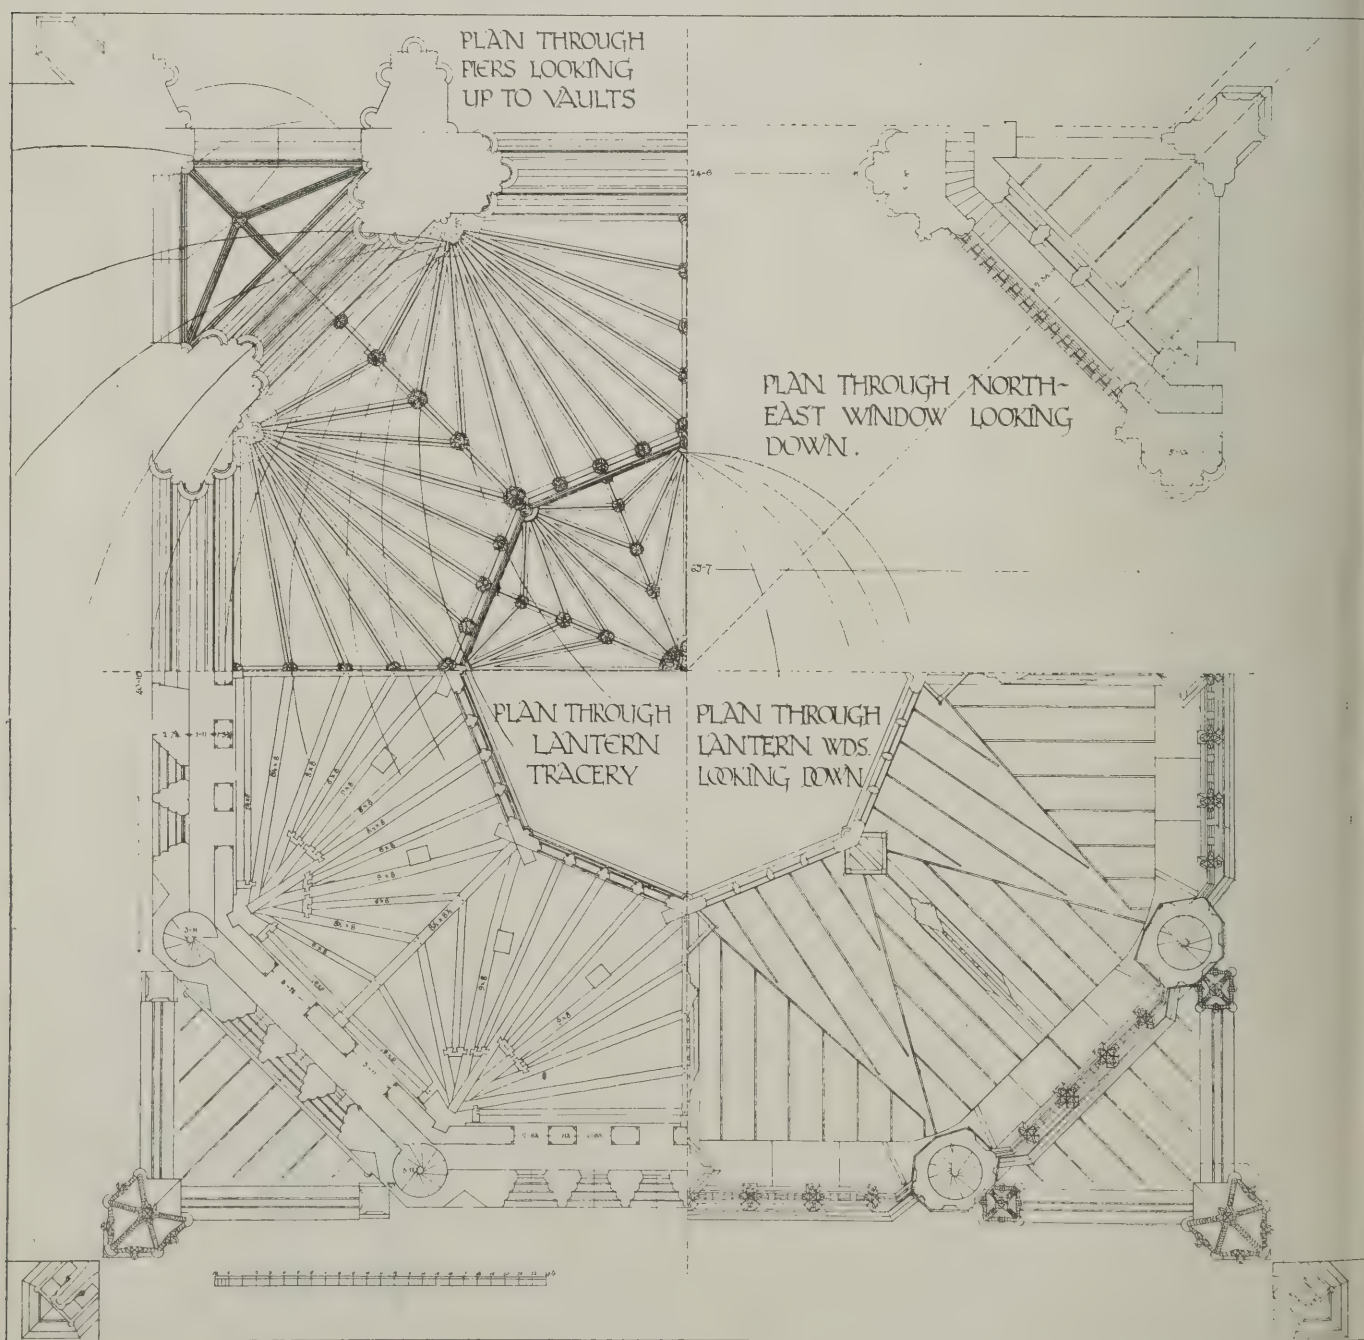

The preparation of the foundations for the hall went on simultaneously with the building of the embankment, a separate contract having been let to Messrs. F. and H. F. Higgs. The first work was that of demolishing the buildings which occupied a portion of the site. Preliminary boring operations showed that the strata included 12 ft. of made ground, 7 ft. of Thames mud, and 13 ft. of ballast lying over the London clay, and the plan adopted was to provide a Portland-cement concrete raft laid on top of the ballast formation. There were several advantages in this method, but it necessitated a good deal of excavation, and had the effect of placing the foundations considerably below the level of Belvedere Road. The engineering plans therefore included the provision on the unprotected south and east sides of the site of concrete retaining

walls with a base thickness of 10 in., tapering to 4 in. at the top. The embankment served the purpose of a retaining wall on the river side. On the watertight box thus built the new County Hall was erected.

The hall itself will be a building of nine storeys, 750 ft. long and about 320 ft. in width.

THE OCTAGON, ELY CATHEDRAL

The magnificent Octagon of Ely Cathedral is shown in this issue by some excellent measured drawings, which gain for Mr. A. B. Allen this year a certificate of honourable mention in the competition of the Royal Institute of British Architects. The perspective reproduction on page 238 and the section and elevation given as the Centre Plate in this issue, especially well done, being examples of accurate draughtsmanship combined with a sense of artistic effect. Particulars of the construction will be found on the plan published on the preceding page.

THE OCTAGON, ELY CATHEDRAL. MEASURED AND DRAWN BY A. B. ALLEN.

A CENTURY OF BUILDING.*

BY MAURICE B. ADAMS, F.R.I.B.A.

In a rapid review of the history of architectural developments from the reign of George IV. down to that of the present monarch, Mr. Maurice B. Adams recalls many interesting facts, and briefly summarises the careers of many outstanding personalities.

THE manners and morals of the age whence we are starting had degenerated, and times were not particularly brilliant in 1821, when the "First Gentleman in Europe" ascended the throne, so in order to take our bearings it is requisite to glance back even so far as Stuart days to adjust properly the antecedents of Early Victorian art. Evolution in design had spent itself by the time of George III. No tradition worth mentioning remained, and our most accomplished achievements henceforward were due to individual example. Academicalism had reigned long enough. "The Neo-Classic period," which has been divided thus, extended from 1666 to 1820: the Formative period, from 1666 to 1720; the Palladian period, from 1720 to 1760; and the Formal school, which ended in 1820.

The Great Fire.

War and fire have generally contributed to the advance of architecture, and since the era of the Middle Ages the one outstanding event which had the most immediate influence upon subsequent building art was the Great Fire of London in 1666. Wren thus was given his opportunity. The second conflagration to be mentioned as of architectural import was the burning of the old Houses of Parliament in 1834. These two events coupled in this way define the beginning and the end of the "Neo-Classicism" of English building.

The Gothic Revival.

Till the turn of the tide of fashion towards the closing years of the last century indigenous architecture became associated more or less with the "Gothic Revival." So little attention, indeed, was devoted fifty years ago to Classic work, that no one could have thought it probable that the praise of Soane and his school would find expression in the early days of the twentieth century. Belcher and Macartney's book on "The Later Renaissance" helped to bring about this swing of the pendulum. Long prior to the Georges, beauty, colour, and grace had succumbed to the Puritans, the Revolution, and the iron hand of Cromwell. Dress had become sober, the cut of its lines was formal, faces wore a hard expression, and, as materialism gained the ascendancy, enthusiasm had become associated with what was thought "bad form," and art was glacial. Houses were grey, with flat roofs and hopelessly dull interiors, although some of the better sort exhibited a somewhat architecturally contrived plan, recognising vistas by making one room lead out of the other.

The "English Style."

A reaction so early as the dawn of the nineteenth century evinced signs of activity; but so little was mediæval art comprehended that it was generally spoken of as "the English style," ignoring the historic art of Europe. Wyatt was building Fonthill Abbey, known as "Beck-

ford's Folly," on an enormous scale, with puerile and petty detail; but an advance was registered when John Shaw erected the clever church of St. Dunstan-in-the-West in Fleet Street, and added a respectable deception to Christ's Hospital in so-called "Gothic." The new courts of St. John's College, Cambridge, described as "a monstrous pile of ugliness," were put up by Thomas Rickman the Quaker, to whom we owe the invention of the nomenclature of the English periods of architecture in his "Attempt to Discriminate," published, with "The Classic Orders" as a preface, in 1819. Porden had built Eaton Hall, and Atkinson, a pupil of Wyatt, carried out "Abbotsford" for Sir Walter Scott. Augustus Pugin with Le Keux informed and educated the public by their illustrations of Normandy and other mediæval work, thus paving the way for the turbulent crusade against Pagan inconsequence so vigorously undertaken by Welby Pugin, whose graphic "contrasts" and "true principles" did so much service later. His energy was attributed to what "Classicists" called his "Whimery," while his critics applied to him the sobriquet of "Smell-fungus," and so "the battle of the styles" began.

Prout and Piranesi.

But what man of his century dreamed of the exquisite beauty existing in the neglected smaller Tudor and Stuart-built dwellings of the husbandman before Prout made his brown-ink and reed-pen "dotted and blotted sketches"? Piranesi, no doubt, and Rembrandt too, with such studies as his "Mill," had extended influences, like Cotman and others, towards a truer appreciation of the higher forms of architectural picturesqueness, and Piranesi's Baroque compositions told in an imaginative direction. "The Beauties of England," edited by Britton and illustrated by Prout, fulfilled a mission in the way I have indicated, at a time when our forefathers displayed an intense ignorance of architecture.

Piranesi had a hand in illustrating the famous book by Adam on "The Palace at Spalatro," issued ten years anterior to the birth of Prout, when Bartolozzi did the engraving, but this work was beyond the range of ordinary people. At this time in France the reign of sound and considered Classic, inaugurated by François Mansart, who flourished at the same period as Inigo Jones, had well-nigh run its course, and things were shaping architecturally towards the chilly, pompous style of the Empire, which in a way was based on Palladian lines. Wood of Bath and Le Roy of Paris exemplified the spirit of refinement in design which found expression in France by the buildings designed by Gabriel, also in London and Edinburgh by Robert Adam, the most tasteful architect of his day, but his manner for varied reasons failed to find many imitators. The Adelphi Adams were extensively engaged at the time by the nobility, and by speculating, too, on their own account. Thus they enjoyed opportunities denied to Stuart and Revett, while Joseph

Bonomi only had a restricted practice, in which his skill was always manifest.

The London Squares.

Thomas Leverton did more, and was associated with the lay-out of London squares. Sir John Soane, the master of commonplace Greek, and Professor at the Academy, designed a scheme for the House of Lords, was much in favour, erected the Bank of England, and left a most excellent museum. John Gandon, pupil of Sir Wm. Chambers, displayed a much higher capacity when he won the competition and built the Custom House and Four Courts at Dublin.

Brighton Pavilion.

The culminating extravagances of George IV. were encouraged by John Nash when building the Regent's fabricated plaster palace, known as the Royal Pavilion, Brighton. This vogue for extraordinary diversions was thus exploited, but it was not all vulgar, and many of the appointments in glass, both in form and colour, were most clever; also the grotesque gilded carvings in this seaside palace were in their way excellent.

Work in the West End.

A few West End residences of the same decade as S. P. Cockerell's mansion for the Bishop of London, in St. James's Square, show the same distinction, but there was a prosaic order and colourless proportion about the decorous façades. James Wyatt, flattered by Walpole for his Gothic work, following up the Græco-Italian style, designed the "Pantheon" in Oxford Street; and Wyatville, R.A., invested, amidst Edwardian surroundings, the incongruities of the Empire style at Windsor. His diploma drawing at Burlington House, showing a bird's-eye outlined view in vista of a mansion for the Earl of Yarborough, dated 1826, is no mean performance. W. Wilkins, R.A., built the National Gallery in 1832, and the British Museum, by Sir Robert Smirke, was commenced in 1823. John Dobson, of Newcastle-on-Tyne, erected the famous station there, and laid out the town for Thomas Grainger. Dobson, by the way, was the first architect allowed to exhibit a coloured drawing at the Royal Academy. Up to 1815 architects had to be content with black-and-white drawings.

Soane's Churches.

Whatever niche may be accorded to Sir John Soane in architectural history, he will not be best remembered by the box-like galleried tabernacles which he put up. St. Peter's, Walworth, filled him with such pride that he reproduced it later at Holy Trinity, Marylebone. The church was one of his best, and Walworth, in 1824, when it was built, ranked as a fashionable suburb for the residences of merchants. Having had to alter the interior and re-seat it, I may mention an amusing incident. It so happened when Soane put up the organ in the west gallery the ceiling proved too low to allow of the bigger pipes being erected, consequently a sufficiently big hole was cut out in the plaster to give the pipes head room, and for over seventy years their volume of sound expended itself in the roof midst the owls and the bats, and no one below a penny the wiser! I only ascertained the fact when the organ was removed to the choir end of the church.

The Inwoods, Wilkins, Barry.

St. Pancras parish church, by the Inwoods, in 1822, famous for its Greek

*Extracts from a paper read before the Glasgow Institute of Architects, February 14, on "Architects from George IV. to George V."

style, of course leaves Soane miles behind; but then St. Pancras Church cost £100,000, and Marylebone Church cost nearly as much. University College, Gower Street, by W. Wilkins, dates from 1827. Two years later the Travellers' Club displayed a remarkable departure by Sir Charles Barry, who had then returned from Italy fully impressed with the Farnese Palace, and Wolfe, a pupil of Gwilt, had systematised his method of study, inducing him to forgo his fancy for Egyptian hieroglyphics covering mural surfaces with enrichments. Thus inspired from Italy, Barry also designed the Reform Club in 1837, and Bridgewater House in 1847. His early taste for redundant ornament reasserted itself in Barry's Gothic work.

Public Buildings.

Liverpool was ennobled by the building of St. George's Hall, H. L. Elmes, a pupil of his father, being its architect, who died early. By his last wish Professor Cockerell finished the building. Cockerell, foremost as a brilliant "scholar architect" and exponent of the higher school of the theoretical Classic, erected the Taylorian Building at Oxford. George Basevi carried out the structural shell of the noble Fitzwilliam Museum at Cambridge, and laid out Belgrave Square. Hyde Park screen, witnesses to the refinement of Decimus Burton, the architect of the Athenæum and United Service Clubs, Pall Mall. Sir William Tite commenced the Royal Exchange in 1844, which, it is said, owned a natural parent not recorded in the register. The west side of Somerset House was added a little earlier by Sir James Pennethorne. A considerable influence on façade treatment about this time was due to stucco.

Professional Charges.

As Government architects, John Nash, Sir John Soane, and Sir Robert Smirke had a retaining salary of £500 a year, and when any work of consequence was done they were paid 3 per cent. on the total cost of the building which either of them had to do with. At Buckingham Palace Nash was paid 5 per cent. after 1826, when the salary was dropped, and Blore had the same when he built the last front in Buckingham Palace Road. Wyattville received 5 per cent. for his Windsor Castle job, but that included the cost of coaches to and from Windsor. This expense must have been a considerable item for a man of his style and the conditions of travelling then. Sir Charles Barry made a bad bargain over his fees for the Houses of Parliament, having at the initial stage of his appointment agreed to a fixed fee of £25,000, but at that time the estimated cost was £800,000, exclusive of fittings and furniture, whereas the cost came to about £1,600,000, and the work took almost a lifetime to execute. Pugin was paid £200 a year by the Government to help Barry, who up to 1849 had furnished between 8,000 and 9,000 drawings. He also paid for some 3,000 casts of mediæval ornament. Ultimately, after years of negotiations and petty wranglings on the part of various Ministers of State, he had to be content with £25,000 and percentage grudgingly added for measuring and on the cost of various heating projects which had given the architect endless trouble. Other architects were paid 5 per cent., as in the Pavilion at Brighton, British Museum, National Gallery, and Kensington Palace. Sir Gilbert Scott's fees on the Home and Colonial Offices in Whitehall were 5 per cent., but he had to prepare several

schemes to satisfy Lord Palmerston, who obliged him to give up the Gothic design by which he won the competition in 1856 as settled by a Commission. The awards really were in favour of H. B. Garling for the War Office, and Coe and Holland for the Foreign Office; Scott being put third, while Sir Digby Wyatt was put in for the India Office. The cost of the Law Courts in the Strand came to £871,966, on which amount G. E. Street was paid £35,000, or about 4 per cent.

Progress of Gothic.

The Gothic Revival, as we have already said, was a tangential departure, and not an evolution by which in imperceptible degrees one style grew out of another. Pugin, with his doubtful analogies, and Ruskin, with his false taste for naturalesque sculpture in ornament, had at least instructed and roused public opinion. Time, and the erection of the new Palace at Westminster, aided by the Oxford Movement, opened up an opportunity for newer notions. Religious worship inspired the pious poems of John Keble, and the Tractarian influence of Froude, Newman, Pusey, and Hope gave a progressive power to church and college building. James Savage had some time before built St. Luke's Church, Chelsea, 1824; St. Peter's Church, Brighton, by Charles Barry, followed, in 1826; and J. C. Buckler designed Costessy Hall, Norfolk, 1825.

R. Abrahams had built the Middle Temple Library, Welby Pugin had designed St. George's Cathedral, Southwark, in 1845; while in the same year the Church of St. Stephen, Rochester Row, was built by Benjamin Ferrey, the year following the erection of St. Andrew's Church, Wells Street, by S. W. Dawkes. The Hall and Library in Lincoln's Inn Fields, by P. Hardwick, date from 1843, though it is said he did not really design them. When the Government advertised the Houses of Parliament competition in 1835 the conditions prescribed "Elizabethan or Gothic." Four premiums of £500 each were offered, and ninety-seven competitors sent in plans. Charles Barry won the prize, and was forty years of age when King William IV. confirmed the award of the Commissioners and elected him architect early in 1836.

While Pugin was busy in 1837 with the drawings of the new Palace at Westminster, "in the composition of the river front," the centre wings and tower, he was engaged in erecting St. Mary's College, Oscott, and Scarisbrick Hall. His first church was St. Mary's, at Derby, and he carried out work all over the United Kingdom. The Pugin Travelling Studentship, founded by subscription at the R.I.B.A., was first held in 1865, by Mr. Tavenor Perry, who built part of the Hotel Cecil, facing the Embankment.

Sir G. G. Scott.

Sir George Gilbert Scott, at the outset of his career, erected many workhouses and such-like buildings, as did other Gothic celebrities, like S. W. Dawkes, who had erected Colney Hatch, and Benj. Ferrey, who built Dorset County Hospital in 1839. Scott was articled to Edmeston in 1827, and in 1834 helped Kempthorne, an expert in workhouse projects, after serving a time with the builders, Peto and Gissell. Scott's connection with Moffatt began in 1835, after which the firm went in seriously for Poor Law enterprises, and carried competitions before them with business-like foresight in such a way as to obscure some other considerations. Influenced by Storer's "Cathedrals,"

which came out in 1826, Scott turned his attention subsequently to mediæval work.

[Scott's work was reviewed at considerable length, and the lecturer did not fail to mention that it was Scott who, in 1851, founded the Architectural Museum.]

Architectural Institutions.

The professional societies of architects must not be overlooked. The first date from 1806, with John Woods, architect, George Yard, Lombard Street, as president. James Savage and James Elmes were the vice-presidents, Mr. Bushe being the secretary. Every member was expected to present annually an essay on a subject connected with civil architecture, or forfeit half a guinea.

The Royal Institute of British Architects was constituted in 1835, and incorporated in 1837. Its genesis may thus be briefly stated. On January 8th, 1833, a meeting took place, in Freemason's Tavern, of architects and surveyors, who found an architectural institution. Mr. Elmes took the chair at a subsequent meeting on the 13th of the same month when it was agreed to term the institution "The Society of British Architects." In 1835 "the Architectural Society," instituted in 1831, only numbered fifty-one members at 35, Lincoln's Inn. Mr. Bernard Clarke was the president. In 1838-9 Sir William Tite was president and Richard Halliwell honorary secretary. The Society of Architects and Surveyors and the Society of British Architects formed a coalition in 1842. The first meeting of the Institute, however, met at "The Thatched House Tavern," Strand, James's Street, in July, 1834. The opening general meeting was held in July, 1835. The Society of Architects in its revived form was started in 1884.

William Butterfield.

William Butterfield is first found recorded as a student member of the Society of Architects in 1831, at the age of seventeen, but he joined no professional body after, and only agreed to accept the Royal Gold Medal of the Institute in 1884 as deputy. His influence was considerable and his work masterly. The College of St. Augustine at Canterbury, built in 1845, was his first important building. All Saints' Church and Clergy House, Margaret Street, five years later, revealed the possibilities of brick, and created much controversy. St. Matthias', Stoke Newington, Balliol College Chapel, Oxford, and St. Alban's Church and Clergy House, Holborn, 1858, displayed his genius. Keble College, Oxford, was erected in 1867. Not one of Butterfield's contemporaries evinced more originality or less regard for convention. He invented the "streaky-bacon style" of partially coloured brickwork, and was so enamoured of his patternings, that finding creeper growing on the walls of one of his buildings, he had them cut down and concrete added round the footings to prevent any such growth hiding his work in future.

J. L. Pearson, J. P. St. Aubyn, James Brooks.

John Loughborough Pearson, R.A., was equally original, and produced buildings unsurpassed by any man of his time. The spire of his first London church, Holy Trinity, Bessborough Gardens, 1852, is a most beautiful structure seen from any point of view; and St. Peter's, Vauxhall, the first modern church vaulted throughout in brick and stone, 1864, set an example for many others to follow. St. Augustine's, Kilburn

St. John the Evangelist, Red Lion Square, St. Michael's, Croydon, St. Agnes, Liverpool, St. Matthew's, Northampton, and St. Stephen's, Bournemouth, as well as Hove Parish Church, not to mention Truro Cathedral, suffice to distinguish Pearson as a master of the first degree, combining a study of Continental work with a recognition of English tradition, and as a church-builder fully realising the requirements of a modern church. The Catholic Apostolic or Irvingite Church at Maida Vale was one of his latest buildings. Raphael Brandon's church in Gordon Square, for the same body, opened in 1854, has never been surpassed for its similitude to a mediæval building of cathedral-like proportions. Mr. John Belcher supervised the Early English carving of the capitals of the interior a few years ago.

J. P. St. Aubyn was among the first English architects of the Gothic revival to recognise the importance of local modes and texture, his church work in Cornwall being studied in this way.

The series of churches built by James Brooks rise to the level of high distinction. He built, in East London, St. Michael's, Shoreditch, St. Chad's, Haggerston, and St. Columba's, Kingsland Road, during the 'sixties; and the Hospital of St. Mary at the Cross, Shoreditch, and St. Saviour's, Hoxton, St. Andrew's, Plaistow, and St. Mary's, Hornsey, in which church Brooks tried his hand at the last phase of Gothic—the Perpendicular. St. John's, Holland Road, is one of Brooks's most noble buildings.

Bodley and Burges.

G. F. Bodley, R.A., stamped everything which he did with the utmost refinement and distinction, as well as much originality, which would have graced any period of architecture. St. Michael's, Brighton; All Saints', Cambridge; the Church of the Holy Angels, Hoar Cross; St. Augustine's, Pendlebury; St. Mary's, Clumber; St. John's, Cowley, Oxford; St. Edward's, Holbeck; and Holy Trinity, Kensington, give an abstract of several remarkable examples of beauty and reserved power. River House, Chelsea, the School Board Offices on the Embankment; Christ Church Buildings, and St. Swithin's Quadrangle, Magdalen College, Oxford; King's and Queens' Colleges, Cambridge; and Washington Cathedral must suffice. His character was as charming as his work, and no one had a wider experience in perfecting design in the applied arts. Part of the work mentioned was done, of course, in conjunction with Thomas Garner. Bodley's reredos at King's Lynn is only one of similar erections of his. When he was elected A.R.A. he told me his works sent to the R.A. for exhibition were refused by the Council because they said his share of the designs must pass without question, and Mr. Garner's share of them must be judged. This absurd contention much amused Bodley. William Burges's wonderful house at Melbury Road is worthy of belonging to the nation. William Burges joined H. Clutton in a competition for Lille Cathedral in 1856, which they won. Street took the second prize.

The church at Lille is a wretched building, boiled down from Burges's and Street's designs, and erected by a local man named Leroy, Burges and Clutton have been got rid of. The designs of William Burges were always thorough, including the most minute detail. Cork Cathedral, his churches at Skelton and Studley Royal near Ripon, Cardiff Castle, St. Faith's, Stoke Newington, the Speech

Room, Harrow, are among the most important. His design for the Law Courts was architecturally by far the best. The scheme which he made for decorating St. Paul's Cathedral by a veneer of marble was shown at the Royal Academy in 1873. Burges's design for Edinburgh Cathedral would grace any period of art.

E. W. Godwin.

E. W. Godwin, F.S.A., like his personal friend William Burges, imported French Gothic mannerisms, and exercised a great influence on his fellows, though considering his genius, Godwin's career individually was largely a failure. Congleton and Northampton Town Halls, Dromore Castle and Glenbigh Towers, some work at Canons Ashby for the Marquis of Northampton, are his designs. He won the first competition for the Town Hall at Leicester, and built Whistler's house at Chelsea, and others at Bedford Park. Godwin created a style of his own, and took up Japanese art with ability. As a writer of literary accomplishment and as an authority on costume and dramatic staging he was unsurpassed.

G. E. Street.

George Edmund Street, R.A., the builder of the Law Courts, was in every sense a great architect. His books on Spain and Italy's architecture of brick and marble display indefatigable industry and a discriminating incisive style. Bristol and Christ Church Cathedrals were partly rebuilt by him. His design for Edinburgh Cathedral was an excellent performance; a remark which applies to his fine churches at Kennington, Paddington, Eastbourne, Clifton, Bournemouth, and Oxford; also St. James-the-Less, Westminster, and the Convent at East Grinstead. Like Barry and Scott, Street was buried in Westminster Abbey. Bodley designed the brass over his grave.

G. G. Scott, Junr., and J. D. Sedding.

The enormous advance in church development and planning throughout the time just considered was further extended by others. George Gilbert Scott, junr., as he was called, erected St. Agnes, Newington, in 1877, and All Hallows, Southwark, some years later, realising the poetry and efficiency of ecclesiastical work of a plainer kind in brick for the purposes of town churches and advanced Anglican worship. J. D. Sedding's two London churches, Holy Trinity, Sloane Street, and that of the Holy Redeemer, Clerkenwell, are exceedingly clever and well contrived, though so different, showing a quality of mind and versatile taste, therefore somewhat disappointing.

J. F. Bentley.

J. F. Bentley's smaller churches were very charming, and the Cathedral at Westminster will hand his name down to posterity, though it is doubtful if it will ever look so grand inside as now in the undecorated plain carcase state with the brick joints to give it scale. His seminary of St. Thomas at Hammersmith, though so plain, is a greater success than his florid college near Windsor.

Some Civic Buildings.

Briefly let us turn to Civic Buildings, in which connection the Town Halls of Leeds and Hull, by Cuthbert Broderick, come to the mind for their classic merit, which also marks John Burnet's works in Glasgow, with many others of no small ability in Scotland, as at Aberdeen and Edinburgh. Greek Thomson, too, had his admirers, though his work leaves me cold. Banks and Barry's buildings, form-

ing the quadrangle in front of the Royal Academy and the Palladium buildings at its rear for London University, by Sir James Pennethorne, were erected in 1868; the City Liberal Club, by Mr. G. E. Grayson, a few years later. David Bryce erected the Bank of Scotland, and J. Dick Peddie's work will recall with praise; also E. M. Barry will not be overlooked. Alfred Waterhouse, R.A., of stupendous practice, was no sooner out of his articles than he won the Assize Courts at Manchester. The planning of Manchester Town Hall demonstrated the unequalled skill of Waterhouse as a planner, and as a water-colourist he was graphically artistic. His buildings all over the kingdom speak of him as an architect, and the Natural History Museum, if hard in material texture and not very happy in its colour, is not put out of countenance by its newer neighbours.

Domestic Work.

English and Scottish domestic work has exceeded in merit all foreign competition, and it bids fair to reach a more general application as men learn to omit senseless detail and elaboration, depending instead more on outline and good proportion; but the Gothic spirit must be retained to keep it virile and adapted to modern requirements and domestic comfort.

BOOKS.

"Should We Stop Teaching Art?"

We do not quite see the point of Mr. Ashbee's title, unless, indeed, it is intended to arouse curiosity, and thence promote purchase, as a piquant and startling title often does. For the book is really a good deal occupied with what the author seems to regard as better methods of teaching art, or at least one art, that of architecture; though it is not very easy to make out what is the real intention of his rather rambling argument. He tells us on one page that the profession of architecture "is still wedded," and rightly, "to the apprenticeship system," but in the next sentence he tells us that the apprenticeship system is worn out, and that all who have gone through it in architecture know that they cannot get from it what they need. What the young architect really suffers from, we are told, is a lack of systematised study and training. "The routine of the office does not give it him, for it is routine; the Royal Institute examinations do not give it him, for they are examinations; the Polytechnic—even the Central School of Arts and Crafts—classes do not give it, for they are classes; and finally the art school does not give it, for it is just an art school." What is the meaning of the omission of all mention of the Architectural Association School? Is Mr. Ashbee really ignorant of its existence, or is the omission intentional? If the latter, some explanation is certainly required.

We can better understand the meaning of the title of the book in regard to the second chapter, on "the province of the Royal College of Art and the problem of the art school." What is meant is that the art schools should be not schools of drawing, designing, and modelling, but artistic workshops; and there is certainly point in the figures given, that out of 459 students trained during ten years in the College of Art, only 32 have made the practice of art in any sense their livelihood, and 126 earn their living as teachers; the remainder, we presume we

are to understand, have not been heard of since in any connection with art. That is certainly rather a serious state of affairs, and seems to mean that the College of Art provides teachers of art in far greater proportion than actual artists; a result which, if it goes on in the same ratio, would lead us presently to a land full of teachers of art with no one to be taught. The natural explanation, of course, is that a man can live better on an art-teacher's salary than he can on his earnings as a producer of artistic work. There must, however, be some teaching of design and drawing before students can become real artisans in applied art. Beyond that, there is some reason in the proposal gradually to change the system of endowment of our art schools into a system for the endowment of small artistic workshops. This might lead also to larger employment in our manufactures of the work of students in such schools. We know that at present many manufacturers say that the designs made by students in the national art schools are not of any use in the market, probably because they are designs based on a theoretic system which is not sufficiently in touch with actual processes of manufacture.

In this portion of the book there is a definite and intelligible purpose. As far as architecture is concerned we do not see that there is. The only definite point that we can lay hold of is that in America architecture is recognised as a university subject, and in England it is not; and we are told that a certain superiority in American architecture—"a greater sweep, a more logical planning, a wider outlook"—is due to this university training. We were under the impression that American architecture owed more to the *Ecole des Beaux-Arts* than to any American university. And in any case this desire for university training seems rather incompatible with the tendency in other pages of the book to connect architecture more closely with an "Arts and Crafts" training.

Should we Stop Teaching Art? By C. R. Ashbee. London: B. T. Batsford; 1911. Price 3s. 6d.

Architectural Hygiene.

This book, of which a fourth edition, revised, is now before us, gathers together and digests into convenient and connected form the scattered but authentic information relating to sanitary science as it affects architects and others concerned in rendering buildings healthily habitable. The first chapter deals with sanitary legislation, and summarises, or describes the effect of, the seven Acts that bear more or less directly on the subject of sanitation. Thence the authors proceed to deal, in due sequence, with hygienic principles in relation to construction; site and foundations being first considered, then planning, and afterwards sanitary construction. General principles having been thus enunciated, the major part of the book is occupied with details of house drainage, drain ventilation, sanitary fittings, refuse and sewage disposal, ventilation, heating, water supply, and lighting. Sanitary inspection, and surveys and reports, are dealt with in successive chapters, model reports showing exactly how the observations should be recorded. The actual sanitation of a country house, and the lighting, heating, and ventilating of a city company's banqueting hall, are described and illustrated in full detail; and altogether the book will be found serviceable, not only as a text-book for examination candidates, whose requirements have evidently been kept in view

throughout, but also as a handy compendium for the architect and the sanitarian.

Architectural Hygiene; or, Sanitary Science as Applied to Buildings. Written and fully illustrated by Banister F. Fletcher, F.R.I.B.A., etc., and H. Phillips Fletcher, F.R.I.B.A., etc. Fourth Edition, revised. Pages xii+284, 7½ ins. by 5½ ins. Price 5s. net. London: Whittaker and Co., 2, White Hart Street, Paternoster Square, E.C.

An Architect's Guide to Canterbury.

It would be interesting to know in what numerical proportion guide-books stand relatively to the general output of books. Surely guide-books must stand at the head of the list; and also it seems certain that no other class exhibits so great a variety of physical form and literary, or, alas! unliterary, treatment. They range from expensive sumptuousness to cheap squalor, their prices being a matter of pounds or a matter of pence. Yet it cannot safely be said that we have already guides enough and to spare. Those of the cheaper sort are usually thrown away immediately after they have served the purpose of the visitor, who buys another when he again visits the same spot; hence the continuousness of the supply, and hence we are disposed to welcome the projected "Tourist Cathedral Series," even though the first subject chosen is the somewhat overdone cathedral of Canterbury. The projector of the series is an architect, and his guide to Canterbury reveals many agreeable indications of that important fact. It is surprising, indeed, when one comes to think of it, that relatively so few guides are prepared by architects. In Mr. Seager's guide, the architectural point of view is always considered, without undue stress being laid upon it; and the peculiar advantage is that both laity and profession may rest comfortable in the assurance that, in describing the features of the building, the author knows quite well what he is talking about. In other respects also the guide is honourably distinguished from the general run. The arrangement is orderly and progressive, the language is terse and clear, and the illustrations, reproduced from photographs by the author, show an unusually informative—as distinguished from the purely pictorial—interest. Some valuable "links in the development" of vaulting, piers, windows and their tracery, foliated capitals, and the arch, are appended. A brief bibliography includes the following reference: "For further information on the Towers of Canterbury the reader is referred to an illustrated article by W. D. Caröe, Esq., F.R.I.B.A., published in the 'Architectural Review' of January, 1905."

The Tourist Cathedral Series. Canterbury Cathedral. By S. Hurst Seager, F.R.I.B.A. Illustrated with forty-nine photographs specially taken by the Author. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. Pages xvi + 120, 6½ ins. by 4½ ins., price 1s. 6d. net.

Artistic Stencilling.

The most vehement opponent of stencilling might well be converted to at least a less positive opinion upon it after reading the *apologia* which is so persuasively set forth in this book, and more especially after seeing the really beautiful examples which it illustrates. Those who are undecided as to whether or not they should lend countenance to this means of decoration will doubtless, in most cases, be won over to the more liberal view, more particularly since the authors are able to show that the art is no mushroom growth, but that, on the contrary, it is of very respectable antiquity. "We are strongly of opinion," they say, "that stencilling was largely used by Persian decorators in some descriptions of orna-

mentation"; and though they admit that they are unable to point to direct evidence of its employment in this connection, they contend, reasonably enough, that instances of absolute accuracy in repetition are pretty sure evidences of stencilling. Much attention is given to Japanese stencilling, "simply because it is the only school of the art from which inspiration and valuable instruction can be acquired." The materials and the process of stencilling are fully described; and, as we have said, the examples illustrated—several of them in beautifully harmonised colours or tints—will probably win over many waverers to the belief that stencilling is an unduly despised and an unjustly neglected art.

Artistic and Decorative Stencilling. A practical Manual on the Art of Stencilling on Paper, Wood, and Textile Fabrics, for Home Adornment and Articles of Dress. By George Ashdown Audsley, LL.D., Architect, and Merthold Audsley, Architect. Illustrated with twenty-seven Plates in Colour and Monochrome, and Engravings in the Text. London: George Allen and Company, Ltd., 44 and 45, Rathbone Place. Pages viii + 80 + 26 Plates, 8½ ins. by 5½ ins., price 4s. 6d. net.

IN PARLIAMENT.

(By our Press Gallery Representative.)

Stone for Redford Barracks.

Mr. Tennant has informed Captain Gil'mour that the stone for the ashlar and rubble work for the new cavalry barracks at Redford, near Edinburgh, is obtained, as regards ashlar, from the Blackpasture Quarry, Northumberland, and as regards rubble, from Doddington Quarries, Wooler, Northumberland.

Victoria Barracks, Windsor.

Colonel Seely stated, in reply to Mr. James Mason, that the actual price paid by the Government for the freehold property acquired for the extension of the Victoria Barracks at Windsor, including costs, etc., was £40,124. The cost of erection of buildings was £54,500, besides £3,100 for improving the married quarters.

Portsmouth Town Planning Scheme.

Viscount Wolmer asked the Under Secretary of State for War whether the War Office had recently had applications made to them to sell land in the vicinity of Portsmouth for the purpose of small holdings, in order to permit the city to expand; whether these applications had been refused; and, if so, on what grounds had the Government been holding up this land?

Colonel Seely, in a printed reply, stated:—The question apparently referred to a scheme for town planning recently started by the Corporation of Portsmouth which included a considerable area of War Department land. No details of the scheme have as yet transpired, and the Corporation have been informed that until the department had further information as to what was proposed must withhold its consent to the inclusion of War Department property.

Bricklayers and Slate Work.

Mr. Carr-Gomm having asked the Secretary to the Admiralty whether his attention had been called to the fact that the stripping and re-slatting of roofs at the Royal Victualling Yard, Greenwich, Deptford, had for some years been carried out by bricklayers,

Mr. Lambert stated that bricklayers had been employed on certain small odd jobbing work, which included slating, Deptford. The work did not warrant the employment of slaters, but men in this trade would be employed for an extensive work.

NEWS ITEMS.

The New Recreation Hall, Southall.

In our description of the new Recreation Hall at Southall, illustrated in our last issue, it should have been stated that the heating, hot-water supply, and cooking apparatus were installed by Messrs. Benham and Sons, Ltd., 66, Wigmore Street, W.

A Frank Bramley Exhibition.

Mr. Frank Bramley, R.A., has been at work for the last three years in preparation for a "one-man" exhibition—the first he has ever held—and it is to take place shortly at the Leicester Galleries, Leicester Square. Since Mr. Bramley painted "The Hopeless Dawn"—now in the National Gallery of British Art—his style has considerably changed, and the fifty canvases by which he will be represented in the coming exhibition will be for the most part in his later, and perhaps more vigorous, manner.

Suggested Traffic Board for London.

At last week's meeting of the London County Council, a recommendation of the General Purposes Committee with reference to a suggested Traffic Board was discussed. The Committee recommended that the Prime Minister should be asked whether the Government proposed, as the result of representations made by the Council in 1907, to introduce legislation on the lines of the report of the Royal Commission on London Traffic to establish a Traffic Board for London. An amendment brought forward by Sir John Benn having been defeated, the recommendation was adopted.

Excavations at St. Bartholomew-the-Great, Smithfield.

The excavations which have been made at the Church of St. Bartholomew-the-Great, West Smithfield, have proved very successful, the foundations of the old chapel attached to the old Augustinian Priory which existed on the site having been discovered under what is now the Lady Chapel. The foundations, however, have not been laid bare, and it has not been necessary to make any extensive excavations, as the object in view was merely the verification of an old ground plan in which the chapel was shown, for insertion in a history of the church which is in course of preparation.

New King's College Hospital at Denmark Hill.

Although the new King's College Hospital at Denmark Hill is not expected to be finished until early in 1913, the building has now assumed proportions that convey a good idea of the undertaking. Apart from out-patients, the hospital is designed for the accommodation of over 600 patients, and there is living room for 300 nurses. The south frontage, measuring 1,200 ft., is taken up by a row of eight wards, the centre two of which are three-storey buildings, while the others are of two storeys. On this side, too, there is a large central station which will be fitted with boilers and oil engines for the domestic requirements of the hospital. All the consulting-rooms are grouped around a large waiting-hall. They are so planned that patients, after receiving attention, will not need to retrace their steps, but will find their way out past the dispensary. The bathing department is also near the waiting-hall.

On the first floor are a dental department, with a north light, and an electrical section with special rooms for Finsen light and other special forms of treatment. The observation ward is planned on the cellular principle, after the model of the Pasteur Institute in Paris, but with improvements in detail. It consists of eight single-bed wards, separated from the corridor by glazed screens. The isolation block is in the north-west corner, and the surgical arrangements include several modern operating theatres and a number of laboratories. The architect is Mr. W. A. Pite, F.R.I.B.A.

Russian Architecture.

So little attention has been paid in this country to the architecture of Russia, that a comprehensive survey of the subject should contain a great deal of fresh interest. We have received an illustrated prospectus (in Russian) of a volume in which the "Architecture of the Eighteenth and Nineteenth Centuries in Russia" (1700-1840) will be described and illustrated, the 400 pictures including many hitherto unpublished designs by eminent Russian and foreign architects. Apparently the volume is being prepared under the authority of the "Society of Russian Architect-Artists." The illustrations shown in the prospectus give promise of a work of exceptional interest.

Business Change.

It is announced that for family reasons the business carried on for the last 60 years in the successive names of A. E. Burrell, A. E. Burrell and Son, and for the past 37 years as Burrell and Co., has been converted into a private limited liability company, the first directors being: Edmund Risolière Burrell (chairman), Percy Edmund Burrell, and Keith Burrell; all of whom will sign as joint managing directors. The new company takes over the late firm's liabilities. The company has been so constituted that the whole of the issued capital remains in the hands of the family, thus providing for a continuity of control. The address of Messrs. Burrell and Co., Ltd., manufacturers of varnishes, colours, enamels, etc., is Tower House, Trinity Square, London, E.C., with works at Burrell's Wharf, Millwall, E.

Sheffield University Department of Architecture.

Soon after the formation of the Department of Architecture at Sheffield University, it was considered advisable to organise vacation courses at places in which buildings of architectural importance could be studied by means of the making of sketches and measured drawings, and to make attendance at a certain number of these courses compulsory for students working for the diploma in architecture awarded by the university. The vacation course for Easter generally begins about the end of March, and lasts from a week to ten days, while the summer course begins about July 8th, and lasts from three weeks to a month. Permission to sketch and measure a series of important buildings is obtained, all difficulties as to the use and hire of ladders, etc., are avoided, and an instructor is present with the students to give such advice and guidance as may be needed. The Easter course will be held in Bath this year, beginning on March 23rd. Permission to sketch or measure at several important buildings, including the Abbey, Prior Park, Ralph Allen's

town house, the banqueting-room of the Guildhall, and No. 24, Queen Square, has already been obtained. A visit will be paid to one of the quarries belonging to the Bath Stone Firms, and at the beginning of the course a lecture on the architecture of Bath will be given by Mr. Mowbray A. Green, F.R.I.B.A., vice-president of the Bristol Society of Architects. For the summer course, a sketching and measuring tour in Northamptonshire will probably be arranged. The lecturer in the Architectural Department of the University is Mr. W. S. Purchon, A.R.I.B.A.

ACQUISITION OF STEVENS
COLLECTIONS

The Victoria and Albert Museum has recently acquired a considerable number of drawings and designs by Alfred Stevens from the collections made by two of his pupils, James Gamble and Reuben Townroe, both of whom died in the early part of 1911. These have now been mounted and labelled; and a selection has been placed on exhibition in Room 75, advantage being taken of the opportunity to rearrange the drawings by Stevens already shown there, which are now grouped according to subject throughout the gallery. Designs for the decoration of St. Paul's Cathedral form one of the most important sections of the exhibition, the various studies in red or black chalk or pencil being illustrated by tracings made by Townroe and Stannus of the completed designs. The designs and studies for the decoration of Deysbrook have also been brought together, and are now supplemented with several full-size working drawings of details in colour, which have not before been exhibited. One of the most interesting of the new acquisitions in this class of work is a sketch in water-colour for the decoration of a staircase and landing of a public building. The Museum has acquired several early studies, both of landscapes and from works by old masters, made by Stevens during his first visit to Italy, among them being small copies in water-colour of Titian's "Flora" and "Eleanore Gonzaga."

The collection also includes studies in black chalk for the decorations of Dorchester House, and designs for silver-smiths' work, candlesticks, street-lamps, pottery, and stoves, as well as a large number of slight sketches of architecture and furniture and memoranda of subjects for figure compositions. The Museum now possesses upwards of 500 drawings and studies by this distinguished British artist; those not exhibited in Room 75 (or Room 48, where a series related to the Wellington Monument has been hung) being obtainable on application in the Students' Room (71) of the Department of Engraving, Illustration, and Design.

This department has also recently acquired a valuable series of original drawings by Randolph Caldecott, made as illustrations to "Breton Folk" (1880); and a volume of fanciful pen-drawings by Richard Doyle, entitled "A Book Full of Nonsense. By Dick Kitcat." dated 1842, but not published. Both these valuable accessions are due to the generosity of Sir Edwin Durning-Lawrence, Bart. They are exhibited in Room 70, where are also placed fifteen original studies by the late Sir Francis Seymour Haden, P.R.E., of which eight were presented by F. Seymour Haden, Esq.

MANCHESTER BUILDING TRADES
EXHIBITION.*Messrs. D. Anderson and Sons.*

The specialities D. Anderson and Sons, Ltd., are exhibiting at the Building Trades Exhibition in Manchester, which is being held from March 5th to 16th, include their "Rok" roofing, which they have recently put on the market, after severe and exhaustive trials in India, and other countries where the conditions are far more severe than in England, and where it has come out triumphantly. In South Africa, the South African Union officials have passed it as meeting all their requirements of a roofing felt, and have given permission for its use on contracts to be executed for them. At home it has recently been used for roofing buildings for the Great Southern and Western Railway of Ireland, at Limerick; by Messrs. John Henry and Co., paper-makers, Thatcham, Berks; Messrs. Hutchinson, Hollingworth and Co., Dobra Loom Works, Dobra, Yorks; Siemens Bros., Ltd., Dynamo Works, Stafford; Whitehead Iron and Steel Co., Tredegar, Mon., and many others.

Messrs. Anderson and Sons are also showing their Stoniflex felt, which is now well known by architects and builders as a capital felt for roofing buildings, and also for sarking and lining.

Another new article they are showing is their "Zerolite" insulating paper for insulating cold stores and for lining purposes.

They are also drawing the attention of architects and others to the bitumen sheeting, made from pure Trinidad bitumen, which they are supplying for reservoirs, tanks, etc., and their pure bitumen dampcourse for walls.

Rolls of their bituminous hair felt, which, they state, is coming greatly into favour with architects for sound-deadening and sarking purposes, are on show. The article is vermin-proof.

Fencing treated with Messrs. Anderson's Sideroleum wood preservative is shown, and this also is an article that is now well known, being used throughout the country for this purpose, and also for half-timber work, sheds, etc.; for, besides being a preservative, it gives an extremely pleasing appearance, resulting from the beautiful nut-brown shade in which it is made.

The firm also show a range of galvanised sheets coated with "Siderosthen" anti-corrosive paints in various shades, which they commend to architects' attention as paint for galvanised iron.

Messrs. Vulcanite, Ltd.

Messrs. Vulcanite, Ltd., of Westinghouse Road, Trafford Park, Manchester, also at Belfast, London, Newcastle-on-Tyne, Glasgow, and Dublin, occupy Stand 56, which architects, surveyors, engineers, and contractors will find to be one of the most interesting in the exhibition. The exhibits include a model brick building with a flat roof tastefully laid out as a miniature roof garden, the roof being constructed of joists and 1-in. tongued-and-grooved boards covered with patent Vulcanite roofing.

Messrs. Vulcanite, Ltd., who are the sole patentees of this roofing, have covered roofs measuring in the aggregate upwards of 4,000,000 superficial yards, including some of the finest hotels, villas, works, and public buildings in the United Kingdom, the Colonies, America, and other countries, and they claim that their patent Vulcanite roofing is a perfect covering for

flat roofs of wood or concrete construction, inasmuch as it is absolutely waterproof and fire proof, and is not affected by expansion and contraction, vibration or settlement of the building.

The exhibit also includes a water tank, which is formed of 9-in. brick walls, the bottom and sides being lined with Vulcanite and afterwards bricked in with white glazed bricks. In order clearly to demonstrate the waterproof qualities of the Vulcanite, ordinary mortar only has been used, and an opening has been left in the glazed brick lining, leaving a portion of the Vulcanite exposed. This part of the exhibit will particularly interest municipal authorities, architects, surveyors, and engineers who are constructing swimming baths, reservoirs, etc.

Another interesting feature of the exhibit is "Bituna" pure bitumen dampcourse. This material, which is being specified by the leading architects for foundations, subways, arches, etc., is guaranteed to be made of pure Trinidad bitumen, with no admixture of coal-tar or coal-tar pitch. A section of a brick wall is shown standing in water with a course of "Bituna" about 6 in. above the water level. Underneath the dampcourse the bricks are soaking wet, whilst they are perfectly dry above, thus proving the efficacy of the "Bituna."

The firm are also exhibiting Vulcanite asphalte, and Rexilite dampcourses for foundations, etc., Leatherite, Vulcanite asphalte and Rexilite roofings for sloping and circular roofs, Vulcanite bitumen and Vulcanite waterproof sheetings for underlining slates, tiles, etc., and a model building covered with Rexilite. When viewing the latter, visitors will be struck with the neat and attractive appearance of the Rexilite, which is suitable for covering motor garages, billiard-halls, picture theatres, cricket and football pavilions, or any other building on which it is essential to have a perfectly watertight roof.

TRADE AND CRAFT.

The Lighting of Country Houses.

Probably many wealthy people, fearing the drawbacks of antiquated lighting and heating arrangements, hesitate to occupy country houses. Many people are unaware of the enormous strides which have been made in the last few years in electric generating sets, which have been brought to a surprising degree of simplicity and excellence in working. Messrs. Tredegar and Co., of 56, Victoria Street, Westminster, whose systems are in use in many of the most famous residences in the country, have a particularly effective plant, which can be installed in the oldest houses with perfect safety, and will provide light and heat for the house and power to work laundry, stable, and other domestic machinery. Their surface wiring system does away with the great damage to the walls which formerly was inevitable, and their artistic wooden fittings harmonise with any period of architecture. For those who prefer gas illuminant, they have equally effective acetylene and petrol air gas sets, which are also inexpensive to install. The working of any of these systems is simple in the extreme; and as this firm sends a competent engineer to instruct the gardener or coachman in the management of the engine, there is no fear of a breakdown through lack of proper knowledge and attention.

OBITUARY.

Mr. George Attwood.

Mr. George Attwood, who died on February 9th, at Steyning Manor, Stogursey, Somerset, was a member of the Institution of Civil Engineers and various other scientific and professional bodies. He began his professional career at the age of 16 under his father and Mr. W. W. Palmer, C.E., in California and Nevada. He constructed and designed large engineering works on the American Continent and in Africa, and practised as a consulting civil and mining engineer in London. He was the author of numerous scientific publications and papers.

Mr. G. E. Pritchett.

The death took place on February 23rd of Mr. George Edward Pritchett, F.S.A., of Oak Hall, Bishop's Stortford, in his 88th year. Mr. Pritchett was the oldest Old Carthusian, and was present at the recent Tercentenary Banquet. He was the architect of many churches in Herts and Essex.

Sir John G. N. Alleyne.

Sir John Gwyn Newton Alleyne, Bt., whose death recently occurred at Falmouth, was born in the year 1820, and succeeded his father in the baronetcy, created in 1769, in the year 1870. An engineer by profession, Sir John was an original member of the Iron and Steel Institute, and was, indeed, the sole survivor of the first council formed under the presidency of the seventh Duke of Devonshire, in 1869. He was a Vice-President of the Institute during recent years. Sir John was also a member of the Institution of Civil Engineers and the Institution of Mechanical Engineers. He was associated with many important railway contracts, including the building of the St. Pancras Station of the Midland Railway. Sir John was also responsible for the design of a considerable amount of colliery plant. He took much interest in certain branches of iron and steel research, notably the application of the spectroscopic to analysis; a subject upon which he contributed a paper to the Iron and Steel Institute.

Dr. Osborne Reynolds.

Dr. Osborne Reynolds, formerly Professor of Engineering at Manchester University, died recently at Watchet, Somerset. Born in Belfast in 1842, Dr. Reynolds was educated at Dedham Grammar School, afterwards proceeding to Queens' College, Cambridge, and graduated as seventh Wrangler in 1867. For nearly 40 years he occupied the Chair of Engineering at the Owens College. In 1877 he became a Fellow of the Royal Society, and in 1883-4 he served as member of the Council. In 1887 he became a sectional president of the British Association, and in the following year received a gold medal of the Royal Society. He wrote more than 70 papers on mechanics and physics, among which "The Laws of Resistance in Parallel Channels," "Theory of Lubrication," and "Flow of Gases" are familiar to all engineers. His work "Sub-Mechanics of the Universe," a volume printed and circulated by the Royal Society, is one of the most remarkable scientific works of the 19th century. Dr. Reynolds organised and arranged the Whitworth laboratories of the Owens College, Manchester, and made them not only famous throughout the world but a pattern for the other European schools of research.

THE ARCHITECTS' & BUILDERS' JOURNAL

WEDNESDAY,
MARCH 13th, 1912.

Volume XXXV.

No. 895.

CHIMNEYPiece IN DINING-ROOM, "DEYSBROOK," NEAR LIVERPOOL.

"Deysbrook," near Liverpool, an old house now used as a children's hospital, has been made notable by the painted decoration which Alfred Stevens carried out there. It also possesses this chimneypiece in what was formerly the dining-room, but is now the babies' ward. This is carried out in wood and is a vigorous piece of work, though tainted with mid-nineteenth-century feeling; "Deysbrook" having been built in the 'forties for the Blundell family.

Gwilt and His "Encyclopædia of Architecture."

WHILE so many books have been published of late years to give instruction in various branches of architecture, including dictionaries such as that brought out by the late Mr. Russell Sturgis, it seems desirable to recall to the recollection of architects and students one monumental work which in its way may be

said to stand alone among works in the English language, namely, Gwilt's "Encyclopædia of Architecture," first published in 1842, and followed by new editions in 1876 and 1888, enlarged and revised by the late Mr. Wyatt Papworth, and by him brought up to the date of the latter period with respect to the class of subjects about which experience and knowledge go on accumulating. A large proportion of Gwilt's Encyclopædia, however, deals with subjects—such as geometry, perspective drawing, mechanics and statics, etc.—that are not progressive, and even in regard to subjects on which we have added experience the amount of useful knowledge summed up in this book is more than could be found in any other single publication. We imagine that the latest edition is out of print now; at all events we never hear it referred to. Yet this is a book quite beyond the scope of what is generally called a "dictionary" of architecture. The object of a dictionary is to give more or less condensed information on everything connected with architecture, including explanations of terms, short biographical notices of eminent architects, etc.; but such articles in a dictionary are in general necessarily short, and often serve not so much to give full information as to indicate where to look further. Gwilt aimed at something far more solid than this; he endeavoured, to use his own words, "to compress within the limits of one closely printed volume all the elementary knowledge indispensable to the student and amateur." He went, in fact, far beyond the limits of what any "amateur" in architecture would ever trouble his head about, and he was quite justified in the modest conclusion which he goes on to express—"he even ventures to indulge the belief that it will be found to contain information which the experienced professor may have overlooked." And certainly any architect of the present day who possessed in his own head all the knowledge that is summed up in Gwilt's bulky volume would be a rather exceptional person.

Joseph Gwilt, who was born in 1784, was the son of an architect, George Gwilt, who seems to have had a good position in his day; he was Surveyor to the County of Surrey, and built the warehouses at the West India Docks. The son, the author of the "Encyclopædia," was a man of somewhat remarkable and varied attainments. Not only did he possess a great deal of practical knowledge of architecture and building, he was a member of the Royal Astronomical Society, and was an accomplished musical amateur; he held concerts in his own house for the performance of classical chamber music, was commissioned to write the article "Music" for the "Encyclopædia Metropolitana," and at the Coronation of Queen Victoria was entrusted with the conducting of the choir. When a short biographical paper on him was read at the Institute of Architects shortly after his death, a member who was present stated that in

addition to the acquirements mentioned in the paper, he had first known Gwilt, fifty years before, as the author of a grammar of the Anglo-Saxon language. Gwilt does not appear to have carried out any buildings of importance; but he was architect to the Grocers' Company, and remodelled the interior of their hall, besides carrying out some additional buildings for them. He was a great traveller, and is said to have been a diligent sketcher when abroad. He was a Fellow of the Society of Antiquaries, to which he was elected in 1815. He died at his house at Henley-on-Thames in 1863.

As far as the existing evidence goes, Gwilt's interesting architecture seems to have been mainly in regard to its practical side, as building construction. His first publication, indeed, in 1818, consisted of notes on remarkable buildings in Italy, under the title "Notitia Architectonica Italiana," which is more on the architectural side of the subject. His next publication was one on "The Equilibrium of Arches demonstrated on mathematical principles," and he also published a treatise on "Sciography"; in later life, however, neither of these seems to have satisfied him, as he mentions in the preface of the "Encyclopædia" that in regard to the former subject he had adopted for this work the principles as expounded by Rondelet, considering them better than his own, and that in the "Encyclopædia" he had not made use of his own treatise on sciography, but had treated the subject afresh, "trusting that matured experience had enabled him to treat the subject in a form more likely to be extensively useful than that of treading in his former steps." "The Rudiments of Architecture," published in 1839, might be more correctly called perhaps "rudiments of construction," except for the fact that plates of the Orders are appended to it; otherwise it is a treatise on the principal problems of construction, a kind of Vitruvius on a small scale, the subjects being treated in a very concise manner.

In 1837, however, Gwilt published a short treatise of another kind, his only work which can be called purely æsthetic, on "Elements of Architectural Criticism," dedicated to Cockerell. It is to a great extent polemical, having evidently originated in a desire to reply to and confute certain published criticisms on architecture which he regarded as unsound and deficient in true knowledge of the subject. The writings which he was criticising are of no consequence now—they have passed into the limbo of forgetfulness; but some of the opinions in Gwilt's essay are of interest, considering the date at which it was written. He alludes to the high position taken by the French in architecture—the highest in Europe, in his opinion; and attributes this to the justice and impartiality with which their competitions are conducted; the habits of the people, which allow of many families living in one large building (no idea of houses in flats had yet dawned on London); and the thorough and severe course of studies prescribed; in France there was no chance for half-taught architects to get on by good luck or favouritism. In another place he goes into some criticisms on the conditions of architectural design in England:—

"The Orders have been the principal basis for the manipulations (as they may be called) of architectural composition. And as readiness in applying them seems to have been always one of the chief objects at which young architects have aimed—so much so that they scarcely seem to consider a design

worthy the epithet architectural without the display of a portico, or at least some half-dozen columns attached to a wall, to which they are generally more an incumbrance than an ornament—the facility of their application has often superseded all consideration of propriety. This, in some measure, has arisen from placing more reliance on pictorial effect than propriety."

This seems a very modern kind of criticism to have been written in 1837. Then he attacks what he regards as the unthinking idolatry of Greek architecture: "Had Rome really nothing to boast of? Are the extraordinary Gothic edifices of the Continent, and no less of this country, unprofitable specimens of design and execution?" A question which was to receive a very large answer before many more years after it was put. Of the contemporary German Classic work, at Munich and elsewhere, he had the poorest opinion: "The German school is neither Italian nor Greek, but a bad compound of both"; a rather harsh and hardly fair judgment on Schinkel and Klenze.

How much of his great book, which in its latest form consists of 1,393 small-print pages, and was not so very much smaller in its first edition, was his own personal work, one cannot very well say; but probably most of it was written by himself; though in some portions, as he admits in the case of the treatise on the structure and equilibrium of arches, he based it on the ideas of writers of acknowledged authority. A sentence in the preface gives his own view of the position:—

"Though, in form, the whole work pretends to originality, this pretension is not advanced for the whole of its substance. Not merely all that has long been known, but even the progressive discoveries and improvements of modern times, are usually founded on facts which themselves have little claim to novelty. As a fine art, architecture, though in its applications and changes inexhaustible, is in respect of first principles confined within certain limits; but the analysis of those principles and their relation to certain types have afforded some views of the subject which, it is believed, will be new even to those who have passed their lives in the study of the art."

At all events Gwilt marshalled his vast materials in the most masterly manner; and it is evident that where he sought for outside help he took care that it should be of the best. There could not be a better illustration of this than in the series of small outline drawings of the human figure in various moments of action, which are introduced as illustrations in the section on "Drawing." It is not likely that Gwilt drew these himself; but whoever did them was a master of figure-drawing. The same spirit of completeness and excellence runs through the whole book. Except in regard to subjects on which the information of his period is necessarily out of date now, we do not believe there is a book of information on architecture more absolutely reliable than Gwilt, or more full in its information on the science of construction. With the exception just mentioned, of the out-of-date subjects, one never looks into Gwilt in vain; whatever one has a right to expect from a publication of that date is sure to be there.

The "Encyclopædia" commences with a very well-written history of architecture, filling more than 260 crowded pages of small print, and though the small woodcut illustrations would be thought unsatisfactory now, they are very well selected. Probably, from references to works more recent than the original edition, this history was to some extent amplified by the later editor, Wyatt Papworth, also a very careful and conscientious writer as to facts. Some of the views expressed, especially as to the development of early Gothic and its relation to preceding styles, would not be accepted now; but as a whole the History is a wonderfully good summary for the time at which it was written. After this we come on the real business of the book, "The Theory of Architecture," forming Book II., and commencing with Geometry, Plane Trigonometry, Conic Sections, and "Descriptive Geometry," using the term to express "that part of geometry which consists in the application of geometrical rules to the representation

of the figures and the various relations of the forms of bodies," which includes, of course, projection and the principles which underlie stereotomy, though the latter subject is much more fully developed under the head of "Masonry Construction." Mechanics and Statics occupy a long section, followed by the application of all these subjects in the structure and equilibrium of piers and vaults. All these practical sections are not mere outlines; the subjects are gone into very fully, illustrated with numbers of diagrams. "Walls and piers" and "beams and pillars" follow. There follow after these long treatises on materials. Perspective is very fully and completely treated. Then we come to what every instruction book of the period had to include (and should still include), a complete analysis and illustration of the Orders, prefaced by a short chapter on "Beauty in Architecture," which includes some really good and weighty considerations, as worth attention now as the day they were written. We will quote the list of maxims by which the student is advised to test the quality of his design:—

"1.—Let that which is the stronger part always bear the weaker.

"2.—Let solidity be always real, not brought to appear so by artifice.

"3.—Let nothing be introduced into a composition whose presence is not justified by necessity.

"4.—Let unity and variety be so used as not to destroy each other.

"5.—Let nothing be introduced that is not subordinate to the whole.

"6.—Let symmetry and regularity so reign as to combine with order and solidity.

"7.—Let the proportions be of the simplest sort.

"8.—Let him recollect that nothing is beautiful that has not some good and useful end."

Nos. 4 and 6 are perhaps rather vague; but the rest of the maxims are surely admirable.

The "Principles of Proportion" forms a very long section, a book in itself, and the theories as to the rules of proportion possibly applied in Classic buildings are, to our thinking, of rather doubtful utility; the author is not (any more than any one else) able to make the diagrams of proportion exactly fit the facts; but he does not insist on them too dogmatically, and there is a great deal in the treatise which is at all events suggestive, and leads the reader to think about the reasons of things.

To the book is added a list of architects from the earliest times down to the nineteenth century, with brief notices of their works, and a glossary of terms used in architecture and building; this is of great length and very fully carried out, and forms the conclusion of the work.

In a word, Gwilt's "Encyclopædia" is a monumental book, one of the most remarkable publications in connection with architecture in the English language, and ought not to be forgotten. It would be well worth while to produce, under competent hands, another new edition, bringing up again to date those portions of the book which require it, and adding what is necessary in respect of methods of construction which have come into use since the last edition.

It might be better in that case to divide it into two volumes, as it is already rather inconveniently bulky. But it is too remarkable a book to be allowed to die out and be forgotten.

The Proposed Lambeth Bridge.

IT is satisfactory, so far, to find that on Thursday last the House of Commons rejected the second reading of the Lambeth Bridge Bill by 180 to 115. Mr. Essex, who moved the rejection of the Bill, did so in order to elicit further information as to the bridge, which would be within view from the Terrace of the House, and he did not think that for £240,000 they could get a bridge worthy of the site. The fact that the bridge would be seen from the Terrace is not the most important point, though no doubt proximity to the seat of legislature is an additional reason

for consulting architectural dignity in a public structure ; but in the opinion that nothing worthy of the occasion could be done for £240,000, he was absolutely correct. Mr. Crooks, who seconded the rejection, deprecated the mistake of "belittling London," and one may be glad to observe that a feeling in favour of architectural dignity as against false economy is gradually beginning to pervade the House of Commons ; we have waited long enough for it. The fact seems to be that because the existing Lambeth Bridge was built only as a kind of extra bridge, of no great importance at the time, therefore the new bridge can be treated in the same way, as an unimportant and comparatively small bridge. This is a double mistake. In the first place, it is desirable that all the bridges over that part of the Thames which flows through London should be of architectural dignity and of a monumental character ; that they should carry the architecture of the city across the river. But in regard to the Lambeth Bridge there is the point to be considered, which the London County Council do not seem in the least to realise, that the Lambeth Bridge, if of adequate scale and structure, would furnish the shortest route from Victoria to the East End docks, more especially if the street plan on the Middlesex side were improved and a broad avenue opened from Victoria Station to the new bridge. That would be one of the greatest public improvements in south-west London ; it is likely to be carried out sooner or later, and the Lambeth Bridge ought to be ready for it, and to be planned accordingly. We were rather disappointed with the speech of Mr. John Burns on the occasion ; he urged, indeed, that a wider bridge than that proposed would probably be needed, but he said nothing as to the desirability of a fine bridge from the architectural point of view. Mr. Burns has so often given evidence of his sympathy with schemes for increasing the architectural beauty and dignity of London, that one must regret that in discussing the Lambeth Bridge Bill he did not take the opportunity of pressing this consideration on Parliament, but contented himself with a merely utilitarian speech.

The Institute Meeting-Room.

A SUGGESTION which was made by Mr. Munby, in the *Institute Journal*, for rearranging the seats in the room in which the Institute meetings are held, was put on trial at the last meeting. It is unfortunate that the meeting-room is too long and narrow to fulfil the best conditions of a meeting-room ; that was unavoidable—the room was there, and had to be taken as it was. There has been some complaint that speakers at the farther end of the room could not hear those in front well. The alteration has been to move the President's desk to the centre of one of the long sides, and arrange the room with the benches in the centre portion parallel with the longer wall, and those towards each end put slanting across the room, so that those at each end face towards the presidential chair. For the general discussions at a business meeting this is an improvement ; for meetings for the reading of papers we do not think it is ; the reader of the paper cannot act the part of Mr. Facing-both-Ways in the "Pilgrim's Progress," and can only face and speak towards a portion of his audience. It is much better, in the reading of a paper, that all the audience should face the reader, and there is no difficulty in those at the farther end of the room hearing, if a lecturer reads clearly and not too fast. And for lectures illustrated by a lantern the side position of the screen would be fatal ; the lantern could not be got far enough off to set the most effective focus, and only half the audience could see the illustrations properly even then. For lantern illustrations it is absolutely necessary to have the screen at the end of the room and the audience facing it. The next paper, by Mr. Ward, on the Architecture of the French Renaissance, will probably be accompanied by many interesting illustrations, and for that we hope the old arrangement of the room will be returned to. The best decision will be, in fact, to retain the

old arrangement for all reading of papers, and to adopt the side position of the chair only for business evenings when there is a general discussion and no formal paper is read.

The Front of the Institute Premises.

IT is a great pity that the front of the house in Conduit Street, which is in itself a perfectly harmless façade of the old conventional type, and is not at all in bad taste, should continue to be defaced by the ugly and commonplace cast-iron railings in front of it. All the metal details inside the building have been re-designed in excellent taste ; only on the outside, where every one can see it, this piece of bad Victorian ornamental railing has been retained, representing the worst form of inartistic metal-work. The Institute really ought, for its own credit, to commission Mr. Hare, who was architect for the alterations,¹ to make a good if simple design for a new front railing. The alteration would make all the difference in the general character of the front of the Institute house.

The Art of the Etcher.

THE special type of artistic expression which can be attained by the use of the etching-needle could hardly receive better exposition than in the present (the thirtieth) exhibition of the Society of Painter-Etchers, opened this week at the rooms of the Society of Water-colours. It is one of the best exhibitions they have ever had, full of beautiful work all round the walls ; and we are glad to see that there is an increasing tendency to depend on the genuine character of etching, that of work in free line, and less and less on those rather *ad captandum* effects in aquatint of which we used to see so many. Sir F. Short, our greatest master of true etching in line, has indeed deserted his colours this year, for the employment of aquatint, in which he has produced some charming effects ; unfortunately he only exhibits three works. We hope he will return to the art of which he is such a master ; the art of showing how much can be conveyed in a few lines.

Among the large number of the exhibitors who keep to line work there may be said to be two divisions : those who draw with a careful use of line shading which might be imitated by the pen, and those who rejoice in the freedom of the etched line without attempting to define things too precisely. The first style is the prose, the second the poetry, of etching ; though there is some excellent and interesting work in the prose style. There are those, again, who carry freedom of line too far, and give us work covered with a scrawly, untidy mass of lines which have no definite meaning. It is of the essence of etching to get an effect with few lines and much untouched surface ; the important point is to know when to leave off. Mr. Bernard Eyre's etchings are good examples of this class of work, and Mr. Gaskell's "The Mouth of the Wye," Mr. Charlton's "The Winding Road," and many others that might be mentioned. It may be thought an easy art to leave the whole mass of water in a river scene as untouched paper, and let one boat make a dark spot in the middle of it ; but it is a treatment which speaks the character of etching ; and the point is, to know just where to put your boat. On the other hand, Mr. Haig's "Neidpath Castle" is what we should call engraving, not etching.

There are a great many architectural subjects. M. Simon has managed to get a powerful effect out of the interior of Notre Dame with the light coming through the rose window ; an effect only to be obtained by a very careful and laborious working up of the darkened interior ; but there is nothing stiff or mechanical about it. Miss Hughes has not been quite successful with "The Old Houses of Parliament, Dublin," because Classic architecture will not bear too much line shading ; it loses its precise and finished look, and requires a different kind of treatment. Mr. Schröder contributes an etching of "The Old Dee Bridge, Chester," the one the picturesque quality of which was mentioned

in the discussion on Mr. Waterhouse's recent paper on bridges. Mr. W. Monk may be congratulated on a fine and powerful etching, on a rather large scale, of Carnarvon Castle. There are many other examples of the treatment of architectural subjects in etching, which should be of interest to architects.

A collection of the etchings of the late Professor Legros, of whose art we have spoken recently, forms a special feature in the exhibition, and illustrates his powerful though rather sombre genius.

Méryon's Etchings of Paris.

THE foregoing consideration of etching leads us to notice the excellent reproductions of eight etchings of Paris by Charles Méryon which form a prominent feature in the March issue of "The Architectural Review." Méryon was the greatest of all French etchers, and the plates which he produced during his short tragic life are the finest work of their kind since Rembrandt laid down his needle. To quote the writer of the matter accompanying the reproductions in question: "For Méryon art was not a flower-bordered path, but one overgrown with the wild tangled weeds of melancholy and madness—he died in 1868 in the madhouse at Charenton. What wonder, then, if his etchings should tell of this! Certainly stone walls never took on a more terrible physiognomy than under his touch. There is perhaps nothing more poignant in art than some of his etchings; despair seems to lurk in the streets, and madness peeps forth from the windows. R. L. Stevenson said of Paris, 'Certain old houses demand to be haunted.' Surely no one was fitter to portray this aspect than Méryon. His etchings were made merely to supply views of a Paris which was rapidly disappearing, and although he saw it all with eyes behind which an indefinable sorrow was hidden, yet his portrayal was accurate. No artist, indeed, was ever gifted with a more accurate needle to delineate architecture. His line is a marvel of strength and decision, often emphasised by the severity adopted in the treatment of his subject, yet is never lost sight of in his more intricate compositions. 'L'Abside de Notre Dame' is perhaps his greatest etching, 'by right of its peculiarly majestic composition and of its solemn and austere beauty.' . . . Seymour Haden, writing of 'L'Abside' and 'La Morgue,' says: 'From both of these it may be inferred that his work was not impulsive and spontaneous, like etched work in general, but reflective and constructive, slow and laborious.' . . . His method was this—he made, not a sketch, but a number of sketches, two or three inches square, of parts of his picture, which he then put together and arranged into an harmonious whole, which whole he first bit in (with the acid) and then worked into completeness with the dry-point. What is singular, and a proof of his concentrativeness, is that the result has none of the artificial character usual to this kind of treatment, but that it is always broad and simple, and that the poetic motive is never lost sight of. There is a trial-proof of "Le Stryge" in the British Museum which throws an interesting side-light on his methods. Where it is etched the plate is practically carried to completion, but the chief features of the composition—"Le Stryge" and the Tour St. Jacques—are not even suggested; the paper is blank where they are to come.' . . . Méryon's whole output amounted to about 100 plates, many of which are chiefly interesting as being by his hand, but the Paris set makes his sufficient monument. These were something new, a new aspect of architecture which the world had never seen before."

Other articles in the March issue of the "Review" include—Chambers and Myers at Trinity College, Dublin, by Mr. Harry Sirr, F.R.I.B.A.; William of Wykeham as a Castle Builder (with a newly discovered plan of Queenborough Castle), by Mr. Alfred W. Clapham; An Unpublished Sketch by Elmes of St. George's Hall, Liverpool, by Mr. C. Harrison Townsend, F.R.I.B.A.; Some Suggestions with regard to London Traffic, by Mr. W. L. Lucas; and Book-plates, by Mr. G. S. Powell. The "Practical Exemplar" is devoted to the Hôtel des Sociétés Savantes at Rouen, while "Current Architecture" is

represented by a large number of special photographs of Whiteley's new premises, the architects of which are Messrs. John Belcher, R.A., and J. J. Joass, F.R.I.B.A.

Pompeian Ornament.

THERE is a great deal of charm in the painted ornaments on the walls of the unearthed houses of Pompeii, with the general character of which we are all more or less familiar; but attention is called to them afresh by the issue of an attractive volume of coloured prints, accompanied by a short essay in which the varieties of style are briefly analysed.* The special value of this publication is that, by the use of the three-colour process of printing in colours, it has been possible for the first time to give what are claimed to be facsimile reproductions of the actual effect of the decorations. Owen Jones included some coloured plates of Pompeian work in his "Grammar of Ornament," but these were probably rather an approach to the original effects than a reproduction of them.

It must always be remembered that Pompeii was a place to some extent of Greek traditions in art, having commenced its existence as a Greek colony, and having still in it the remains of a sixth-century Greek Doric temple; and though the place only became important at a later date, and under Roman rule, one may imagine that its Greek origin left its mark on the taste of the city. Some of the details figured are Roman enough, but the style of decoration with which we are most familiar as Pompeian has a character of its own, not quite similar to anything else that is known in antique work.

Mr. Briggs, the author of the work, adopts Mau's classification of Pompeian decoration into four styles, succeeding each other chronologically, and distinguished as "The Incrustation Style," "The Architectural Style," "The Ornate Style," and "The Intricate Style." The nomenclature is rather clumsy, but it will serve. What is called the "Incrustation" style really means the use of mosaic as a decorative surface, the first illustration being that of a column which was covered with mosaic decoration, parts of which are given in colour in detail. The whole effect must have been very rich originally, though some of the ornament is too naturalistic for mosaic. Two wall fountains between columns show a very elaborate decoration with mosaic, partly in coloured panels, partly in naturalistic ornament. A stucco ceiling to the Stabian Baths introduces us to quite a different style of decoration, based on intersecting circles defined by different coloured bands. This would not be the least recognised as Pompeian, according to the popular knowledge of Pompeian decoration; it looks in fact remarkably modern. It is when we come to the "Ornate" style that we recognise what we generally know as Pompeian ornament; friezes formed of thin light festoons depending from painted horizontal stems (they are too thin to be called poles); birds, sprigs of flowers, and sometimes artificial objects, being introduced to fill in the scheme. These are painted in fresco on a plaster surface. They form an exceedingly pretty kind of ball-room or boudoir decoration, but not what can be called a very high type of art; it is work that can be lightly conceived and lightly executed, with a great deal of rather superficial grace. What is called the "Intricate" style is less spontaneous, and more crowded with detail—variously coloured panels, some with figures or groups painted in them. Some of those that are given are rather overloaded with detail, and do not show the easy and spontaneous grace of the preceding style. The best things that are familiar to us as Pompeian decoration, the panels with one little dancing figure, often of exquisite grace, painted in the middle of the panel, do not appear among the illustrations.

The Greek spirit which existed at Pompeii is most shown in some of the uncoloured illustrations of work of a more architectural kind, especially the white marble table support which appears in the third plate, consisting of two winged griffins back to back, the space between them filled

*Pompeian Decorations. By R. A. Briggs, Architect; Soane Medallist and Fellow of the Royal Institute of British Architects. London: E. & Batsford. 25s.

in with carefully designed scroll-work which is quite Greek in feeling. This is still *in situ* in the Impluvium of one of the houses; it has, we think, been often illustrated, perhaps not so well as here. Another interesting piece of architectural work is that shown in the last plate but one; a seat recess arched over and with a pediment above. The recess is flanked by fluted pilasters with no bases, and carved capitals from which the arch springs; upon these stand two narrower pilasters also without bases, and not central with the lower ones; which looks rather awkward, but the details generally are good and refined. It would have been more convenient if the plates had been numbered for reference.

The author thinks there is likely to be a taste for the type of Pompeian decoration, seeing that "the trend of architectural thought is now towards the Græco-Roman style," and the designs illustrated have been selected as likely to be useful to architects as sources of inspiration; some of them may no doubt serve that purpose. In any case, a beautiful book has been produced, which many besides architects may be glad to possess. The remarks at the end of the preface are somewhat exaggerated. To say that the style "overwhelms us by its invention, fecundity of expression," etc., and that "the inspiration of these decorations is infinite, and the language in which they speak is everlasting," is a little too exuberant a description of work of which facile charm is the chief characteristic. Superlatives should be kept for things superlative.

American Architectural Omniscience.

A RECENT issue of the "American Architect" contains a leading article in very large type containing the statement on the part of Professor Goodyear, 'Curator of the Department of Fine Arts, Museum of the Brooklyn Institute,' that another American architect, Mr. A. K. Porter, has made "the most important contribution to the topic of mediæval construction which has been published for many years." Those who are aware of the tendency of writers in American magazines to blow the trumpet continually for the art and artistic productions of their own country will probably be of opinion that a declaration by one American architect that another has made a most important discovery about Gothic architecture is a kind of statement to be taken with a good many grains of salt. The whole of this wonderful discovery seems to amount, first, to a statement that rib vaulting was brought into use to simplify the building of vaults without solid centering, the ribs being built on separate centre pieces. As far as we are aware, no one in his senses ever thought otherwise. Secondly, that the Lombard Italians practised it before the French, and therefore that they are the inventors of Gothic architecture. The statement that the Italians built these early vaults without solid centering is a mere assertion on the part of Mr. Porter, who did not see them built, and has no ground for the statement whatever beyond his mere assertion. Mr. Porter, in a history of Gothic architecture in which (after the fashion of American writers) he entirely ignored the existence of English Gothic as not worth taking into account, asserted that the pointed arch seemed in the transitional period to be used from mere caprice, giving as proof of this an example (Pontorson) in which only a large arch carrying a great superincumbent weight is pointed, and all the small decorative arches are round; that is to say, the constructive reason for using the pointed arch stared him in the face, and he could not see it. After that, we really cannot accept him as a witness capable of drawing sound deductions from the observation of ancient buildings. The fact that the pointed arch was first used for arches which had to carry great weight, while the round arch was retained for the smaller openings in the same structure, has been familiar to English students ever since Sharpe's "Parallels" was published sixty years ago; the Americans, who adopt such an attitude of superiority as teachers of architectural history, have apparently not discovered it yet. As to whether some Italian builders

used groined vaults before the French did is a matter of little importance in the history of Gothic; the French made a consistent style of it, and the Italians did not. Professor Goodyear's elaborate efforts to prove what must be obvious to anybody with structural common sense—that in a ribbed vault the ribs must have been built on separate wooden supports and the spaces filled in afterwards between them—are really amusing. He gives a photograph of the vault at Soissons, and proceeds to point out the change from large stones in the lower portion of the ribs to small ones above, and that the small ones mark where the centering began. Of course they do; the lower portions are where the ribs are worked on stones tailed into the wall, what in French is called the *tas de charge*; every one knows that who knows anything about Gothic at all. In a note to this illustration we are informed that above the *tas de charge* "the courses are made narrower in order to diminish the weight resting on the *cerce*" (Viollet-le-Duc's name for the centering template on which the groin was built). Whether this note to the illustration is Mr. Porter's or Professor Goodyear's is not apparent; the supposition seems to be that if the rib is built of a great number of small stones the total weight of the stonework is less than if it were built of fewer and larger stones! It seems almost puerile to explain that until the rib is completed as an arch up to the crown of the vault, the combined weight of its voussoirs comes on the centering with just the same weight, whether it is built of small stones or large. The whole article, in its absurd trumpeting of a great American architectural discovery, seems worthy of the Professor who has gone about Europe measuring all the failures and settlements of walls and vaults in ancient buildings, and endeavouring to persuade the world that these dilapidations are "refinements" of architectural design. It may seem rather harsh to speak in this tone, but really the absurd attitude of superiority assumed by American writers on architecture about things which we know far more about than they do does provoke one to a little plain speaking.

Responsibility for Defective Materials.

WITH regard to legal responsibility for dry rot, Mr. J. Davidson, secretary of the Yorkshire Federation of Building Trades Employers, has communicated to that body a brief but interesting note on a decision that has been recently recorded in the French courts. Two cases, of nearly identical character, were remitted, the one from Lyons, and the other from Rennes, to the Court of Cassation; but while the principle involved was the same in each case, the respective decisions upon it in the lower courts were at variance. In each case timber supplied by the contractor, according to a schedule of prices, and employed by him in building a house, became in a short time infested with dry rot. In each case it was shown that at the time when the timber was put in the contractor could not have known that it had in it the germs of this disease. The Lyons Court refused, and the Rennes Court agreed, to grant the owner damages against the contractor. In the Court of Cassation of the Seine the Lyons decision was upheld, and that of Rennes reversed. Upon this Mr. Davidson comments that the principle is therefore established in France that a building contract is not one of sale (in which case the contractor would be responsible for the materials he employed), but one of service. This view, while logical enough, is—perhaps for that very reason—hardly likely to find much favour in this country, where the consideration that overrides all others is that the owner who pays for a sound building ought to get it, and that if he does not get it, the man to whom he pays the money—the builder—or, alternatively, the man whom he pays to look after his interests—the architect—shall recompense him. No matter who suffers, or how unjustly, the building owner is to take no risks, and must be given his full pennyworth though the skies fall.

It is, of course, quite right that he should always get what he bargains for—his money's worth—when that is possible; but is it so very clear that, in case of an occurrence

for which, strictly speaking, nobody can justly be held responsible, such as an inexplicable outbreak of dry rot, the architect or the builder should incur all the resultant loss? Our law appears to assume that the architect and the builder ought always to be able to prevent dry rot, and should be made to suffer for any failure in this respect. The French law seems to recognise—what is possibly the fact—that occasionally the disease may be beyond foresight or prevention; and that in such circumstances the builder should not be burdened with the loss—that in fact he is not selling materials for whose soundness he is guarantor, but is procuring and using them on behalf of the building owner. This is perhaps a dangerous doctrine to set up, since it is perfectly obvious that advantage might occasionally be taken of it by unscrupulous traders, against whom the building owner is entitled to protection. Still, the judicial view of the subject in this country seems to be too stringently and persistently one-sided; the decisions nearly always giving one the impression of what, in the present state of knowledge or ignorance of the subject, seems to be a rather gratuitous assumption that dry rot can and ought in every case to be prevented; whereas the French Courts, upon what grounds we should very much like to be more fully informed, seem to have seen reason for holding that in some instances the disease is so insidious as to baffle skill and foresight. But the principle involved in the French decision is obviously larger than the question of responsibility for dry rot, since it affirms, as Mr. Davidson has pointed out, that a building contract is not one of sale, but one of service, and that therefore the builder is not responsible for defects that may develop in any material that he employs in the building owner's behalf. This may be an excellent theory, but it would be worse than folly to encourage any hope that it is ever likely to find acceptance in this country; where, however, the point is of some ethical and dialectic value, even though it may not directly affect practical issues.

The Question of Contractual Referees.

ONCE again the Courts have lent support to the contention that, as a general rule, it is undesirable for a corporation official to act as arbitrator in a serious dispute to which his employers are parties. This view has just been upheld by the Court of Appeal, consisting of Lords Justices Vaughan Williams, Farwell, and Kennedy, in an appeal by the Corporation of Bristol against an order by Master Macdonell, which had been affirmed by Mr. Justice Scrutton in Chambers, refusing to stay the action in which Messrs. John Aird and Co. sought to recover £171,215, balance on a contract sum stated at £1,927,977, for work, etc., for dock works at Avonmouth. The corporation contended that by the terms of the contract the matters in dispute should be referred to the arbitration of the corporation engineer. This contention raised a point that is only too familiar, and that, in several recent cases, has been determined in favour of those who held to the contrary. In the appeal under notice, counsel for the corporation cited decisions in which, on the other hand, it had been laid down "that there was no valid objection whatever to the enforcement of an arbitration clause making the engineer arbitrator in matters in regard to which he had himself played a very considerable part," and he argued that the advantages of making the engineer arbitrator were obvious—that his familiarity with all matters relating to the contract would prevent the expense of establishing the facts

before a gentleman who was not cognisant of the matters in dispute; and that there was no legal objection to the engineer acting as arbitrator because in his certificates he had taken views which, as arbitrator, he would be called upon to review. This contention did not prevail, the Appeal Court upholding two former orders declining to stay the action. Although, as we have said, this judgment confirms several others to the same effect, it must not be regarded as final, conclusive, and generally comprehensive. Similar cases that arise hereafter will no doubt be dealt with, as the present and all the precedent cases seem to have been, purely on their material merits, and judges may in future see sufficient reason to vary their decisions in accordance with specific circumstances. It would be very rash to assume from recent decisions that the very important question as to whether or not an architect or an engineer, being in effect a party to the contract, is *ipso facto* disqualified from acting as arbitrator in cases of dispute on points that arise in carrying out that contract, has been decisively answered in the negative. The controversy on the subject is not yet closed, and is still likely to be a fruitful cause of litigation, until contractors finally agree to support each other in insisting on provision being made for disputes of sufficient magnitude to be referred to independent arbitration. This condition casts no slur on the honour of architect or engineer; it simply recognises that, being human, he ought not to be placed in the invidious position of arbitrator between himself and another man: which is what, in its essence, the arrangement comes to. The objection to the contractual arbitrator may be said to work both ways. As it is commonly the arbitrator's own views that are in dispute, it is only rational to suppose that the average natural man will find it extremely difficult to avoid deciding in his own favour. On the other hand, the man with an uncommonly delicate sense of honour may, with "the pride that apes humility," think it more decorous to give the other side the benefit of the doubt. In either case, approximation to the proper judicial attitude is less evident than near approach to solemn farce. Nor should it be overlooked that the question of contractual referees is one that concerns engineers much more closely and with much more frequency than it affects architects; the work of the latter offering comparatively rare occasions of sharp contention, while it usually involves infinitely smaller sums. Most of the legal actions in which this question of contractual referees has arisen have referred to large engineering contracts; and the position of the architect is in so many respects different from that of the engineer as to deserve separate consideration; for it is very clear that if the architects' decisions were made liable to dispute and reference in detail at every turn, his authority, if not his occupation, would be gone, and his position would become perfectly intolerable.

FIG. 3.—ANTHEMION AND ACANTHUS FROM FRIEZE OF ERECHTHEUM.

THE GREEK ACANTHUS.

THE endeavour to establish the precise origins of certain forms in Grecian architecture has been largely without result, or at least the evidence which has been brought forward in support of some of the theories has been based on supposition rather than fact; hence, while a few things have been determined incontrovertibly—like the curvatures adopted to correct optical illusions, established by Penrose's measurements—many other matters have not advanced very much towards solution. Nevertheless, the pursuit is an interesting one, and not without profit. This is the case with the Corinthian capital and its acanthus enrichment. The familiar story, or rather legend, is that Callimachus the sculptor saw on a grave at Corinth a basket surrounded by acanthus leaves; the chance arrangement struck him, and he perpetuated it in the leaf-surrounded bell of the Corinthian capital. This account has been generally and somewhat uncritically accepted, and the belief is equally prevalent that the plant he saw and imitated was the *Acanthus spinosus* of Linnaeus. So general is this belief that travellers with Classic inclinations have sought the plant near Corinth, though fruitlessly. The term "Corinthian," as applied to an architectural style, has no contemporary Greek authority, but, accepting the name as generally understood, the Corinthian is not the earliest in which acanthus foliage is used; a misconception at this point is due to belief in the story outlined above.

FIG. 1.—STELA IN THE BRITISH MUSEUM.

the endeavour to determine what in nature was the origin of the ornament, and to trace its evolution in art, the appeal must be to actual remains of early Greek sculpture. Mr. A. H. Smith, in his "Catalogue of Greek Sculpture" of the British Museum, gives it as his opinion that the use of the acanthus leaf, as an ornament, was introduced at some time in the fifth century B.C., perhaps from Ionia, and it very soon became a very favourite ornament for stelæ in Athens. The British Museum possesses many examples of these stelæ; that shown by Fig. 1 is typical, and a general description of it may suffice for reference. The surface is smooth, and the triangular apex is filled with an anthemion (perhaps it is even advisable to add its pseudonym "honeysuckle ornament"). This springs from the centre of five acanthus leaves, which may be said to grow from the basal cutting off the acroterion of the stelæ; it is a representation on a flat surface, and in low relief, of a rosette of leaves seen from one side, spreading on the ground, the outer leaves touching it with their reflexed tips; the centre of the group, owing to this turning-back, presents to the observer part of the upper surface of the leaf, while the side leaves are seen in profile; the base and tip, as it were, are pressing the earth (see Fig. 2). The three lowest leaves thus grouped appear unchanged through a large number of examples.

FIG. 2.—ACROTERION OF STELE OF SMIKYLION.

It may be conjectured that the ornament was used on stelæ before it was employed for the decoration of buildings. The Erechtheum supplies an early date for this stage in its development, the temple being Ionic, and the date of its completion known to be about B.C. 409. The anthemion and acanthus ornament of the frieze (Fig. 3) is very familiar. It was the most beautiful combination of natural leaves with the conventional flower.

In this form also it decorates the necking of a column; the leaves are so small in proportion to the anthemion that they are adapted to the round surface without any alteration. Development is not carried on in this direction, for the anthemion falls away, and its place is filled by various tentative methods, until the acanthus fills the whole space. Examples are the lance-shaped leaves of the capital on the Tower of the Winds (Fig. 4) and the scrolls in the pilaster capitals from the Temple of Athene Polias at Priene—to be mentioned later.

Before dismissing the Erechtheum examples, it is not without interest to note that Callimachus's name is connected with the decoration, Pausanias (IX., 2, 7) telling us that a wonderful candelabrum was made for Athene there by the sculptor. The frequency of acanthus on funereal stelæ has a bearing on the story.

Another step on the way to the use of acanthus on bell capitals is that on the flat square sides of pilaster capitals; there are many examples of this in the Mausoleum Room at the British Museum. The typical stela arrangement, as shown in Fig. 1, is transferred direct to the square face of

FIG. 4.—CAPITAL OF COLUMN FROM THE TOWER OF THE WINDS, ATHENS.

FIG 5.—CAPITALS SCULPTURED ON A SLAB ON A CORINTHIAN TEMPLE (POSSIBLY THAT OF APOLLO AT DELPHI).

the capital, the familiar group of three acanthus leaves being arranged along the base, and the anthemion stretching over the upper space, which is obviously larger than in the stèle acroterion.

In early examples of acanthus on bell capitals, such as that from the Tower of the Winds, and the fragment of a relief showing the columns of a Corinthian temple in the background (Fig. 5), there is a reminiscence of the three-leaf arrangement; the leaves also cling about the necking; the upper two-thirds of the capital from the Tower of the Winds is filled with a circle of erect lance-shaped leaves, very similar to those on an Egyptian bell capital in the British Museum assigned to the date 1330 B.C. (Fig. 6).

These experiments, for as such we must regard them, in filling the space above the single tier, culminate in the adoption of an upper circle of the same leaves. The pictorial treatment suitable to a flat slab has to be abandoned, and the perfected form of the Corinthian capital is attained. The examples given will suffice to demonstrate that the use of acanthus foliage as an ornament was frequent in the Ionic style, and that its translation from flat to curved surfaces brought about the change from its early naturalistic treatment to the conventional acanthus of the Græco-Roman and Roman styles called "Corinthian."

Granted that the acanthus of the Attic stèle is naturalistic, the way is clear for the consideration of the question, What plant was the model? To turn Aristotle's phrase, it is "such a plant as might have grown." It may be described in botanical fashion somewhat as follows:—The leaves are close to the ground in a rosette, spreading horizontally; each leaf is broad to the base, oblong in general

FIG. 6.

outline, margin sinuate-toothed, the divisions reaching about one-third of the way to the midrib. Now, the same description would bring forward the salient points of a first year plant of one of the great biennial cotton thistles, may be seen from a photograph of *Onoporden acanthus* (Fig. 7). This plant and the nearly allied *Onoporden Illyricum*, *Græcum*, and *Arabicum* are characteristic of the Levant flora. Not any of these, however, but the *Acanthus spinosus* of Linnaeus is accepted generally as the original nature of the acanthus of art, perhaps because the former considered has been only the late development which naturalism has yielded to the requirements of the position.

Yet if likeness in line and grouping has any bearing on the question, *Acanthus spinosus* could not have been the origin of the acanthus of the stèle; it forms a prickly thicket of leaves; there is nothing to answer to the rosette-units of cotton thistles. Not only is the rosette arrangement

FIG. 7.—ONOPORDEN ACANTHUS.

is entirely wanting, but the shape of the individual leaves differs from the sculptured leaves on the stèle; the stalk is leafless, or very narrowly winged, and erect from the base; the narrow divisions of the blade fit between those of neighbouring leaves at all angles and levels, with no obvious apparent rule than that of intercepting all the light without overshadowing each other. A basket placed on leaves of *Acanthus spinosus* might as well, for artistic purposes, be balanced on a quick hedge; and even a legend must be consistent enough for probability.

FIG. 8.—ACANTHUS (NATURAL) FROM A DRAWING BY JOHN RUSKIN.

Greek references to the artistic acanthus by name are rare, and the few instances there are refer to small objects such as the goblet carved from ivy wood mentioned by Theocritus (Idyll I., 55). Ovid possibly derives from a Greek source his description of a mixing bowl, "Summus inaustr crater erat asper acantho." (Metam. XIII., 701). So in default of literary evidence, the main weight of the argument for identification must rest on actual likeness, and in this connection we have other leaves, such as those of parsley, celery, ranunculus, and many root leaves of baceous plants, which seem equally well fitted to have been the origin of the "acanthus ornament."

DESIGN FOR GUILDHALL (SOANE MEDAL)

COMPETITION). BY BERTRAM LISLE ("VISTA").

Front Elevation.

DESIGN FOR A GUILDHALL (SOANE MEDALLION COMPETITION). BY PIET DE JONG ("ANTÆ").

DESIGN FOR A GUILDHALL.

(See Centre Plate.)

We publish as a Centre Plate in this issue the design for a guildhall which was submitted by "Vista" (Mr. Bertram Lisle) in the recent competition for the Soane Medallion of the Royal Institute of British Architects. We have special interest in publishing this design, for the reason, already stated in these columns, that we consider it to be the best of those submitted in the competition. The Council of the Institute, while not considering any of the designs submitted to be worthy of the medallion, divided the £100 equally between "Circle City" and "Antæ," placing "Vista" third and awarding the author a certificate of Honorable Mention. The design of "Antæ" (Mr. Piet de Jong, of Leeds) is also illustrated in this issue. Mr. Horsley, in his criticism of the designs, said: "'Antæ's' plan is of the type of an *hotel de ville*, which would be quite suitable to the centre of a large town; but, on the other hand, the elevations, notably the facade adorned with caryatides, which give an unusual touch of gaiety to the design, are very appropriate to the open position proposed. The weak spot in the scheme is that the central guildhall is too small. . . . 'Vista' well deserves the Certificate of Honorable Mention which he has won. In my opinion his plan is the best in the competition. . . . The grouping of the

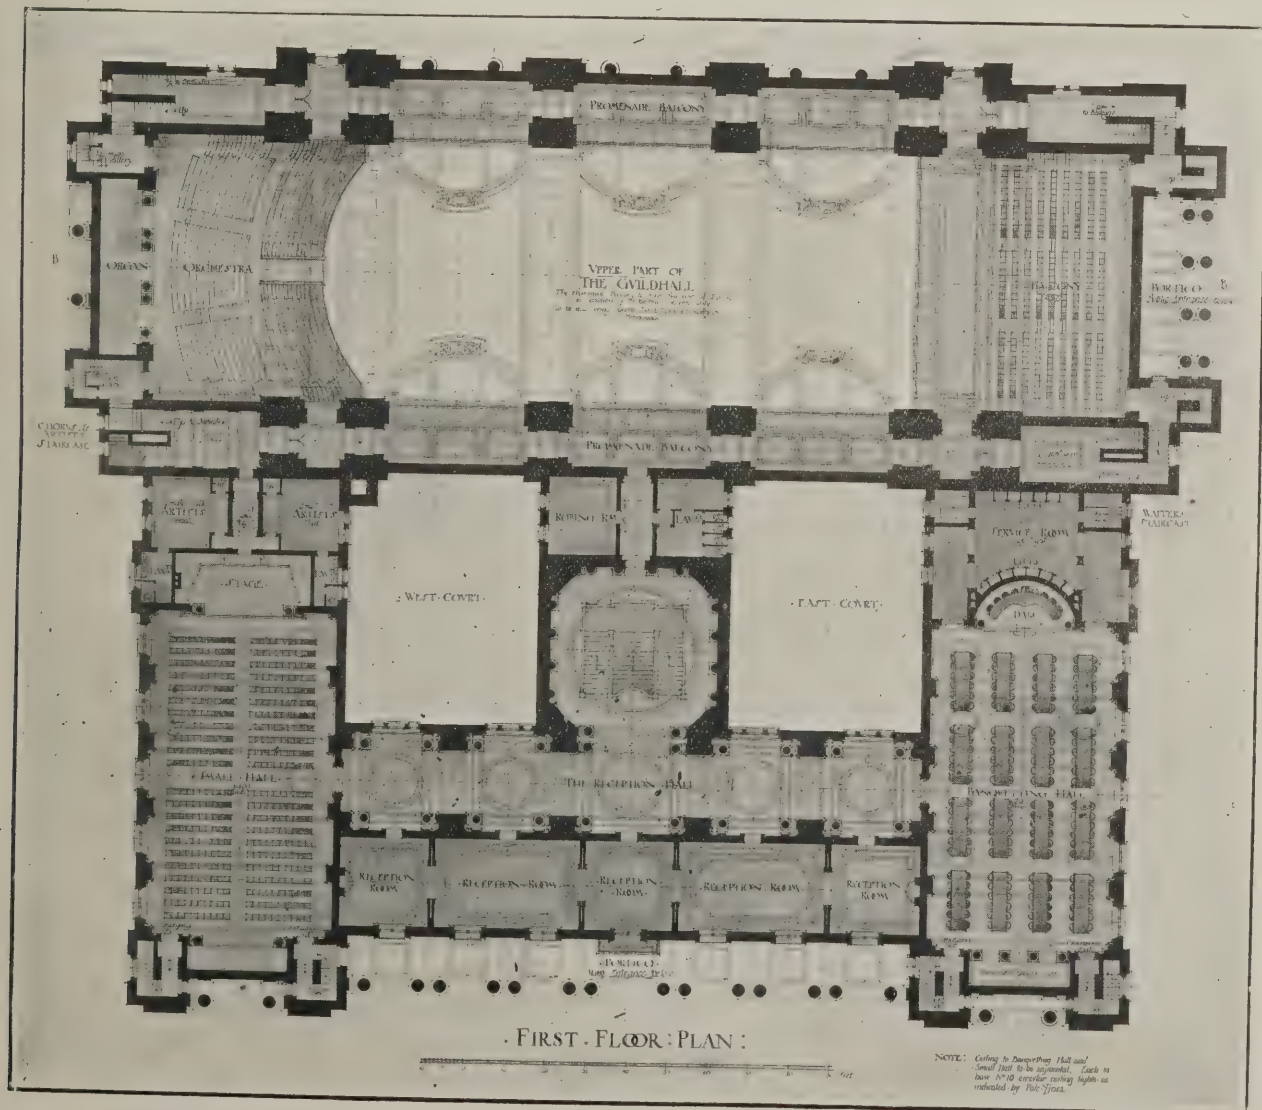

DESIGN FOR A GUILDHALL. BY PIET DE
JONG ("ANTÆ"): SKETCH PLAN OF
GROUND FLOOR.

reception rooms at the head of the principal staircase, between the banqueting hall and the small hall, on the first floor, is particularly happy. Again, the guildhall itself is admirably placed and excellently designed for its purpose.

NEW POLICE HEADQUARTERS FOR EDINBURGH.

The new headquarters of the Edinburgh City Police, with the new Court Room, and the Weights and Measures Offices, are to be erected on a site in the Grassmarket, Edinburgh. The frontage to the Grassmarket extends 203 ft., and the eligible building depth is 188 ft. As will be seen from the accompanying ground plan, the disposition of the ground permits of the administrative block facing the Grassmarket. Immediately in the rear is the court room block, and still farther in the rear is the cell block. Direct inter-communication is had with all three buildings. On a site the three sides of which have surrounding buildings, this arrangement permits of the premises being all favourably situated in respect of lighting, and secures a free play of air and through-draught to all parts of the buildings. Ample courtyards are also obtained.

The administrative block consists of four floors. As the Grassmarket is a wide open square, the external architecture demanded careful consideration consistent with the desire for stringent economy in the design of the whole buildings; and breadth of treatment and proportion are more relied upon than expensive repetition of details. The building material is stone, and it is suggested to have the ground-floor storey in a cream-coloured freestone, the upper

DESIGN FOR A GUILDHALL (SOANE MEDALLION COMPETITION). BY BERTRAM LISLE ("VISTA").

storeys being carried out in a combination of light freestone in the windows and other architectural features, and red sandstone in courses for the wall faces.

On the ground floor are the weights and measures offices, lost and found property office, charge office, with lieutenants', waiting, and witness rooms, etc. The first floor is allocated to the chief constable, including offices for the deputy-chief constable, chief constable's clerks, criminal investigation department, statistical department, etc. On the second floor are record rooms, police surgeon's office, procurator fiscal and clerk of courts' rooms, dwelling house for deputy chief constable, etc. The third floor is set apart for tailors' workshop and stores, dwelling-houses for chief housekeeper and lieutenant on duty, etc.

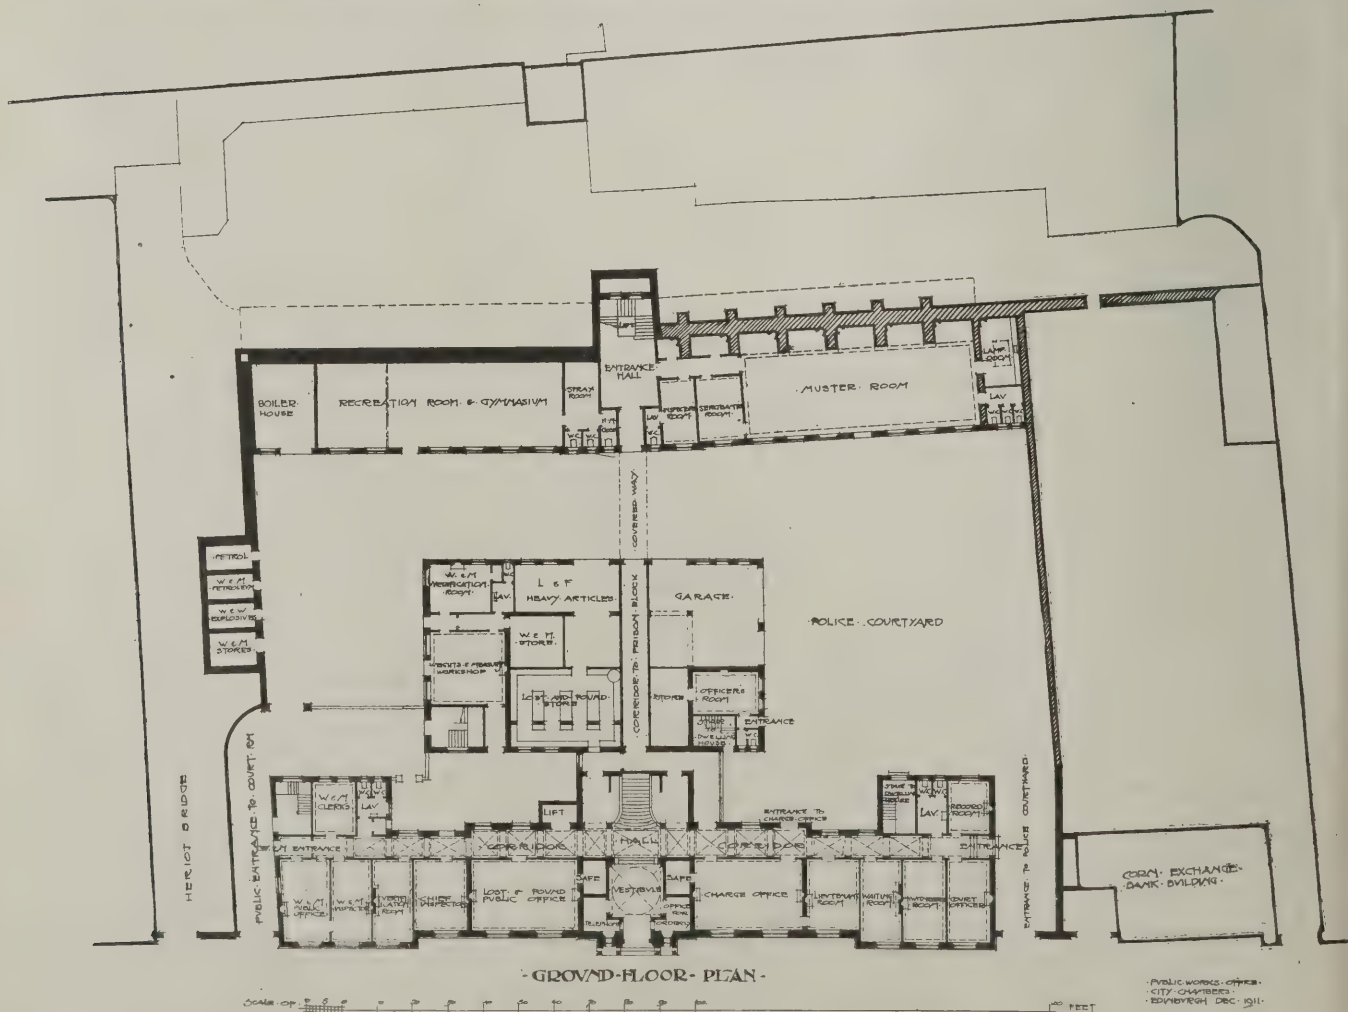

In the court room block, to ensure quietness, the court room is placed midway between first and second floors of the administrative block. The court room is accessible on three sides, one forming

a large waiting hall for witnesses, with solicitors' consultation room. Judges and other officials' retiring rooms are provided. The fourth side—that to the rear—is in direct communication by a bridge with the cell block, and has rooms for accused persons and court officers. The public, and witnesses, enter the buildings by a special stairway leading from the courtyard. In the substructure of the court-room block are two floors, devoted to various purposes, chiefly stores, but also comprehending a garage for police vehicles, and the dwelling-house of the officer in charge of the garage.

In the cell block there are 111 cells, namely: ordinary, 102; association, 3; and observation and examination cells, 6. The dimensions are: ordinary cells, 11 ft. by 7 ft. by 10 ft. high = 770 cubic feet each; association cells, 15 ft. by 9 ft. by 10 ft. high = 1,355 cubic feet each; observation cells, 11 ft. by 7 ft. by 10 ft. high = 770 cubic feet each. The ground floor contains the police-

muster room, gymnasium and recreation room, also lamp-cleaning room, and inspectors' and sergeants' rooms, storeroom, boiler-house, etc. In a central position is the entrance to the cells, and a landing conveys the prisoners to their respective landings. Two cell pavilions are placed right and left respectively of the staircase and contain turnkeys' and searchers' rooms, association and observation cells. The two upper floors of cells are reached from galleries having strong enclosed railings, the open wells being filled with open gratings, thus permitting light from a top cupola to penetrate to the separate levels, and allowing of a free passage of air throughout the cell block.

Mr. J. A. Williamson, A.R.I.B.A., city architect, has prepared the plan, and the estimated cost is apportioned as follows: Police headquarters section including painter work, heating, ventilation, and electric lighting—£43,750; weights and measures office section—£2,500.

NEW POLICE HEADQUARTERS AND WEIGHTS AND MEASURES OFFICE, EDINBURGH.

J. A. WILLIAMSON, A.R.I.B.A., CITY ARCHITECT.

OBITER DICTA.

In Praise of the Plumber.

He had often realised that if the principle underlying the constructional work of the plumber were better understood by the public generally they would be the better able to appreciate some of the many difficulties with which he had to contend, and, instead of bestowing upon him so much unwarranted abuse, they would look upon the plumber as a benefactor to his race in providing the conveniences and luxuries of home life, which was his rightful position.—*Mr. W. H. Allen, at Cardiff.*

Architecture and Colour.

It is quite certain that, where colour is used at all to decorate a building, it should be used systematically throughout. The effect of a series of mural paintings in a large interior otherwise uncoloured is merely to distract the eye from the whole interior to the patches of painting. Considered in their relation to that interior, they are, however excellent as pictures, mere irrelevant masses of colour, which usually conflict with the architectural effect of the whole. In fact, the finer the interior as architecture, the more irrelevant and distracting do mural paintings usually appear. There is a discord of two arts where there should be a harmony, or where one should reign alone. And yet whenever architecture has been the predominant art, it has nearly always used colour as an instrument of its own, whether in the form of paint or mosaic or stained glass. But in such cases the

decorator has been either the servant of the architect or subject to an architectural tradition which entirely controlled the practice of his own art. . . . The moral is that the architect should always be the master of his own house.—*"Times" leading article.*

Hills an Architectural Opportunity.

The fact is that bridges, viaducts, steps, and terraces are the making of a city from an æsthetic point of view. Any city, however, flat, like Manchester, can have fine streets if, like Manchester, it will pay for them; but few cities can have that combination of architecture and natural beauty which arises from a hilly situation. Rome, Edinburgh, Scarborough, and other hilly cities have contrived to use natural features to their advantage and to the never-ending delight of visitors, but Sheffield, with almost equal opportunities to some of these, has not yet, at least in its central area, tried to do this.—*Mr. H. L. Paterson, in a Sheffield newspaper.*

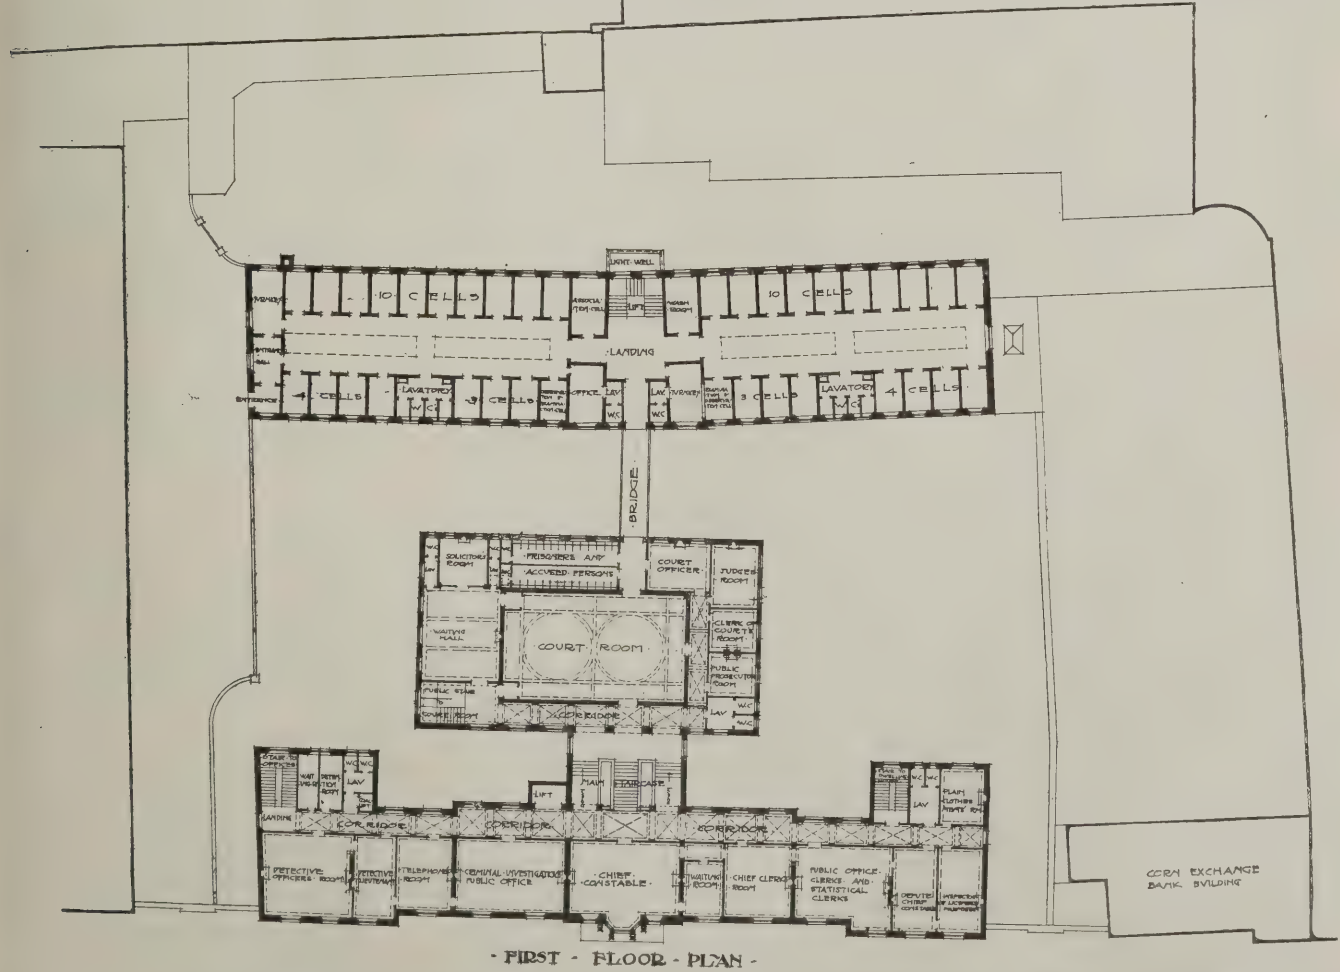

An Elastic Carpet for Roads.

Would it not be well to endeavour to provide an elastic skin or carpet to lie between the vehicle and the bearing crust? A material to be used for an elastic carpet for the road crust must have a viscous liquid quality. Research had been made with pitch and with bitumen, and the conclusion had been reached that pitch would not give satisfactory results, but bitumen would do so. It was expected that with such material laid on the top

of the main road crust and integrated with it a valuable road protection would be supplied, so that the road crust would be practically permanent, the upper protecting sheet being re-made up and re-laid as required. To fulfil the ideas of providing a partially elastic carpet, which would carry out the silencing of the rolling noise of vehicles and reducing shock, the engineers at the Road Board had already decided on experimental roads which would consist of a strong road crust intended to carry the weight of the traffic, and on this to superpose the renewable carpet.—*Sir John H. A. Macdonald, lecturing at the Royal Institution.*

The Architect's Potent Spell.

It may be fairly open to argument whether a great architect has not as much influence on the culture of his own age and the ages which follow it as a great poet or a great writer of fiction. The ballad-writer and the novelist have claimed for themselves in this matter of moulding the thoughts of men more power than the legislator. Possibly the architect may wield a more potent spell than either. The poet and the novelist may be as time goes on more praised than read. . . . The thoughts of men are turned into new channels, and every age demands expression of its emotions and convictions in its own way. But the work of the architect remains and cannot be ignored. We cannot put his books upon the shelf. For better, for worse, his buildings stand; they become part of our daily life, evoking admiration or

NEW POLICE HEADQUARTERS AND WEIGHTS AND MEASURES OFFICE, EDINBURGH.
J. A. WILLIAMSON, A.R.I.B.A., CITY ARCHITECT.

provoking maledictions every time we pass that way. Great is the responsibility of the architect and those who have given him his commission.—*Oxford Times*.

Modernism v. Authority in Architectural Design.

He entered a protest against the tendency in certain teaching of the day to stereotype the classical ideal in architecture, which was opposed to the flexibility and versatility of mind. He then spoke of the domination in France and Italy of classic design of the last two or three centuries, remarking that traditional mediæval architecture had been completely suppressed, and that the influence of the French schools of architecture in that direction had, in his opinion, been fatal to the more domestic, educational, and ecclesiastical architecture of the country, that side of practice which must occupy the majority of professional talent.—*Mr. Howard Seth Smith, before the Birmingham Architectural Association.*

Hard-headedness and Architectural Beauty.

They might take it that no passion possessed the public for beauty in building. They were a hard-headed, practical people. When he went into our manufacturing towns, or for that matter into any of our towns and cities, and saw what this practical hard-headedness had produced, he wished that they were soft-headed, soft-hearted, and unpractical. The way of architectural salvation would be a long and a hard one.—*Mr. J. S. Gibson, before the Glasgow Institute of Architects.*

The House Jobber Quack.

There are quacks in buildings as there are in medicine and everything else. The quack house jobber may be one of the many working jacks-of-all-trades, who professes to do anything. He usually poses as a "practical man," which generally means that he is utterly ignorant of all points of theory; he does no good—possibly makes matters worse—and charges well for it.—*Mr. Harold Griffiths, at the Auctioneers' Institute.*

Paint the Preservative.

The builder of the Tay Bridge was once asked how long his work would last. His reply was, "As long as it is painted." As a matter of fact, the bridge was being painted from year's end to year's end, and 500 tons of paint was used upon it annually. The preservative value of paint could not be over-estimated.—*Mr. Arthur Seymour Jennings, before the Bristol Society of Architects.*

Moral Sanitation.

In 1875 the great Public Health Act gave us the model building by-laws, and with them streets of monotonous cubicles for dwellings. In pulling down the old streets built before the Public Health Acts, we had obtained priceless benefits in the way of sanitation; but he [Prof. Adshead] was afraid we had lost almost as much in moral sanitation as we had gained in physical, and in applying the Town Planning Act and the new science of town improvement we had got to try to recover the beauty that was lost with the disappearance of those old streets, and, whilst continuing to improve our sanitation, to increase moral and æsthetic amenities at the same time.—*Prof. S. D. Adshead, at the Municipal School of Technology, Manchester.*

EARLY PRECAUTIONS AGAINST FIRE.

The early precautions against fire adopted by the City authorities were rather remarkable. At a very early period any householder who dared to cover his house with thatch generally had the mortification of witnessing his dwelling destroyed by the authorities. In the year 1302, one Thomas Bat, citizen, came before the Lord Mayor and Court of Aldermen and bound himself and all his rents, lands, and tenements, to keep the City of London indemnified from fire and other losses which might occur from his houses covered with thatch, in the parish of St. Laurence, Candlewykestreet, and he agreed that he would have the said houses covered with tiles, about the Feast of Pentecost then ensuing. Furthermore, in case he should not do the same, he granted that the Mayor, Sheriffs, and Bailiffs of London should cause the said houses to be roofed with tiles, out of the issues of his rents aforesaid.

In the reign of King Richard the First (says Mr. Francis Edwin Tyler, in the "Home Counties Magazine"), the ward-motes ordered that all persons who dwelt in great houses within the wards should have a ladder or two, ready and prepared to succour their neighbours in case of fire; further, that all persons should have in the summer time, and especially between the feasts of Pentecost and St. Bartholomew, before their doors, a barrel full of water, for quenching such fire, if it be not in a house which had a fountain of its own; also that reputable men of the Ward, with the Aldermen, should provide a strong crook of iron, with a wooden handle, together with two chains and two strong cords, and that the Beadle should have a good and loud-sounding horn.

The first mechanical contrivance for extinguishing fire was a syringe or squirt. It was 2 ft. in length, and when in use was fastened by means of straps to the body of a man. Some were worked by three persons, two of whom held the squirt and nozzle, whilst the third worked the piston within. These early engines were much in demand, and after the Great Fire they increased in large numbers, ultimately giving way to improved fire engines. Two years after the disastrous conflagration of 1666, the City Corporation established a force of men, styled the fire-police. Each parish was provided with the following implements: leathern buckets, pickaxes, sledge-hammers, shovels, and brass hand-squirts.

The enormous damage caused by the Great Fire led to the establishing of insurance offices. The first office, the Phoenix, was founded in 1682, and its meetings and business transactions were held at the famous Rainbow Coffee House in Fleet Street. This was followed by the Hand-in-Hand (1696), and a few years later, 1706, the Sun Office was established. Each individual company kept its own engines and firemen, the latter wearing distinctive liveries.

Outbreaks of fire were very frequent, and in 1708, for the more effectual preventing of fires in the city and suburbs, it was enacted by Parliament: "That the churchwardens of each parish be empowered, at the charge of their respective parishes, to fix upon the several main water-pipes in the streets, stop-blocks or fire-cocks, also to provide a large hand-engine with a leathern pipe and socket to screw upon the fire-cock. And for the future all party walls to be of brick or stone, except the houses on London Bridge."

The year 1798 witnessed the formation of a body of men called the Fire Watch or Guard. A few years later the chairman of the Globe Insurance Office made an attempt to form a general fire-engine establishment, but it proved an utter failure. However, in 1832, eight of the then existing insurance companies formed an alliance, and thus started the London Fire-Engine Establishment. By its rules London was divided into five districts, and each was supplied with an engine house or station. There were also two floating stations, one being at Southwark Bridge, and the other at Rotherhithe.

These floating engines required over one hundred men to work them, and they threw water at the rate of two tons a minute. Gratuities were awarded to policemen who gave an alarm of fire at the nearest station. It is also worthy of note that bystanders were liberally paid for any assistance they rendered to the firemen in their endeavours to extinguish outbreaks. It required some thirty men to work each engine, so that at a large conflagration some five hundred bystanders, or even more, were employed.

We get a very faithful and amusing picture of these early parish engines in Dickens's "Sketches by Boz."

Steam was first applied to work a fire engine in 1830.

At the end of the seventeenth century a business which included the manufacture of pumps, and other apparatus for the extinction of fire, was established in Cross Street by Nathaniel Hadley. He subsequently removed to Long Acr in 1738, where he erected the first fire engine factory. In the course of time the style of the firm became Hadley and Simpkin. Mr. Moses Merryweather joined the firm as an apprentice in 1807, and eventually became head of the business.

When Nathaniel Hadley commenced business as a maker of fire appliances the manual engine of the day was a small machine drawn by means of a trolley and worked usually by sixteen men. It was an excellent engine for pumping purposes, having regard to its size, however deficient it may have been in provision for rapid transport and in other ways. The first great improvement was made in 1792, when metal valves were used in place of leather ones. The engine remained unaltered and was still of little value. Gradually, however, engines with larger wheels were constructed, having a seat for the driver and a hose-box upon which the men could ride.

It remained, however, for Mr. Moses Merryweather to construct an engine more conveniently arranged and more powerful in regard to weight and size than any of its predecessors. This important event took place in 1851, when he launched his "London Brigade Manual." Since 1851 many improvements have been made, and especially in 1885, when a new pattern valve was invented.

The first steam fire-engine was designed in 1829. Little was heard of its existence until 1879, when several similar engines were placed upon the market and were eagerly bought.

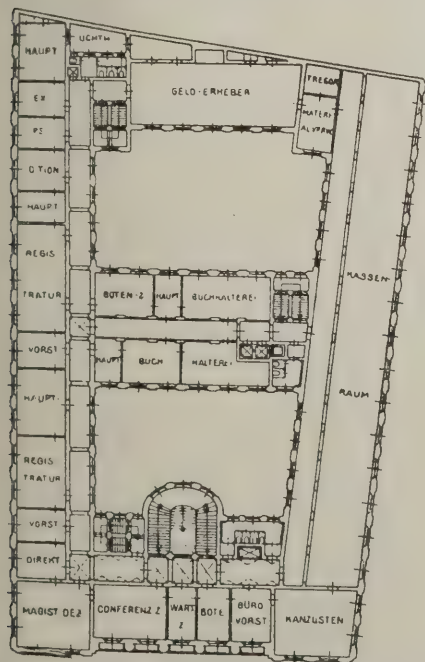

Another firm which for three-quarters of a century has been prominent in the manufacture of fire-engines and appliances is that of Messrs. Shand, Mason and Co. In 1860, the London Fire Establishment hired from them the first steam fire-engine on wheels. A second engine was purchased, and won the first prize at

London International Exhibition of 1862
In July 1863, the famous competitive trials took place at the Crystal Palace when a committee of scientific men headed by the late Duke of Sutherland, with the able assistance of the late Sir Eyre Massey Shaw, K.C.B., as secretary, raised a sum of £700 to be distributed in prize-money for the best steam fire-engine. The result was, one half of the prize-money was adjudged to Messrs. Shand, Mason and Co., while the other half was divided between two other competitors.

In 1862 a Parliamentary Committee was appointed to inquire into the existing arrangements for the protection of life and property against fire. A bulky report was issued, and the outcome was that a new force was established, under the control of the old Board of Works, the title of the force being "The Metropolitan Fire Brigade." Captain Shaw was given the post of superintendent. The force comprised about 350 officers and men. The central station was in Watling Street, in the City of London.

FIRE PRECAUTIONS IN HOSPITALS.

In a paper on "The Lay-out of Hospitals and Sanatoria," read before the Institute of Sanitary Engineers, Mr. A. Alban H. Scott, M.S.A., made a brief reference to fire precautions. Every ward, he said, should have at least two possible exits in case of fire, and the doors should be so arranged that (at least on the ground floor) a bed can be wheeled right into the open, and in the case of upper floors it should be carefully considered whether it is not advisable to have sloping ways as a second means of exit, in lieu of the usual staircase. Such a sloping way would allow of the beds being taken right down to the ground level, would cost no more for construction, and would not be more unsightly. Hydrants are seldom fixed into the actual wards, but should be so placed in corridors or outside, or both, and the hose of sufficient length so that a fire at any point of the building can be reached, and all main rooms and wards should be fitted with automatic sprinklers. In all cases the whole of the buildings throughout should be of fire-resisting construction.

THE CITY GASWORKS, BERLIN. LUDWIG HOFFMANN, CITY ARCHITECT.

FIRE PREVENTION NOTES.

*Automatic
Sprinklers.*

Automatic Sprinklers. The value and prompt efficiency of automatic sprinklers can seldom have been more strikingly illustrated than it was a short time back in the case of a motor-manufacturers' premises. Grinnell heads were being fixed throughout the building ; but before the installation was completed, the back-firing of a motor caused an outbreak in the testing-room. Very fortunately, this section of the installation had been finished, and was in working order. The sprinklers immediately began to act, and the outbreak was at once extinguished, very trifling damage being done to the premises. Sprinklers are now such an old-established institution that very probably this is by no means the only instance in their history in which they have got to work almost as soon as they were ready for it.

Another and more recent instance of the efficacy of the Grinnell sprinkler and fire alarm in preventing serious fires is reported from Lancashire. It appears that a fire broke out on January 31st in the cotton mixing room of the New Victoria Cotton Spinning and Manufacturing Co., Ltd., Bury, Lancs. Nine sprinkler heads came immediately into operation, and the fire alarm gong rang. The outbreak was rapidly extinguished, and the entire damage from fire and water was only about £250. The company have written to Messrs. Mather and Platt, Ltd., sole proprietors of the Grinnell sprinkler, to say this was the first occasion on which their sprinkler installation had been

called into operation, and they are delighted with the manner in which it works. They add that but for the prompt action of the sprinklers the fire might have reached serious dimensions. The number of fires extinguished in all classes of risks by the Grinnell sprinkler now exceeds 15,000.

*The King and
the Firemen.*

The King and the Firemen. It is evident that his Majesty the King is very keenly interested in the doings of firemen ; and, not for the first time, he has taken the trouble to express his sorrow and sympathy in a case of accidents occurring in the course of duty. Mr. A. R. Dyer, the divisional officer (north) of the L.C.C. fire brigade, who has just been honoured with the King's gracious message, was standing on a platform or floor about 14 ft. above the ground-floor of a White-chapel building, which was alight, when a portion of the roof fell, tilting the platform, from which Mr. Dyer was thrown to the ground-floor. At the hospital he was found to be suffering from fracture of the skull, concussion of the brain, and fractures of the collar-bone, shoulder-blade, and three ribs. Notwithstanding the terrible extent of his injuries, Mr. Dyer, it is gratifying to learn, is making satisfactory progress towards recovery. Another instance of self-sacrificing devotion to duty at a recent fire is recorded in the case of station-officer William Cox, who has just been awarded the London County Council's silver medal for "extraordinary bravery." A fire was well alight at a confectioner's shop in the

Mile End Road, and Cox, hearing that there were persons in a back room on the first floor, made his way through dense smoke and intense heat, and rescued from the room a police-sergeant, who was lying unconscious, and a little girl. The little girl he passed out of the window, but the police-sergeant had to be dragged down the staircase through the stifling heat and smoke. Another fireman ascended the staircase to help Cox with his burden; and Cox, on reaching the outer air, collapsed, and had to be revived by means of artificial respiration. We yield to none in our admiration of the courage and devotion of our firemen; but this feeling is too often tinctured with regret that so much suffering and self-sacrifice ought to be unnecessary, and should be rare indeed when at length the subject of fire-prevention is more generally and more intelligently understood.

Brigade Competitions.

In last month's Fire Prevention Notes, approval was expressed of the practice of arranging competitions for firemen. Apparently the London County Council Fire Brigade Committee are quite alive to the advantages of pitting men or brigades against each other in trials of skill, for they have just resolved to recommend to the Council "That members of the London Fire Brigade be permitted to take part in the horsing and driving competition for fire brigades at the International Horse Show, 1912, provided that, if any money prizes be awarded to the men, the money shall be handed over to the London Fire Brigade Widows' and Orphans' and General Benefit Fund"—surely a wise, as well as a benevolent provision, getting rid of any mercenary element, and substituting for it an encouragement of the purely humane feeling which seems to animate every member of the brigade. It may be remembered that at last year's exhibition at the Horse Show, the London Brigade representatives were successful in winning the challenge cup and a number of minor prizes. As horses are so rapidly disappearing from the brigade, it seems to be only a question of time for fire-brigade competition to become strangely irrelevant at a horse show.

Architecture of Fire Stations.

It is gratifying to notice that, in connection with the proposed erection of a fire station at the junction of Eton Avenue and Lancaster Road, N.W., the question of architectural treatment has been raised. It has been found that it will be necessary for the Council to enter into covenants as to the user of the site which will preserve the amenities of the adjoining portions of the estate of the freeholders (the authorities of Eton College), and will prevent the erection on the site of any building other than a fire-station except a building in conformity with the adjoining property. A fire-station being innately noble by its purpose, we have often wondered why greater efforts have not been made to give architectural expression to that nobility. There is no reason at all why the front of a fire-station should be destitute of artistic feeling, nor why one stereotyped style should be thought to be universally applicable to the often widely divergent environment found in various quarters of a large town. Most of the stations in and around London have, it is true, the dignity of simplicity; this negative virtue, however, is not enough.

BOOKS.

Public Health Law.

As the public health laws grow continually in complexity, guides to their interpretation become, *pari passu*, increasingly necessary, and perhaps sufficiently numerous. Mr. Bertram Jacobs has just issued a manual which, beyond its undoubted merit of being the latest in the field, is less fortuitously distinguished by its clearness of statement and its firmness of exposition. Moreover, more than the usual amount of attention has been paid to the not unimportant subject of what may be called proportional representation—that is to say, it is clearly recognised that certain points require much fuller treatment than others. For example, Parts III. and IV. of the Public Health Act, 1875, the Public Health Acts Amendment Act, 1890, and the further amending Act of 1907, are treated in fairly complete detail, these containing the undoubted substance of our sanitary legislation; but the remaining parts of the Act of 1875, and other statutes than those mentioned, are treated more or less fully according to the author's view of their importance or of the directness of their relationship to the subject of the work. Manuals of the law are, roughly speaking, of two classes—those very elaborate treatises that are intended for the use of the legal profession, and those more definite and dogmatic expositions that are destined for the enlightenment of the laity. Seldom indeed can it be said of a law-book that it will serve both these purposes equally well, and we should not care to advance such an inherently incompatible claim for the book under notice. Still, however diffidently we may venture to suggest that this manual will be found useful even by the professional lawyer, we have no hesitation in affirming its value to all those who, not being lawyers, are, however, constrained to acquire a sound working knowledge of the health laws, whether for the purpose of preparing for any of the several examinations in which such knowledge is required, or for that of administering, in some capacity, the laws here expounded.

The drain or sewer question is dealt with at some length, and the definition given by the author is fortified by the citation of many judicial decisions, as well as illustrated beyond possibility of misconception by surely the roughest diagram that ever found its way into print. Both definition and diagram, however, are characteristic of the plain common-sense method of treatment observable throughout a book in which concise expression not only makes for clearness, but enables the author to deal with his subject quite comprehensively yet within comparatively small compass.

A Manual of Public Health Law. By Bertram Jacobs, Barrister-at-Law. London: Sweet and Maxwell, Ltd., 3, Chancery Lane, W.C. Pages xvi. + 204, 8½ins. by 5½ins., price 7s. 6d.

The Study of Church Buildings.

In a new edition of Mr. Sidney Heath's admirable little book on "Our Homeland Churches and How to Study Them," the work has been remodelled, extended, and further illustrated, a new feature being a series of carefully drawn architectural details by Mr. J. R. Leathart, while the glossary has been amplified to three times its original bulk. The book has been altered as to its *format*, and is now uniform with the "Homeland Pocket Book" series. Consequently it

can be easily slipped into any ordinary pocket, and cheerfully borne therein without the least feeling of encumbrance. The illustrations have been chosen with unusual care, and are supported by letter-press that is not only legible and even beautiful as a matter of typography, but is interesting and informative as to its subject-matter.

Our Homeland Churches and How to Study Them. By Sidney Heath. With many illustrations from drawings by J. R. Leathart and others, and from photographs. (The Homeland Pocket Books, edited by Prescott Row and Arthur Henry Anderson.) London: Frederick Warne and Co., Chandos Chambers, 15, Bedford Street, Strand, W.C. 198 pages, 5½ins. by 4½ins., price 2s. 6d. nett.

BIRMINGHAM COUNCIL HOUSE EXTENSION.

The Birmingham Council House extension is now rapidly approaching completion. The architects are Messrs. H. V. Ashley and Winton Newman, of London. Last week Mr. Ashley read a paper on the subject before the Birmingham Architectural Association, at the Exchange Buildings, Birmingham, when Mr. C. E. Bateman (president of the association) occupied the chair.

Mr. Ashley, in the course of his paper, said it was interesting to note that the plans in the second competition had been very little altered. The site was practically four-square. On the east, or Margaret Street, front was the Education Department, consisting of four floors of innumerable offices; on the south, or Edmund Street, front, and in the interior of the site, was the Gas Department; and on the west, or Congreve Street, front, including three floors, were the offices of the Health and Tramways Departments, both of which had already outgrown their new quarters since the extension of the city. On the first floor over the Gas Department were the new picture galleries, and on the second floor of Congreve Street the Natural History museums, both approached from the present Round Room over the new bridge across Edmund Street. The completion of the extension on the north side was now in hand, and would give further accommodation for the Tramways, Health, and Gas Departments, including, in addition, further picture galleries and museums for casts on the upper floors, with a special entrance devoted, as it were, to the Feeney galleries. Each of these departments was self-contained—each had its own main entrance and staircase, and at the same time there was easy access between the departments.

Internally, the finishings were of a very simple character—a little interest had been given to the entrance staircases and to the committee rooms, and one or two of the larger offices, but in the main they had to remember that the building was an office building. In addition to oak and maple batten and block floors, they had made extensive use of linoleum as a floor covering—particularly in the footways to the art galleries and in the panels in the corridors with marble surrounds. The walls and ceilings generally were plastered, and some of the rooms and staircases were panelled out in this material with certain parts enriched, while oak panelling had been adopted in the committee suites of the gas and education departments. The lower part of the gas department entrance hall and the dadoes to the main staircases to the other departments had marble linings, echelon bands, and alabaster fillings to the latter, and Hopton Wood

tone to the former. The principal staircases also had echelon treads, risers, and trings. The art galleries were lighted by day on what might be described as the ceiling light principle as against the lantern light. This system was not adopted until exhaustive enquiries and research had been made. Further, they would realise the lantern light presented considerable difficulties of construction, added to which they very much involved the problem of heating and ventilation. The heating of the building was by low-pressure hot water mechanically circulated—a very simple and trustworthy method. The ventilation was generally by the offices by means of extracts in the rooms, into ducts over the corridors, with cast shafts at intervals, finishing at the top with fan chambers. The art galleries had the glass of the ceiling lights slightly raised on fillets and extract fans in the tables exhaust from the roof spaces. The only downward ventilation was in the large gas office, where a large extract fan joined the base of the chimney stack, the foul air being forced up around the smoke flue from the boilers. Much interesting joinery was scattered throughout the work.

Mr. Whitworth Wallis proposed a vote of thanks to the architects for their paper, and spoke of the friendly relations which had existed between them and the Corporation officials. Referring to the bridge over Edmund Street he said the disciples of Ruskin were down on it, and all sorts of criticisms had been passed on that part of the structure. Personally, however, he did not care at all what the bridge was like outside, so long as it was beautiful within, and he could assure them that they had in it one of the most charming entrances to any art gallery he was acquainted with. As to the galleries themselves, they were beautifully lighted, well-proportioned, and free from bridecake ornament, which was nothing but a trap for dust, and distracted attention from the works of art on the walls. The motion having been carried with applause, Mr. Newman replied, and defended the bridge as supplying a stone connection between the old and the new buildings.

PICTURE EXHIBITIONS.

The Fine Art Society.
At this society's rooms is a collection of water-colour drawings of New Forest scenery, by Mr. Wilfrid Ball, whose work shows at its best in the small landscapes, which are admirable both in water-colour style and the true impression they give of the landscape of the beautiful country of the New Forest. For some reason, in the few drawings that are on a larger scale, the artist seems to lose in some degree the broad and clear style of the smaller landscapes. But the latter, which form the larger portion of the exhibition, are beautiful examples of landscape-painting in water-colour.

The '91 Art Club.
This club, which derives its name from the fact that it was started in 1891, holds exhibitions only for a few days each year, and was this year installed at the Pine Club Gallery from February 10th to March 4th. It appears to be entirely an exhibition of lady artists, and contains some good work. Among the paintings those of Miss Eleanor Ramsay, hon. secretary, are the most important;

her two large landscapes, "Rye" and "Drifting to the Dawn," are fine works; also a smaller one, "The Pathway to the Sea." Miss Frances Ramsay paints figures well, including a life-size portrait. Among other good contributors are Mrs. C. R. Walton, Miss Lota Bowen, whose landscapes have charm of colour as well as composition; and Miss E. M. Brebner has some good flower paintings. There are other good oil and water-colour pictures; also, it must be admitted, a good many that are not worth very much. The best things in the exhibition are some of the small works in bas-relief sculpture, by Miss Rope, a well-known sculptor, and Miss Lilian Edmonds, a clever painter who has only recently taken to sculpture; her "Virgin and Child" and "Cupid all Armed" are beautiful little designs in low relief. There are some cases of good jewellery work by Miss Riley, Miss Kinkead, Miss E. C. Woodward, and the Misses Frances and Violet Ramsay.

FIRE TESTS OF GLAZING AND REINFORCED CONCRETE DOORS.

The British Fire Prevention Committee's testing operations on Wednesday of last week comprised fire tests on a series of window openings glazed with "Copperlite" glazing, no panel of glazing exceeding 4 ft. super., and twelve panels being under test for varying periods of 60 minutes and 90 minutes, under the Committee's standards. "Copperlite" glazing had not been previously officially tested by the Committee, and the recording of its standard of fire resistance is thus of considerable technical interest.

There were further tests with two reinforced concrete doors made for the Committee for experimental purposes and submitted for the Committee's standard 2½ hours high temperature fire test. Here again work that had never before been under official examination was under observation.

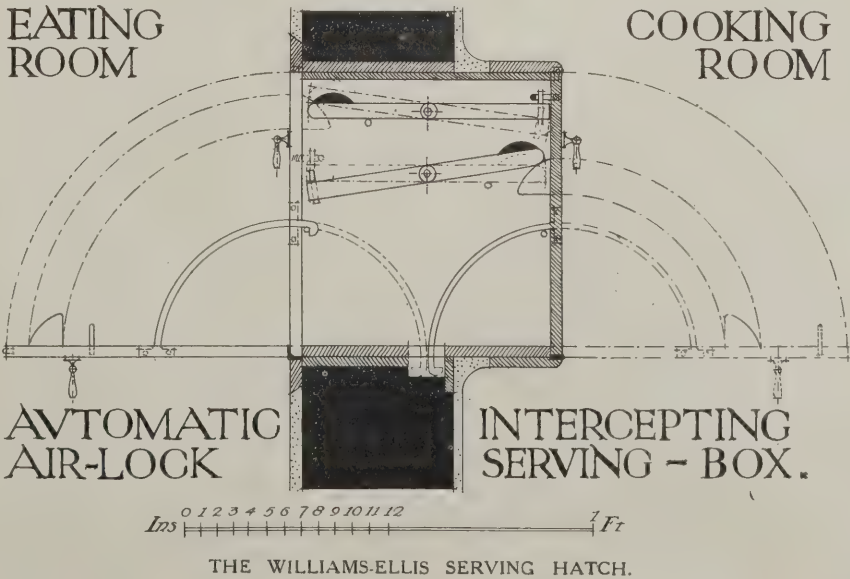

The results of the tests are not yet published. The Committee's Council was represented by Sir Henry Tanner, I.S.O., F.R.I.B.A., and Major A. McN. Cooper-Key (Ch. Insp. Explos. H.M. Office), and its Executive by Mr. Horace S. Folker, F.A.I. (Hon. Treasurer), and the Testing Sub-Committees comprised Messrs. Max Clarke, F.R.I.B.A., J. Herbert Dyer, R. W. Henderson, Bertram Chatterton,

A.M.Inst.C.E., C. T. Cuss, and J. W. Brooker, with Mr. Ellis Marsland as directing member. Among those attending were representatives from the Home Office, Office of Works, General Post Office, etc., etc., and also M. Welsch, late Chief Officer of the Ghent Fire Brigade.

A SERVING HATCH.

With the ordinary serving hatch between dining-room and kitchen, noise and smell from the latter may pass into the dining-room through the opening. To overcome this defect, several devices have been contrived. One of these comprises a sort of barrel with open sides, mounted vertically and fitted with shelves; with which arrangement the dishes are put in on the kitchen side by the cook, who then turns the barrel so as to bring the dishes round to the dining-room side, where the maid is waiting for them. Another device is shown by the illustration on this page. This is the invention of Mr. Clough Williams-Ellis, architect, of Arundel House, Victoria Embankment, W.C., who has obtained Provisional Protection for the gear. It has been fitted successfully in operation. One, we believe, is in the delightful little house in Reed Pond Walk, Romford, which has been built from the architect's designs, and was among those illustrated in our last Edition de Luxe. The greatest demand for such a device would seem to be in houses carried on with a staff of one to three servants; that is to say, in houses costing from £400 to £1,500. Mr. Clough Williams-Ellis is making arrangements for placing the gear on the market, when it will be obtainable for "a few shillings."

The action is a cam and lever one operated by two hinged hatches. Imagine the dining-room hatch to be open, as shown in the cross-section. Then the upper lever has its weighted end resting on a stop, the pin at the other end engaging a hook fixed on the inside of the kitchen hatch. Now imagine that the dining-room hatch is closed. Its cam will thus be brought into action, the weighted end of the top lever will be raised, and the kitchen hatch thus released. Thus one or other of the hatches may be opened separately, but not both at once, though both may be closed together; and in this way the passage of sound, draught, and smell from one room to the other is prevented.

ENQUIRIES ANSWERED.

Preparation of Damp Walls.

H. E. C. (London) writes:—"A house built in a very exposed position has walls constructed of 9 in. brickwork covered with 1 in. cement rough-cast. It is found that upon the south-west side water has penetrated after heavy rain from that quarter. Is there any preparation on the market which can be applied easily and inexpensively to the rough-cast to keep out the moisture? If so, must the walls be allowed to dry first?"

—There are several petrifying solutions or silicate paints on the market which should prove suitable. These are transparent, but there is probably no objection to the use on rough-cast of Duresco washable water paint (outside quality) after a previous coating with the petrifying liquid supplied by the makers of Duresco, who will furnish directions for use if so requested. The work should be dry before application of solution.

G.

Supporting a Stone Cupola.

SUBSCRIBER writes:—"It is necessary to construct a stone cupola as an addition to a building now in course of erection. The ground level is formed with concrete beds 12 in. thick, 2 ft. 3 in. wide, under 9 in. walls, and 4 ft. 3 in. wide under the front wall. The building is 25 ft. to the main cornice. It is intended to carry the cupola on two 10 in. by 6 in. R.S. joists resting on 18 in. by 4½ in. piers and walling with 8 in. by 6 in. joists resting on these, and the front wall placed alongside the 9 in. walls, all bolted together. Kindly say if the construction is satisfactory."

—The 9 in. walls with the 18 in. by 4½ in. pilasters are hardly sufficient to carry the weight of the superstructure, and it will be advisable to strengthen them by a 12 in. by 3½ in. by 26.1 lb. or a 10 in. by 3½ in. by 23.5 lb. channel steel run up the face of each pilaster, with angle cleat and plate on top to relieve the walls of part of the weight from the 10 in. by 5 in. joists. These channels should have proper bases and foundations. A grillage of rolled joists to carry the circular drum will enable a 4 in. by 3 in. rolled joist to be carried up from the centre to support the pineapple if a sufficient bearing for the joists can be obtained on the walls, and this will relieve the structure of the weight of the corbelling.

HENRY ADAMS.

Acquisition of Land under Finance Act, 1910.

D. S. writes: "Kindly say whether public bodies can acquire land at the price assessed by the valuers under the Finance Act, 1910, or any other Act."

—Public bodies can acquire land compulsorily under various Acts of Parliament specially passed for that purpose. They are all of a strictly limited character, and all require that the price should be settled by arbitration, if the parties cannot agree. There is no such general provision in the Finance Act, 1910, or its present amendments.

F.S.I.

St. Botolph's, Bishopsgate.

POST WREN (Cornwall) writes: "Kindly give some information about the church of St. Botolph, Bishopsgate, London. Do any published works give an account of it? The church, I believe, is the only known work in Later Renaissance by an architect named John Gold."

—The present church of St. Botolph, Bishopsgate, was erected between 1725 and 1729 at a cost of over £10,400, the old church having been demolished because of its ruinous condition. James (not John) Gold is stated to have been the architect, but the available information concerning him is very meagre. All the authorities we have consulted simply state that Gold was reputedly the architect, and that confirmatory evidence is very scarce.

St. Botolph's is a spacious, though not lofty, building, having two aisles, which are separated from the main body by composite columns. The steeple is placed at the east end, and consequently the chancel is situated beneath the tower. The ceiling is arched, and embellished with ornamental panels. In 1820 a lantern was introduced in the centre for the provision of additional light in the body of the church. There are galleries at the north, the south, and the west. Externally the church is of red brick with stone dressings, the steeple being wholly of stone. A fairly comprehensive account of the building is given in A. E. Daniell's "London City Churches," published by Constable and Co.

Silicate Solution for Exposed Chimney-Breast.

A. K. (Purley) writes: "Please advise as to whether it is feasible to utilise soda silicate (water-glass), or a combination of that and other substances, for the treatment of a chimney-breast built, in an exposed position, of Sussex dark stocks, which it is not desired to cover with cement or roughcast, the defect being that the heavy rains drive through it." (J. K. G. also asks a similar question.)

It is certainly practicable to use silicate solution for the purpose mentioned. One of the prepared petrifying paints will probably prove suitable, such as Szerelmey's silicate paint, or Blundell's. The work should be thoroughly dry before application, and more than one coat may be necessary. Messrs. Blundell, Spence and Co., of Hull, issue a useful guide to the use of petrifying liquids. All these solutions, though transparent, tend to deaden the appearance of the work after application.

Reinforced Concrete String Course.

T. M. writes:—"I enclose a sketch showing details of a store building. The string course is entirely broken away from the floor by the 7 in. by 4 in. R.S. joist that carries the 9 in. wall, and acts as a tie between the stanchions. This string course is used as a reinforced concrete beam between the brick piers, and is held in the lateral direction by three ¾ in. cross-bars from floor through web of 7 in. by

4 in. joist, and which are twisted round the longitudinal ½ in. rod running between the piers. It is thought that this forms a poor detail, and that the string course will shrink away from the joist and the rain will penetrate the joint between the brickwork and string course, and get

between the string course and the joist. I should be glad of your opinion."

—The detail has defects inseparable from mixed forms of construction. If the rest of the structure were of reinforced concrete the defect feared would not be likely to arise. If the 7 in. by 4 in. steel joist must be retained in its present position, liability for wet to penetrate the joint between brickwork and string course will be reduced if a 1 in. sinking is made above the external weathering (see alternative sketch), as in this case that particular joint will be no more liable to admit wet than any other of the horizontal brick joints. But why not omit the 7 in. by 4 in. joists, and build reinforced brickwork between the piers, the hoop iron in the joints making the 9 in. walls self-supporting and tying the piers by being carried through them? G.

Stress on Column.

QUAN writes:—"What assumptions should be made, and what is the maximum tensile stress on a column loaded as sketch?"

—The information supplied is insufficient to determine the full stress on the column. The length to the change of diameter should have been given, the centre distance between the columns and the area of surface of side and roof exposed to the wind. Taking the eaves of roof as a fulcrum, the stresses due to the given load are

$$\frac{W}{A} \pm \frac{M}{Z} = \frac{7+3.5}{34.36} \pm \frac{3.5 \times 6 \times 12}{67.13}$$

= 3.375 ± 4.05 tons per sq. in. compression, and 3.45 tons per sq. in. tension. As the safe working stress is not more than 1.75 tons per sq. in., the column is not strong enough, even without making any allowance for wind.

HENRY ADAMS.

Dispute Between Architect and Contractor.

G.S.W.L. writes:—"A firm of contractors was engaged to erect a building, the architect being appointed sole arbitrator. The bill of quantities did not form part of the contract, although there was a clause in the specification stating that the contractors should supply the architect with a copy of their priced bill of quantities, and that such prices should be the schedule of prices for any extra or omitted works upon which the architect should decide. The contractors exceeded the agreed time for completion, refused to remedy alleged defects, and presented the architect with a bill, whereas the architect's statement of accounts showed that an amount was due from them to his client. The contractors say that the contract was a lump-sum contract, and that no deductions of any kind

can be made from it. Please advise with regard to this matter."

—The following facts appear to be evident:—(1) That the quantities are not part of the contract, and therefore it is a lump-sum contract, and only omissions of the work originally contemplated and additions to that work can be taken into consideration. If the original quantities for the work executed were full, the contractor must be allowed to reap the benefit; if they were insufficient, he must stand the loss. (2) That although the time for the completion of the work was exceeded, and complaint made of the fact, there does not appear to have been any enquiry into the matter by the architect, nor any judgment by him at the time as to the responsibility for the delay. As mentioned in regard to a previous enquiry (*vide* "Architects' and Builders' Journal," January 17th, page 66) it seems to be necessary, before the expiry of the contract period for completion, for the architect to enquire into the question of time, and to grant allowance of time where the contractor is entitled to it, or the penalty clause fails. (3) Although the architect was appointed sole arbitrator, should his own conduct be called into question the court will usually set him aside, and refer the matter to an independent arbitrator. (*Freeman and Sons v. Chester R.D.C.*). (4) That the client has a counter-claim for non-delivery, which may be valid against either the contractor or the architect, or both, according to where the fault lies, unless the client himself has contributed to the delay by own acts.

A. G. W.

Timber Roof Truss.

TIMBER writes:—"I enclose tracings [not reproduced] showing diagrams of a proposed wooden roof truss for a public hall. Kindly advise with respect to the construction."

—The designs submitted are typical of a class of imperfect truss for which no stress diagram can be made until other members are added. The structure proposed is altogether too flimsy, even for a temporary structure in a sheltered situation. A public hall 45 ft. wide, with ground floor and first floor to be used for dancing, and having a high-pitched open-timber tiled roof, needs substantial walls or very efficient bracing, and the design must be worked out on a very different basis before it is worth while to spend time in criticising it.

HENRY ADAMS.

Competitions for Students.

J. W. B. (Oldham) writes:—"I am anxious either to sit for an examination or to compete for any prize that may be offered by such institutions as at South Kensington, etc. The R.I.B.A. and S.A. exams. (final) are too advanced for me. Can anything be got for preparing a set of drawings for some given subject?"

—The South Kensington exams and prizes are practically confined to pupils at recognised art or technical schools. Two valuable prizes open to all members of the architectural profession are periodically awarded by the Architectural Association. They are: the Banister Fletcher Bursary, value 25 guineas, given for a selection of measured drawings and descriptive report of the buildings illustrated (annual), and the Saxon Snell Scholarship, value £50, awarded triennially in rotation by the A.A., the R.I.B.A., and the R.San.Inst. for subjects connected with the improvement of hospital design. This usually takes

the form of a design and report for some building such as a cottage hospital or a convalescent home. Particulars may be obtained from the Association Brown Book. The R.I.B.A. prizes and student-ships are open to all British subjects, but are presumably too advanced. G.

Responsibility for Defective Tiles.

Z. writes:—"A tile submitted by a builder has been approved by the architect. After the tiles have been laid, it is found that they are absorbent, and must be replaced. Who is to bear the loss?"

—Possibly the amount of the loss could be recovered from the vendor of goods that have been found to be unsuitable for the purpose for which they were supplied. It must not be overlooked, however, that the building owner is entitled to rely on the architect for protection in such matters, and that the architect having accepted the tiles, apparently the builder is free from legal responsibility as to the choice and its results, unless, indeed, it can be conclusively shown that he had some peculiar interest in introducing the goods. It seems, therefore, that the architect should do his utmost to get the matter settled without loss to the building owner. In order to secure rectification, it might be advisable to withhold payment for the work. This course would possibly stimulate the builder to seek indemnification from the vendor. Failing a satisfactory issue of private negotiations, the building owner might sue the vendor for the loss sustained. The particulars furnished by the querist, however, are too meagre to form the basis of a definite opinion. Failing a reasonable result of private conference, the case should be stated in full detail to a competent solicitor, who would then be in a position to offer sound advice as to the best course to pursue.

LEX.

Buildings to Measure near Teddington.

S. W. H. (TEDDINGTON) writes: "Kindly recommend a building somewhere in this neighbourhood, or in Surrey or Middlesex, suitable for the intermediate R.I.B.A. Testimonies of Study (old form)."

—Querist presumably desires work which can be measured for sheets 4 and 5 of the Testimonies. The district is not architecturally rich, the finest work being that near at hand at Hampton Court Palace, where, in the older parts, suitable details for one sheet may readily be found. Within cycling distance, there are, of course, many churches from which a window or other detail of the Early English or Decorated period might be taken. Banstead is one such; though externally modernised, the arcade would make a good subject in the interior. G.

Light Roofing Material for Flats.

A. H. (LONDON), writes: "A terrace of fifteen houses in London is roofed with zinc flats, which, after having been satisfactory for some thirty years, are now a great source of expense. Kindly suggest a fire-resisting material which it will not be necessary to cover with gravel and coke breeze in order to comply with the fire regulations of the L.C.C."

—Any of the numerous patent multi-ply roofing materials which have rubber and rubber substitutes as their form of waterproofing require to be covered for protection from risk of fire. This may be done either with $\frac{3}{4}$ in. sand topped by

$1\frac{1}{4}$ in. of fine gravel (to pass a $1\frac{1}{4}$ in. ring), or with 1 in. of concrete or tarpaving. Several firms, however, lay ordinary asphalt in two coats on felt laid on roof boarding, and this requires no such protection. G.

Conversion of Residential Property.

"SUBSCRIBER" desires to know whether in the changed circumstances of a neighbourhood, which make the conversion of what has hitherto been residential property into shop property the only alternative to letting it for apartment houses, the courts would be likely to grant an injunction in the event of the owner of an apartment house, relying upon an old covenant forbidding the houses to be used for business premises, seeking to restrain an adjoining owner from converting his property into a shop.

—The answer is in the affirmative; but seeing that other neighbouring owners are actually converting, it might be possible to arrange for the abrogation of the restrictive covenant by mutual consent, if the matter were tactfully handled.

A. G. W.

The "Fair Wear and Tear" Clause.

SUBSCRIBER (PORTSMOUTH) writes: "In an agreement for a three years' tenancy, the following clause occurs: 'And also (the tenant) will at all times during his occupation of the said premises, keep and maintain the same in good tenantable repair, and so deliver up the same at the end or sooner determination or the said term (fair wear and tear and damage by fire excepted). The points at issue are: (1) Does the fair wear and tear clause qualify the first part of the agreement, or exclusively the latter part only? (2) Would any sort of repair—decorative or constructional—necessitated or required by the tenant during his occupancy devolve upon him, or, under the fair and wear and tear clause, upon the landlord? (3) Does not the fair wear and tear clause apply exclusively to the condition of the house at the time of yielding up possession?"

—The intention of the maintenance clause quoted is that, whatever the condition of repair of the premises when taken over by the tenant, he shall maintain them in that condition by suitable repairs as and when required, and at the end of the tenancy shall hand over the premises in as good a condition of repair as that in which he received them, except in so far as that condition has suffered by reason of fair wear and tear, due to the legitimate usage of the premises for the purposes specified in the conditions of tenancy. In answer to the specific questions: (1) The words "fair wear and tear," etc., qualify the "good tenantable repair," otherwise an owner who let a tenant a new house would be entitled to require back from him a new house at the end of the tenancy; (2) the tenant has to do all repairs required during his tenancy. Sometimes this is mitigated by a provision in the agreement excluding repairs of a structural character, such as arise when dry rot affects the stability of wooden floors; (3) the fair wear and tear clause comes into operation whenever a comparison has to be drawn between the state of repair of the premises when taken over by the tenant, and the state of their repair on any later occasion, if the owner claims that the tenant had not fulfilled, or is not fulfilling, his covenant to "keep and maintain in good tenantable repair."

A. G. W.

LONDON MASTER BUILDERS'
ASSOCIATION.

The fortieth annual general meeting of the London Master Builders' Association was held in the Council Chamber, Koh-i-Noor House, Kingsway, W.C., at 4 p.m., on February 29th. The President (Mr. G. Bird Godson) at first occupied the chair, which was afterwards taken by Mr. James S. Holliday, the newly appointed President.

The minutes of the last annual general meeting, the subtended annual report of the Council, and the audited accounts for the year ending December 31st, 1911, were read and approved.

The following officers and members to fill up rota vacancies on the Executive Council were elected for the coming year:—President, Mr. James S. Holliday (Messrs. Holliday and Greenwood, Ltd.); Senior Vice-President, Mr. Walter Lawrence, jun. (Messrs. Walter Lawrence and Son); Junior Vice-President, Mr. W. F. Wallis, J.P. (Messrs. G. E. Wallis and Sons, Ltd.); Treasurer, Mr. Edmond J. Hill (Messrs. Higgs and Hill, Ltd.); Council: Messrs. C. E. Allen (Messrs. Allen and Co., Pimlico), F. J. Gayer (Messrs. E. A. Roome and Co.), R. J. Holliday (Messrs. Holliday and Greenwood, Ltd.), F. M. May (Messrs. Holland and Hannen and Cubitts, Ltd.), F. G. Minter, W. J. Renshaw, Howell J. Williams, J.P., L.C.C. (Messrs. H. J. Williams, Ltd.), Hy. Wall (Messrs. Chas. Wall, Ltd.), Walter Wood (Messrs. F. and F. J. Wood). Honorary Auditor, Mr. E. S. Blake (Messrs. W. E. Blake, Ltd.).

A hearty vote of thanks was given to Mr. G. Bird Godson for the able and assiduous manner in which he had discharged the duties of President during the past year.

The Trades Disputes Act (1906) was considered, and the meeting desired unanimously to lodge a petition against the said Act in the House of Commons.

Instructions were given to secure the signatures of all the members of the association, and they are earnestly requested to sign.—THOS. COSTIGAN, Secretary.

The annual report, presented and adopted at the above-recorded meeting, includes the following items:—

State of the Building Trade.—During the past year there has been an improvement in the building trade, but the abnormally keen competition which prevails renders it difficult to carry on business on anything like profitable lines.

Matters affecting Contracts.—The Institute of Builders formulated amendments to Clauses 20 and 28 of the Agreed Contract, together with a new form of contract for sub-contractors. These proposals were laid before this Association and were approved. Further steps in the matter are now being taken.

Organisation.—This matter has received earnest attention during the past year, and, as a result, many important firms have become members. The London Association of Master Decorators has become affiliated to this Association.

Parliamentary.—The National Insurance Bill has been carefully considered in co-operation with other bodies. The Council is glad to recognise that public attention is being drawn to the gross abuse of the Trades Disputes Act (1906), and they are associating themselves with other bodies in pressing upon the Government some action to put an end to the abuses existing under the Act. Careful attention has been given to several other

Bills before, or to be brought before, Parliament, and they have been referred to the Employers' Parliamentary Council.

Lead Poisoning.—Mr. F. G. Rice was appointed representative of this Association on the Home Office Departmental Committee appointed to consider matters relating to the dangers arising from the use of lead in painting, to collect evidence, and to report thereon. The Committee appointed has held many protracted meetings, and the building trade is under great obligations to Mr. Rice for the interest, attention, and ability which he has devoted to the subject.

Legal Cases.—The case of C. P. Roberts v. Hickman and Co. was carefully considered. The case was finally taken to the House of Lords, where judgment was given in favour of the builder. A condensed report of the proceedings is given at page 122 of the I.M.B.A. Handbook.

Relations with the Workmen.—The labourers applied for the formulation of a working rule agreement, but the Council could not consent to the proposal. The Council declined to consider any application for an increase of wages to smiths and hammermen, as there was no working rule agreement between their societies and this Association. Six months' notice of the termination, on June 8th, 1912, of the working rule agreement with the Amalgamated Society of Carpenters and Joiners was received. A copy of a new working rule agreement was also received, but the Council of this association could not accept it as it was proposed and signed jointly by the Amalgamated Society of Carpenters and Joiners and by the Furnishing and Cabinet Makers' Societies, the latter not being a recognised branch of the building trade.

Work of the Council.—Amongst other matters the Council have given careful attention to the following:—(1) Suggestions from the Quantity Surveyors' Association as to items to be embodied in all Primary Bills of Quantities. (2) A movement on the part of organised workmen to obtain permission to use the Labour Exchanges for other purposes than those for which they were intended.

MR. JAMES S. HOLLIDAY,
The newly elected President of the London
Master Builders' Association.

YORKSHIRE FEDERATION OF BUILD-
ING TRADES EMPLOYERS.

The monthly meeting of the Executive Council of this Federation was held in the Council Chambers, Town Hall, Hull, on February 15th, when 67 delegates were present from the federated associations.

The Deputy-Mayor (Ald. H. Feldman, J.P.), in the absence of the Mayor through illness, extended a welcome to the Federation.

The President called the attention of members to the death of the late Alderman Judge, of Wakefield, on January 24th. The Federation was represented at the funeral.

It was reported that protests had been received from 16 towns, containing 556 signatures, against the undue haste in which the National Insurance Act had been rushed through Parliament against the definite promise of the Chancellor of the Exchequer. It was resolved to bring the matter before the National Administrative Committee with a view to National action being taken, and to request the other Federations to associate themselves with the protest. The local associations were desired to make an earnest endeavour to complete the returns not later than March 14th.

It was resolved to submit the name of the president to the National Health Insurance Commission as an eminently qualified person for appointment on the advisory committee to be appointed by the National Health Insurance Committee.

The recommendation of the Northern Centre that the three constituent federations should continue the payment of subscription to the National Federation on the commuted basis was considered, and the Federation approved of the subscription to the National Federation being assessed for the present year at a certain sum that was specified.

The President reported upon the proceedings at the annual meetings of the National Federation held in London in January last.

Mr. Sinclair reported that the question of non-union labour as raised in connection with the Leeds case was heard by the National Conciliation Board on February 1st. After the parties had presented their case, and the Leeds witnesses retired, the matter was adjourned, as the question is also raised on the notices for alteration of rules which come up for consideration at the annual meeting of the Board in May.

Mr. W. R. Thompson reported that at the invitation of the Town Clerk of Huddersfield a deputation of the Federation, consisting of himself, Mr. T. E. Taylor (Bradford), and the Federation Secretary, had waited upon the Town Clerk on February 13th, to lay before him reasons in favour of the application of the Federation for the insertion of an independent arbitration clause in the contract form of the Huddersfield Corporation. The deputation had a pleasant interview with the Town Clerk and City Surveyor, and after a frank interchange of opinions, the Town Clerk promised that the views of the Federation would be laid before the Committee of the Corporation having the matter in hand.

The revised draft of the West Riding County Council was referred to as including the words, "but it shall not be a condition that trades union men only shall be employed." The copy of the revised clause as circulated after the last meeting is therefore confirmed.

It was decided to urge the National Administrative Committee to request the President of the Local Government Board to receive a deputation with respect to official action being taken whereby local authorities should not only be urged to impose standard conditions for the protection of honourable employers and competent workmen, but also to observe standard conditions in respect of contracts between such authorities and federated employers.

The receipt of the revised conditions of contract issued by the West Riding County Council was reported. The conditions were referred to the Emergency Committee for consideration and report.

Mr. Hollingworth, on behalf of the Huddersfield Association, invited the Federation to hold the next meeting in that town, and the date was fixed for March 21st.

The annual dinner of the Federation was afterwards held in the City Restaurant, Hull, when 180 members and friends were present, Mr. J. Townsley, president, presiding.—Condensed from report by J. DAVIDSON, Secretary.

TRADE AND CRAFT.

"The Charm of a Panelled Room."

Under this title Messrs. Higgs and Hill, Ltd., Crown Works, South Lambeth Road, London, S.W., have issued an elegant booklet emphasising by description and illustration "the distinctiveness and refinement of good oak panelling." The rooms illustrated have been executed by Messrs. Higgs and Hill to the designs of leading architects; and it is rightly insisted that "in important work an architect should be consulted, whose knowledge and taste enable him to adapt the style of his design to suit the requirements of the building and its furniture." The firm make a speciality of panelling, their shops being equipped with the most modern machinery and facilities for turning out high-grade work at an extremely low price; while the joiners engaged are first-rate craftsmen of expert skill and experience in this class of work. The firm also keep large stocks of oak, which is stored on their extensive works, which cover an area of three and a half acres, until it is thoroughly seasoned. Moreover, the wood is selected with the utmost care so as to secure not only durability and freedom from blemish, but the most attractive figuring. The booklet includes fully illustrated sections on garden stonework and ornament, and on refinement, taste, and economy in decorative work. The name of the firm being closely associated in the public mind with constructional work, the booklet under notice will do good service in calling attention to their completely equipped decorative and other departments, which include all kinds of stonework, joiners' work, plaster work, sanitary work, and electric lighting.

Artistic Electric Fittings.

Messrs. F. and C. Osler, makers of electric fittings, whose show rooms are at 100, Oxford Street, London, W., and works at 250, Broad Street, Birmingham, have produced an exceedingly fine album in which their designs for various forms of fittings are illustrated by actual photographs, which probably represent the best possible method of showing the exact appearance of the objects. The designs thus shown are without exception artistic in the highest degree, the lanterns,

standards, candelabra, and other forms, having been modelled in accordance with the best traditions of form, proportion, and pattern. The album offers a somewhat embarrassing choice of chaste designs, adaptable to all conditions of lighting and to many idiosyncrasies of taste, ranging from severe simplicity to elaborate decoration. They are, however, without exception charming, each in its own degree and after its own kind, and architects arranging for such fittings should certainly consult this unique album of photographs.

Ferro-Glass for Floor, Roof, and Pavement Lights.

A new system (Keppler's patent) of constructing pavements, roofs (straight and circular), floors, stallboards, partitions, etc., is described and copiously illustrated in a booklet that has been issued by Messrs. J. A. King and Co., of Bridge House, 181, Queen Victoria Street, E.C., who are sole concessionaires for this method of construction. The many advantages claimed for the system may be shortly summarised. In "Ferro-Glass" construction, the maximum degree of translucency is secured. The material surrounding the cement ribs is glass, and is translucent. The

glass being specially constructed, most of the light falling on the plates from below is diverted by total reflection, so that the cement joints remain invisible. Similarly a large number of rays of light falling on the plates from without are no longer lost, but penetrate into the interior of the space to be illuminated, and serve the purpose of lighting it. There is no iron framework to be kept painted or suffer from rust, the steel reinforcing rods being, of course, surrounded with cement. The system is therefore of special advantage in hospitals, or where the atmosphere is charged with acid or other corroding agents. The steel parts which carry the structure, being surrounded by glass and concrete, offer superior resistance to the influences of fire, and, being unaffected by changes of temperature, are not subject to the contraction and expansion which, in the case of unprotected frames, may cause the glass to crack or scale. Tests have proved that the new lights have a bearing capacity of more than sufficient resisting strength for any kind of roof, floor, or pavement light construction. In roof construction under this system, the translucent prisms lie in the same plane as the roof, and do not form any corners or angles in which

WROUGHT-IRON GRILLES (ARMOUR-BRIGHT FINISH) MADE BY
F. AND C. OSLER, LTD.

snow and rain-water could collect and become the cause of leakages; while the roof is strong enough to bear any weight which is likely to be imposed upon it, such as that of a man employed to clean it or to remove snow. In this form of construction the glass prisms and steel reinforcing rods are laid on temporary shuttering at the building, and the joints filled by pouring in the concrete; or the prisms can be assembled at the factory and despatched ready for placing in position. The glasses (which are easily renewable) are made in several colours, and with diamond, prismatic, or smooth underside, and plans can be laid out for any kind of opening.

A list of important buildings at which "Ferro-Glass" construction has been used includes the Houses of Parliament, Somerset House, the Kodak building in Kingsway, H.M. Office of Works, Whiteley's new premises (London, W.), the Sutton Trust Model Dwellings, and many others.

Messrs. Thos. Parsons and Sons' *"Dreadnought."*

At Montgomery's Building Exhibition, which is being held at Rusholme, near Manchester, March 9th to 23rd, Messrs. Thos. Parsons and Sons, varnish and japan manufacturers, 8, Endell Street, Long Acre, London, W.C., have re-erected their interesting and attractive "Dreadnought" stand, as shown at the Building Trades Exhibition at Olympia last year, and more recently at the Crystal Palace at Sydenham. The stand, it will be remembered, represents as accurately as possible the fore part of a modern battleship, with barbette, armoured bulkhead, conning tower, bridge-deck, upper bridge, chart-house, and guns, all complete. The "Dreadnought" is finished in the firm's white "Endelline"; while within the reception-room at the back of the bulkhead are panels showing "Endelline" in various colours, as well as the companion enamel "Endelflat," and samples of "Lacrite," the "Opako" lead-free undercoating, and a few examples of "Trans-ol" friezes, which, as the name suggests, are transfers executed in oil-colour. The stand has not been re-enamelled since it left the hands of Messrs. Trollope, Son, and Colls, who did the painting rather more than a year ago, and it has therefore received only six coats from the bare wood—namely, one coat priming, three of "Opako," one of undercoating "Endelline," and one of finishing "Endelline." Three pantechnicons and two trucks were required to transport the "Dreadnought" from the Crystal Palace to Manchester, and in these circumstances the freshness and brilliancy of the surface are remarkable evidences of the durability of these paints under extraordinarily exacting conditions.

LEGAL.

Builders' Van in Collision: Unfortunate Appeal.

In the Clerkenwell County Court, before his Honour Judge Cluer, an action was brought by George Hammond, chauffeur, of South Kensington, against Francis Charles Ball, builder, of Archway Road, Highgate, for £100, as damages for personal injuries sustained. Mr. A. J. David, K.C., with whom was Mr. Fenton, was counsel for the plaintiff, and Dr. C. Herbert-Smith was counsel for the defendant. This was a new trial. The action first came before his Honour Judge Howland Roberts and a jury on January

8th last, when the jury found in favour of the plaintiff, and judgment was entered for agreed damages, £70. On a subsequent application to the Court by defendant, his Honour set aside the jury's verdict on the ground that it was against the weight of evidence, and another jury was empanelled for a new trial. The action arose out of a collision which occurred on the Uxbridge Road on July 19th last. Plaintiff, who was driving a motor car towards Uxbridge, was passing two coal carts proceeding in the same direction. Coming in the opposite direction were a cart and van belonging to the defendant. Plaintiff said there was plenty of room for him to pass between the two lots of vehicles, but as defendant's van came near to the motor car he noticed the driver jump forward towards the reins, which were hanging loosely. It was alleged that the horse swerved into the motor car and plaintiff was struck in the ribs by a shaft of the van, the shaft penetrating his two coats. He was lifted into the air and dropped into the back of the motor car. Plaintiff was afterwards taken to the Hayes Cottage Hospital, and remained as an in-patient for one month. As a result of the injuries sustained in the accident he was incapacitated for nearly sixteen weeks, and had not yet entirely regained his health.—The jury returned a verdict in favour of plaintiff, and awarded £85 damages. Judgment was entered accordingly, with costs of both trials.

SOCIETIES AND INSTITUTIONS.

YORK AND YORKSHIRE ARCHITECTURAL SOCIETY.

William Etty, R.A., 1787-1849.

On February 28th, before the above society, Mr. A. B. Burleigh, Lic.R.I.B.A., in the chair, Mr. G. W. Milburn, of York, read a paper on the life and work of William Etty, R.A., 1787-1849.

In this lovely old city of York, he said, with its memories and associations, the mind is led backward two thousand years, linking together the early Britons, Romans, Danes, Saxons, Normans, with the citizens of to-day. Landmarks, fine buildings, and written records of men and manners, have been left to us. Illustrious characters, such as Agricola, Hadrian, Constantine, St. Paulinus, St. Wilfrid, and Alcuin for learning; whilst for art the names of Flaxman and Etty stand out conspicuously.

Imagine York without its William Etty, whose name and beautiful pictures are known and appreciated by every lover of choice and artistic work! His fine style of flesh-painting is unsurpassed; and his noble conceptions are of the highest order of merit, and not unworthy, the author thought, to rank with the greatest masters of antiquity.

The son of a York miller, Etty in his youth became a working printer on a newspaper. Etty was 34 years of age when Napoleon died (1821), and the death of such a mighty military genius would appeal to a sensitive nature like Etty's, and in all probability the outcome of his thoughts was the picture of "The Combat" or "Mercy Pleading for the Vanquished." This ranked as the noblest of Etty's productions, and was one of the finest historical paintings that the English school had yet produced.

From his youth he always aspired to be an artist. After serving his apprenticeship as printer on the "Hull Packet," he went to London, to stay with his

uncle; and later was a student at the Royal Academy schools—eventually under Sir Thomas Lawrence.

He thought long in preparation for his pictures, but executed them quickly. He succeeded John Flaxman as R.A. in 1828. He would generally spend the first and second evenings in making a charcoal outline; then go over the sketch with ordinary pen and ink, and then commence to paint. The York School of Design was founded by Etty (it was one of the first provincial schools—1842). It commenced in the Hospitium in St. Mary's Abbey ground, York. He died at York in his 63rd year.

At the conclusion of the paper, a hearty vote of thanks was proposed by Mr. John Windass, F.S.A.M., and seconded by Mr. Harold E. Henderson, Lic.R.I.B.A.

ARCHITECTURAL ASSOCIATION OF IRELAND.

At a general meeting of the above society held in the lecture hall, 15, South Frederick Lane, the president, Mr. Page L. Dickenson, M.R.I.A.I., in the chair, Mr. Conor O'Brien read a paper entitled, "The Development of a National Style of Gothic Architecture in Ireland," which was illustrated by numerous photographs and lantern views of the principal ecclesiastical buildings erected in Ireland between the twelfth and fourteenth centuries. Mr. Conor O'Brien found a precedent for the development of a national Gothic style in the work done in Ireland during the thirteenth and fourteenth centuries, when great originality of design and independence of treatment were shown by the Irish builders. The lecturer also called attention to the excellent carving and workmanship to be found in many of the tombs and memorials to the dead in Irish abbeys.

In proposing a vote of thanks to the lecturer, Mr. R. M. Butler, M.R.I.A.I., suggested as an explanation of the great difference in detail and treatment often to be found in buildings of the same period in Ireland, that many of these buildings owed their erection to the English colonists, and so, naturally, differ in their details and mouldings from those built by the Irish people.

GLASGOW INSTITUTE OF ARCHITECTS.

At the annual general meeting of the Glasgow Institute of Architects, Mr. C. J. MacLean, the secretary of the Institute, submitted the 44th annual report of the Council. This stated among other matters, that the ninth triennial competition for the Alexander Thomson Memorial Studentship was held in February, the subject being a design for a bridge with approaches. The number of competitors was disappointing, only three sets of drawings having been received. The studentship, value £60, was awarded to Mr. James Bennett, Ayr, but in view of the small number of competitors, and the fact that the quality of the work was not up to the standard which the trustees desired, they decided not to award the second prize in this competition.

During the past year the Council had been actively engaged in formulating the scheme for the better regulation of competitions which has now been adopted by the Institute, and in terms of the new Articles of Association the following resolution had been passed:—

"Any Fellow or Associate Member shall be considered to have been guilty of professional misconduct in terms of the Memorandum and Articles of Association."

Association of the Institute, and shall be liable to the penalties therein stated, if it be found by the Council either (I.) that he has knowingly submitted, directly or indirectly, a design in any competition which has previously been the subject of a notice by the Council or by the Committee on Public Architecture and Competitions, prohibiting members of the Institute from taking part in the same; or (II.) that he has knowingly solicited the promoters for permission to submit a design in a limited competition after the list has been closed."

The scheme, which was put before the Institute after long and careful consideration by the Council, is similar to that of the Royal Institute, by which it has been approved. A similar course of action has been adopted by several of the Allied Societies in their respective districts, and the Council is in communication with all those in Scotland toward securing similar procedure on their part where not already in force. The Council hopes under the powers now granted to it to be able to deal more effectively with the apparently increasing number of unsatisfactory competitions.

The president (Mr. J. B. Wilson, F.R.I.B.A.), in moving the adoption of the annual report, referred to the recently instituted licentiate section of the Royal Institute of British Architects. He was pleased to say that the response from their province had been very gratifying, and that from what he personally saw during his term upon the Royal Institute Council, not only in numbers had the Glasgow province been equal to any section of the Kingdom, but in quality also. It was pleasant to know, too, that the Town Council proposed to encourage or assist a Town Planning Exhibition and Conference in Glasgow. The exhibition could be but a shadow of what it might have been had they accepted the offer made them last year, as the bulk of the best drawings were not now available; but it was something to know that at last they recognised that town planning had interests beyond those merely of architects and builders, and that it concerned the municipality and the public most of all. The Corporation having seen the error of their ways in relation to this matter, they might hope for better and saner procedure in other civic matters with which, as architects, they were closely concerned, and in which they had recently ventured respectfully to enter their protest. He referred, of course, to the large and rapidly increasing amount of municipal building work emanating from the City Engineer's Office. At present the Art Galleries, the rebuilding of the historic Tontine, and the extension of the Municipal Buildings—work all calling for high architectural skill—was being, and proposed to be designed and controlled from an "Engineers' Department."

A HAMPSHIRE ASSOCIATION OF ARCHITECTS.

At a meeting of representative Hampshire architects held at Bar-Gate Chambers, Southampton, on March 2nd, Mr. R. F. Chisholm, F.R.I.B.A., presiding, it was decided to form a Hampshire Association of Architects on the lines of those affiliated to the R.I.B.A. Draft rules were considered and passed, as were also declarations to be signed by members, associates, and associated craftsmen, the subscriptions being 10s. for members and 5s. for others.

Sir William Portal, Bart., F.S.A., was elected president; Mr. N. C. H. Nisbett, A.R.I.B.A., proposed by Mr. W. Wheeler, vice-president and chairman of committee; and Mr. R. M. Lucas was elected hon. secretary and treasurer, with Mr. Ingalt

Sanders assisting. Communications from those desiring to join the association should be addressed to Mr. R. Macdonald Lucas, F.R.I.B.A., Bar-Gate Chambers, Southampton.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

On Saturday evening last, at the Royal Court Theatre, Sloane Square, W., an admirable performance of Mr. Bernard Shaw's comedy "You Never Can Tell" was given by that well-known amateur society "The Strolling Players." There was an excellent "house"—due very largely to the efforts of a committee of ladies who worked energetically in the sale of tickets—and we hope that the result will be a substantial donation to the funds of an excellent institution. The object of the Builders' Clerks' Benevolent Institution, it may be explained, is to give relief and to grant pensions to decayed clerks who have been engaged in the building trade of London, and to their widows. This is an object worthy of the support of all connected with building, and we commend it to the attention of our readers. Subscriptions may be sent to Mr. Dudley Bartlett, of Messrs. Perry and Co., Ltd., builders and contractors, Tredegar Works, Bow, E., who at the present time is president of the Institution, and was largely instrumental in organising the performance so successfully carried out at the Court Theatre on Saturday last.

LEGAL.

The Question of Contractual Referees.

In the Court of Appeal, before Lords Justices Vaughan Williams, Farwell, and Kennedy, the Corporation of Bristol appealed from an order in Chambers affirming the order of Master Macdonell, refusing to stay the action of John Aird and Co. against the corporation to recover £171,215 for work done and for damages for breach of contract with respect to dock works at Avonmouth. The contractors claimed £1,927,977, but had been paid £1,753,000, and were seeking to recover the balance. The corporation contended that the matters in dispute should be referred to the arbitrator named in the contract. The Court refused to stay the action.

Vacuum Cleaning: Important Judgment in the House of Lords.

In the House of Lords the judgment has been upheld of the Court of Appeal (which had affirmed the judgment of his lordship Mr. Justice Neville) in the case of the British Vacuum Cleaner Co., Ltd., v. the London and South Western Railway Company. The action was brought to restrain the user of a plant supplied by another company to the railway company; and the gist of the House of Lords judgment is that the British Vacuum Cleaner Co., Ltd., have succeeded in establishing the validity of their Booth's patent (No. 17,433), and that, consequently, an injunction, damages, and costs have been awarded against the London and South Western Railway Company for infringement by use of another plant. It is important to note that the British Vacuum Cleaner Co., Ltd., have instructed their solicitors to take immediate proceedings against any person using any plant which infringes the patent of which the validity has now been finally established in the House of Lords.

IN PARLIAMENT.

(By our Press Gallery Representative.)

The Science and Art Buildings, Dublin.

In the House of Commons, Sir Edward Carson asked the Chief Secretary for Ireland whether it was intended to proceed further with the completion of the original design of the new science and art buildings in Dublin and to erect a façade and entrance from Upper Merion Street; and, if so, why all work on the site had been suspended.

Mr. Masterman, Secretary to the Treasury, who replied, said that work had been stopped in consequence of the completion of the new Royal College of Science buildings. The completion of the original scheme for the erection of new public offices had been deferred in view of the possibility of changes in the requirements of Government departments in Ireland.

Green Park and King Edward Memorial.

Colonel Burn asked for an explanation of the laying down in grass of the recently made gravel walk through the Green Park from Piccadilly to the Mall.

Mr. Wedgwood Benn replied that the walk was being laid down in order to improve the vista from Piccadilly of the Queen Victoria Memorial, accommodation for pedestrians being provided by the construction of two footpaths in the avenues on either side of the Broad Walk. No charge fell upon public funds in respect of this work. He afterwards stated that the work was charged to the Queen Victoria Memorial Fund.

Mr. Lee wished to know whether the change had anything to do with the proposed site for the King Edward Memorial, but Mr. Benn could not answer the question without notice.

Captain Murray wished to know whether any site for the King Edward Memorial other than that at the Piccadilly end of the Broad Walk had recently been under the consideration of the Memorial Committee. Mr. Guest, replying for the First Commissioner of Works, said the answer was in the affirmative. Several sites had been under the consideration of the Committee.

Inspection of Lifts.

Mr. Hildred Carlile asked the Home Secretary whether any regulations were in existence for the inspection of lifts on business premises and in offices; whether the regulations under the Factory and Workshops Act relating to lifts applied also to those premises and in offices; whether he was aware that such regulations were in operation in other countries; and whether, if there were no such regulations, he proposed to take any steps to safeguard the public using such lifts?

Mr. McKenna, in reply, said: There are not, so far as I am aware, any statutory regulations in force in this country in regard to the safety of lifts in offices, nor do they come under the inspection of my Department. I am informed that in some foreign countries regulations on the subject are in operation. Office premises are outside the provisions of the Factory Act, and I am afraid I have no power to take any action in regard to them.

In reply to a further question he promised to take the matter into consideration, but he could not promise legislation this session.

Fair Wage Resolution.

Mr. Keir Hardie has signified his intention when the House goes into Committee of Supply on the Navy Estimates, to call attention to the administration of the Fair Wages Clause, and move a resolution.

COMPETITIONS.

R.I.B.A. Prizes and Studentships, 1913.

The subjects set for the above include the following:—Soane Medallion, A Terminal Railway Station; Tite Prize, The Façade of a Royal Palace in a City; Grissell Prize, A Riding School; Henry Saxon Snell Prize, A Sanatorium for Consumptives. Full particulars are given in the booklet just issued by the Institute (9, Conduit Street, W.), price 3d.

Warrington Competition (Oakwood Avenue Council School), and Blackwood Hall Competition.

With reference to each of these competitions, the secretary of the R.I.B.A. has, by order of the Council, issued the following notice: "Members and Licentiates of the Royal Institute of British Architects must not take part in the above competitions, because the conditions are not in accordance with the published regulations of the Royal Institute for architectural competitions."

Murton Housing Competition.

Mr. J. J. Dobson, of Rodridge, South Wingate, is the successful architect in the competition promoted by the Easington Rural District Council for plans of three types suitable for miners' dwellings at Murton. 129 architects competed. The designs submitted were exhibited at the Council Offices, Easington, from October 25th to January 27th last, during which period the Council met from time to time and considered in detail (with the aid of Mr. William Milburn, architect, of Sunderland, acting as assessor) the merits of the designs. It was not until after this exhaustive consideration, extending over eleven weeks, that the Council finally decided in favour of Mr. Dobson, "whose plans conformed most nearly to the conditions of the competition and to the requirements of miners' dwellings." The estimated cost of the three types is £150, £165, and £200, respectively. The architect is required to undertake the whole of the work in connection with the carrying out of the scheme, and to have an office on the ground, and he will receive 2½ per cent. on the actual cost of the work!

NEWS ITEMS.

Change of Address.

Mr. H. Ascough Chapman, F.R.I.B.A., Architect, has moved from Leeds to Cantelupe Road, Bexhill-on-Sea.

Partnership.

Messrs. E. A. Roome and Co., builders and contractors, of 36, Basinghall Street, E.C., have taken into partnership their manager, Mr. F. J. Gayer. The title of the firm will remain as before.

Old Birmingham.

The offices of the Birmingham Canals and Navigation, at the corner of Broad Street and Suffolk Street, are to be demolished shortly, to make way for some new business premises.

Buttresses for Winchester Cathedral.

In response to a wish expressed by a number of Wykehamists, arrangements have been made with the Dean and Chapter of Winchester that one of the new buttresses on the south side of the cathedral shall be the gift of Wykehamists and those connected with the College, and shall be named the Win-

chester College Buttress. The buttresses are all required largely in order to preserve Wykeham's magnificent work in the nave; and the buttress selected is one of the two on which the Shrine of the Founder in some measure rests.

Condition of the Galilee Chapel at Durham Cathedral.

The condition of this chapel, which is at the west end of the nave, and is probably the most beautiful example of Transitional Norman architecture existing in England, is stated to be unsafe.

The King of Italy and the British School at Rome.

Dr. Ashby, the Director of the British School at Rome, has been received in audience by the King of Italy, to whom he presented an album containing forty facsimiles of drawings of Roman scenes, by British artists, from the print room of the British Museum. The dates of the drawings ranged from 1715 to 1843.

Old Town Hall, Manchester.

The Manchester City Council approved last week the action of the Parks Committee in agreeing to the proposal to remove and re-erect in Platt Fields the colonnade and wings of the old Town Hall in King Street. The Committee propose to make a request to Lloyd's Bank, who have bought the old building and its site, to present to the Corporation the stonework, comprising the colonnade and wings, containing statuary.

Internal Decoration of His Majesty's Theatre, Manchester.

Messrs. John Tanner and Son, of 45, Horseferry Road, London, S.W., and Liverpool, have been entrusted with the whole of the fibrous plasterwork and decorations for the new His Majesty's Theatre, Manchester, the architects of which are Messrs. Horace Farquharson and Richardson and Gill. A perspective view of the interior was published in our issue for December 27th last.

Art Museums and Picture Galleries.

Mr. Edwin T. Hall, F.R.I.B.A., will read a paper on "Art Museums and Picture Galleries" at the general meeting of the Royal Institute of British Architects fixed for April 1st. The illustrations will include a fine collection of slides specially prepared for the paper. Mr. Hall's paper is in substitution for that on "Modern Methods of Construction," which Mr. Dunn is unable to read.

The London County Hall.

The King, accompanied by the Queen, Princess Mary, and the Prince of Wales, laid, on Saturday last, the foundation-stone of the new County Hall for London. A silver trowel, specially made by students of the Council's Central School of Arts and Crafts, was handed to His Majesty by Mr. Ralph Knott, the architect. Afterwards the King conferred the honour of knighthood on Mr. Edward White (Chairman of the Council) and Mr. Maurice Fitzmaurice, the Council's chief engineer.

The New Adelphi Hotel, Liverpool.

This new hotel, part of the rebuilding scheme of the old Adelphi, is to be opened on March 26th. It is claimed to be "one of the finest, if not actually the finest, in Europe." The grand ballroom, the French restaurant, and other spacious apartments are designed on a scale of

unusual magnificence, while the Hypostyle Hall, opening on to beautiful gardens, will be a revelation of what can be accomplished both architecturally and decoratively. About 1,000 workmen are constantly engaged on the building, and the work is being rapidly pushed forward towards completion. Members of the Liverpool Architectural Society recently paid a visit of inspection, when they were shown over the building by the architect, Mr. R. Frank Atkinson, F.R.I.B.A.

The A B C Railway Guide.

The March issue of the "A B C Railway Guide" shows a further enlargement and is reset in new type. The Guide gives train information for every station in Great Britain, with distances and fares to every station where there are through bookings, and the positions of the stations are shown on the revised maps by reference numbers. The Guide contains over two thousand names of the principal hotels and boarding establishments in England, Scotland, and Wales.

Fire-resistance of Reinforced Concrete.

A fire test on a large scale has occurred at the Blabon Oil Cloth Works in Philadelphia. A four-storey concrete building with wired glass skylight was used as a drying plant for long strips of linoleum, which hung down from iron bars at the top. There were no floors in the building, which was practically a shell. The linoleum caught fire and burned up, but the building was uninjured, although the fire is reported to have lasted several hours.

A Trade Proposal.

The well-known joinery works of Messrs. Samuel Elliott and Sons, Ltd., of Caversham, Reading, have been carried on for the last three or four months by a receiver and manager, and we understand that the large staff of skilled workmen have been working overtime in order to cope with the orders in hand. We are requested by the Receiver to state that he is prepared to enter into negotiations for the amalgamation or purchase of the concern, and could probably arrange to finance a considerable portion of the purchase price. Enquiries should be addressed to the Receiver, Mr. Sydney W. Tubbs, F.C.A., 28, Basinghall Street, E.C.

The Law Union and Rock Building.

On Saturday last, Mr. Howell J. Williams, the contractor for this building (which is now being completed on a site next to the Records Office in Chancery Lane, London, W.C.), gave his men who had been mainly responsible for the interior fittings an opportunity of seeing the finished work in its place. Mr. Williams, in a short address, said he considered it was a happy thought that suggested this idea, and he regretted that it had never struck him before, but hoped he would have many similar opportunities in future. Mr. Williams mentioned that he himself had once worked at the bench, and had had to start at six o'clock in the morning. The young craftsmen and artisans of the present day who wanted to rise, he said, must take an intense interest in their work, as he did; and he recommended them to make the fullest possible use of the abundant facilities for technical education which were now available. Mr. Williams mentioned that a quantity of eighteenth-century brickwork, found on the site, had been incorporated in the new building.

Cheap Cottages.

CORRESPONDENT of the "Spectator," who we gather to be a large owner of landed property, raises a new point with regard to the possibility of providing cheaper cottages on country estates than can be furnished by the means and materials in general use. He bases his letter on the fact that the Board of Agriculture

has appointed a Departmental Committee "to enquire into the nature and character of buildings which should be provided for use in connexion with small agricultural holdings in England, with special consideration as to the possibility of the reduction of cost, by the use of materials and methods of construction different from those ordinarily employed at present."

As the correspondent in question, Mr. H. B. M. Buchanan, says (and we entirely agree with him), the enquiry is a most important one, since in providing small holdings the great point is to avoid all unnecessary expense in building operations. And Mr. Buchanan's main suggestion is that wooden buildings should be more largely used. That out-buildings should be built of wood, on brick foundations, is of course easily agreed to; his suggestion is that we should turn our attention more to the possibilities of wood structure for dwelling houses. He mentions, naturally, the extensive use of wood dwellings, what are called in America "frame houses," in the country districts of the United States and Canada. These have formed a special department of American house-building; but our impression is that, whether for good reasons or not, they are rather beginning to fall into disfavour. It is certain that we hear much less about them now than we formerly did.

The kind of cottages recommended is one of which the exterior of the walls is formed of boarding tarred or creosoted from time to time, with strong angle posts of hard wood, all on a brick foundation; this outer face being backed (we presume that is what is intended) with a certain thickness of lath and plaster; but the precise method of lining them is not very distinctly specified. That such cottages could be built very cheaply is obvious enough. The social importance of the subject lies in the consideration that in order to keep people on the land it is necessary to have houses ready for them. When labourers once drift into the cities, they do not come back. On Mr. Buchanan's own estate there are, he says, more than the average number of cottages; "yet when any of the young men wish to marry they will have to leave the estate and seek work elsewhere, probably in the towns, because I shall have no vacant cottages to offer them"; and the conclusion we suppose is that he cannot afford to build more by the ordinary methods.

Thus the question of cheap cottages touches the very existence of agricultural life. Can we regard the method suggested as a practical and satisfactory one? We feel somewhat doubtful about it. The editor of the "Spectator" blesses the scheme entirely, and states that on an estate of his own, in a very exposed situation, the winter rains penetrated through hollow brick walls; through ordinary

brick walls covered with rough-cast; through walls of cement blocks partially hollow; and that the tarred boarded cottages were the only ones that kept the wet out. We should have liked to inspect these various buildings before forming an opinion; it is a good deal a question of how the brick walls were built, especially the hollow ones, and of what kind were the cement blocks. We cannot quite take the editor of a political and literary paper as an expert on building. He says that the idea that wooden houses are not fit for human habitation in this climate "is the greatest of delusions." Our experience does not bear that out quite. The wooden cottages of the kind he describes may have kept rain out, but will they keep frost out? The writer of these words has twice stayed in old-fashioned half-timber farmhouses (let as holiday lodgings) during frost, and did not enjoy it. His experience was that the temperature inside was very nearly as low as that outside; in the morning it was like getting up in the open air.

That the danger from fire in a country district, where buildings are not packed up to one another as they are in towns, is almost negligible, we agree. Such houses would be all plaster inside, and plaster is a very good fire-resisting substance. We heard only a few days ago of a remarkable instance of this, in the case of an early nineteenth-century church, the arcade of which, with the spandrel surface above it, was formed of plaster mouldings and wall-surface on a timber framing. The church was burnt, and in the course of the conflagration the fire penetrated from above the arcade into the timber backing, which was all burnt away, but the plaster shell was left nearly uninjured, standing by its own adhesive power. So that we do not think the danger of fire need be much regarded. But that these wooden and lath-and-plaster walls will be efficient protection from the cold of a hard frost we do not believe.

The question of appearance, though no doubt a secondary matter in such a case, counts for something. One can hardly imagine anything less inviting in appearance than black tarred wood cottages, nor is the smell of tar or creosote, which must be renewed from time to time, very agreeable. If the object of building cottages is to keep the labourers on the land, it is important to consider whether they will be willing to live through the winters in wood and plaster cottages. We should rather doubt it.

The editor of the "Spectator" does not say whether he tried hollow walls with rough-cast facing; as we read it, the rough-cast was only applied in the case of the solid brick walls. Rough-cast and hollow walls combined might have done the business in keeping out the rain, though we are not very much in favour of hollow walls; one never knows what may be accumulating in hollow spaces that can never be inspected.

No mention has been made in the correspondence of concrete, which might be a more efficient way of providing cheap cottages than that suggested—at least, in neighbourhoods where the materials for concrete are within easy reach. It depends a good deal upon that. Concrete is cheaper than brickwork where the materials for it are at hand, but not otherwise.

The wooden cottage suggestion may be worth consideration and experiment; but for the reasons above given we rather doubt of its success.

Mr. Ralph Knott and the London County Hall.

WE publish on this page a new portrait of Mr. Ralph Knott, the architect of the London County Hall. He is one of the young men of ability who have been discovered through the open competition system, and though only 33 years of age is now engaged on the largest building in course of erection in this country. Mr. Knott was educated at the City of London School. At the age of 17 he became articled to Messrs. Woodd and Ainslie, architects, of Westminster, with whom he stayed three years. He subsequently entered the offices of Sir Aston Webb, and it was when there that he gained the London County Hall competition. This, however, was not his only competition success, for he had previously been placed second for the Bristol Central Library, and had gained a similar place in the competition for the new library at Malvern.

The mallet, plumb-rule, and level illustrated on the opposite page were used in connection with the laying of the foundation-stone of the London County Hall by His Majesty the King on March 9th. These were made by the Bromsgrove Guild, who also executed the bronze casket in which the coins and documents deposited in the foundation-stone were placed.

For the accompanying plan we are indebted to "The Surveying and Housing World."

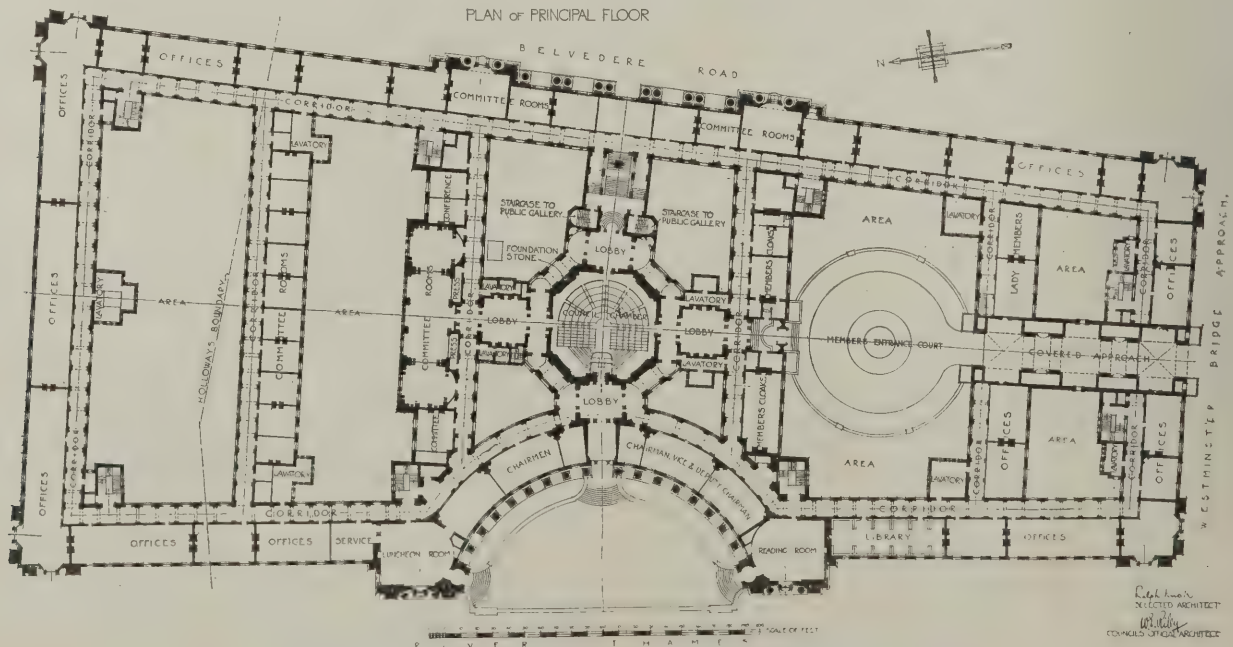

London Street Name-Plates.

THE method or want of method in the display of the names of streets in London has long been a discredit to us. The Institute of Architects have taken the matter up, and have invited a conference of representatives of the various borough councils to consider the subject; and we believe that this invitation has in most cases been responded to in a friendly spirit. It appears to us that there are three main points for consideration in connection with this subject. The first is, the necessity of having the naming universal, at the corners of all streets. At present this has been most capriciously done; there are numbers of streets in London in which one can find no name till after going some distance along the street. Such carelessness is absurd, and is the occasion of serious public inconvenience. In Paris, the names are at every street corner, and there is no reason why they should not be so in London, except that of indifference and neglect on the part of borough authorities. The second requirement should be uniformity in design and lettering. At present the name-boards are of all kinds of material and design; a fact which does not speak of a well-governed city. And when we say uniformity, we mean uniformity over the whole of London. Some of

MR. RALPH KNOTT. Photo: Hoppé.

the borough authorities seem possessed with the idea that each borough should have its own distinctive name-plate, to be used within its own jurisdiction. The obvious objection to this, which will occur at once, is that in some cases the borough boundary runs down the centre of a street, and then the two name-plates would differ on opposite sides of the street. But independently of that objection, it is far better for appearance and convenience that all London streets should be named and lettered in the same manner; there is no sense or advantage whatever in having so many different designs of name-plates in the different

THE LONDON COUNTY HALL: PLAN OF PRINCIPAL FLOOR.

boroughs of London, especially as in that case they will certainly not be all equally good. Let the best possible one be selected, and be introduced for the whole of London. The desire of borough authorities to have their own special lettering is a kind of vestryman's policy, narrow-minded and egotistical. Thirdly, we want to see a really well-designed but perfectly legible lettering, in a form and material that will be durable; and of course it must not be too costly in either material or method of construction. No doubt specimens will be produced and discussed at the proposed conference. Probably the best material, for combining economy with appearance, would be cast-iron plates with the lettering in relief; in that case the lettering can always be painted up by an ordinary painter, without requiring the employment of skilled labour. Letters flush with the general surface of the plate, in whatever material, are apt to get soon dulled in a smoky atmosphere.

Greek Sculpture.

IN the paper on "Greek Sculpture" which he read before the Royal Society of Arts last week Professor Ernest A. Gardner dealt with the conditions in which the Greek sculptor worked and attained to such extraordinary excellence. To enable these to be realised, he first discussed at length the very different conditions in which we view the examples of the art that have come down to us. The disadvantage of seeing these examples out of their natural setting cannot be overcome. If the Elgin marbles, for example, were restored to Greece they would still, he said, be shown in a museum in Athens. To replace them even in a reconstructed Parthenon would expose them to damage from weather, and the protection of such monuments is above all imperative. So also, in respect of restoration, the negative rule as surely holds; and not only must we be content with imperfect statues, but we must also remember that originally they were coloured. And, finally, in judging Greek sculpture, it is necessary to distinguish between originals and copies, and in particular to differentiate between Greek copies and those of Roman date. Having thus shown the main calls upon our imagination if we are to see their sculpture as the Greeks saw it, Professor Gardner rapidly sketched the conditions in which the Greek sculptor worked, and the marvellous freedom and renewal of impulse which he enjoyed within the convention of a few limited types. In this part of the lecture especially he was greatly aided by the excellent illustrative photographs thrown upon the screen.

Bell-Frames in Church Towers.

THERE has been a discussion going on in a Cambridge paper as to the merits of the modern iron frames for hanging church bells, as against the old wooden frames. The Secretary of the Society for the Protection of Ancient Buildings has been upholding the wooden bell-frames of the old type, but in doing so he is, we think, rather acting against the protection of ancient buildings. There is plenty of evidence that the more scientifically constructed modern iron bell-frames are more efficient in keeping strain off the tower walls than the old and often badly constructed timber frames; and the Vicar of Longstanton, who from his letter is evidently an expert in bell-ringing, asserts from his own experience that the bells can be rung more easily and with less effort in the modern frames. The only objection that we can see to the iron frames is that the fact of being hung in iron instead of in wood may to some extent affect the tone of the bells, not for the better. This is, of course, denied by the iron-frame advocates, but we should think it must make a difference, though perhaps not so marked as to be detected by those who were not on the look-out for it.

The Architect and the Public.

THAT entertaining writer "The Londoner" in the London "Evening News" has delivered the retort courteous to the architect who, in a recent paper at the Institute of Sanitary Engineers, was engaged in the time-honoured assault on the Public for its ignorance of architecture. In this matter the professional man is usually talking to his professional brethren, who, naturally, are ready to back him up against a common object of taunt. No harm is done, because the object itself is almost sure never to hear of the diatribes, and, even if in some instances it does, has rarely the capacity to reply effectively. But there are two sides to all things, and we feel grateful to "The Londoner" for coming on so merrily. The lecturer in question appears to have inferred that artists and musicians have all the luck, that everybody knows their names, and they are part of every talker's stock-in-trade. Yet, said he, nine people out of ten did not know who designed the Houses of Parliament, the Roman Catholic Cathedral at Westminster, St. George's Hall or Liverpool Cathedral, Waterloo Bridge or the Bank of England, not even the Banqueting Hall in Whitehall. The answer to that statement we must leave to the incisive writer. He says: "No doubt it is all

PLUMB-RULE, LEVEL, AND Mallet USED IN LAYING THE FOUNDATION-STONE OF THE LONDON COUNTY HALL.

very true. Or, let me say, there is a deal of truth in it, in any indictment for wilful ignorance which you may draw upon against the Public. Take us in the lump, we are an ignorant lot. Indeed, I am disposed to think that this architect, for all his harsh words, is very subtly flattering us. Let me, as one of this miserable Public, cheer myself up by putting the same case the other way round. Never mind about the nine out of ten; take the one which remains after subtracting the nine. Is it indeed possible that one in ten of us, that a hundred out of a thousand of us, know all about Sir Charles Barry's work at Westminster, and how he came to make Gothic designs so curiously in the manner of young Mr. Pugin? Is it true that one in ten of us has the story of Sir John Soane by heart, an affectionate memory of Sir John Rennie and Byzantine Bentley, with a lively appreciation of that wonderful young man Mr. G. G. Scott? If so, the Public should be reasonably proud of its average intelligence. As one of it, I am in the mood to charge back on our critics. Can the Architects themselves, not to speak of the Sanitary Engineers, show such a fair level of liberal knowledge? Are ten in a hundred F.R.I.B.A.'s and A.R.I.B.A.'s sound in the Elizabethan dramatists: will at least one out of ten sanitary engineers write me down a dozen lines of Kubla Khan or Herrick's song to the daffodils without material error? The truth is that we all, even the Sanitary Engineers and the Architects, have our fair share of ignorance. . . . All things being considered, the architect has no good reason for complaining. It is true that the fame which is publicity or notoriety helps the poor fellow to a meagre portion. Yet he has it among his fellows. They know who had the cathedral job and who was chosen to build the town hall, and, as I suppose, they crown the victor with laurel and rejoice with him in Institutes, giving him praise and blessing. If so, the Architect should be well content. . . . But should he, even though his ignorance of Kubla Khan be complete? We think that what the lecturer had in mind was, that the architect did not receive the tribute which is due to him when he creates a very notable addition to a city's buildings. The foundation-stone ceremony generally furnishes an

excellent example of this, for it is then customary to record the presence of every official, to set out the details of a hundred trivial matters, while not making a single reference to the architect whose ability has created the whole design. He may not be a seeker after publicity, but he should at least get his proper share of recognition.

Passing Crazes in Domestic Architecture.

ONE needs to be well on guard against some craze that are sweeping through English domestic architecture, more especially as they have been adopted by certain designers of ability. One of these is the craze for small low rooms. This is part of the notion that if we can only live like the old cottager did, we shall be well on the way to gain "simplicity" in a world of extravagance. And so we have the rather pitiful spectacle of an ordinary commonplace Briton sitting, rather forlorn, in a low room with exposed beams, and only wanting the dangling hams to prevent his standing up straight. All of which arises from the mistaken notion of applying seventeenth and eighteenth-century surroundings of an agricultural character to a modern man who has very little in common with the country. The same thing is often seen in the case of windows. So entranced has the sketcher become with the honeysuckle-entwined lattice of the country cottage or the small farmhouse that he rushes to repeat it in his modern creation, but probably his house is in quite alien surroundings, sunlight and air being shut off by streets of neighbouring houses; and even if it were not so, and the conditions were the same, there would be the difference between a burly countryman living the whole day in the outside air and a pale city dweller of sedentary habits. Another craze gives us the brickwork fireplace. In some great room, with plain tables and walls, sturdy and rough in keeping, such a fireplace is delightful; but when we put it in a room where nothing else is similar, it becomes ludicrous. We are asked to suppose that it is quite proper, and admirable, after sitting at the Sheraton table with finely cut glass and all the appointments of cultured elegance, to forgo round this crude piece of brickwork, whereon maybe, are set delicate silver candlesticks and choice examples of china. The whole thing is incongruous, and the sooner we have done with it the better. If we would have the brick fireplace, we had better forswear our trap-pings and live up to it, in corduroys, with a rough table and platters—and no such things as books bound in soft leather! It is all the art of make-believe, in a very polite way. The garden city has furnished us with plenty of examples, both inside and out. And, referring to the outside, we recall the attempts at living the simple life in a garden plot a dozen yards square, with green smocks and ever the delight of the artistic coterie; and as the evening sun sinks we, sitting in the oak porch (6 ft. by 3 ft.), may imagine we are gazing at the everlasting hills instead of a similar creation to our own on the other side of a 20-ft. road.

A Mistake of £1,000 in Tendering.

AT last week's meeting of the Bangor Guardians a curious mistake was reported. The Chairman stated that at the previous meeting the tender of the Todmorden contractor had been accepted for the erection of the new workhouse infirmary at Bangor. After the contract was told that his tender was accepted he was asked for information in order to enable the Guardians to fill in a form required by the Local Government Board. He now informed the Guardians that when searching for the particulars he discovered that a clerk in his employ had made a mistake of £1,000 in his tender, and he forwarded the paper showing how the error occurred. It appeared that the mistake took place in adding up the total sum. A long discussion occurred as to whether the contractor should be invited to tender again, and it was eventually decided to invite him, with all the others who had tendered, to re-tender, which was undoubtedly the best way out of the difficulty.

FOOT OF STAIRCASE, CHÂTEAU DE CHANTILLY.
THE LATE H. DAUMET, ARCHITECT.

THE S.A.D.G.

IN France the letters S.A.D.G. are as familiar to architects as the letters R.I.B.A. are to the profession in this country, as they stand for that influential body, the Société des Architectes Diplômés par le Gouvernement. Last year the Society registered its thousandth member, and celebrated the occasion by the publication of a fine volume of about 60 plates, illustrating the work of its leading representatives, a copy of which publication was presented to the Royal Institute of British Architects, and is now to be seen in the Library at 9, Conduit Street, W. Five of the plates are here reproduced to a small scale. They are, perhaps, as good as any others in the volume, though this includes a certain number of examples that possess little merit—in fact, the domestic designs generally are of an extremely poor character, strangely in contrast with the good taste shown in the civic work. But, taking the collection as a whole, it is a most admirable one, testifying to the worth of modern French architecture. While looking through it one may imagine what would be the collective value of a similar publication illustrating buildings by living members of the R.I.B.A. Without doubt there would be individual examples of great merit, but the general level of the work would certainly be far lower than that shown in this volume of the S.A.D.G.

In connection with the accompanying illustrations some account of the Society may be given.

First let it be stated that the Diploma, the distinctive mark and stamp of a qualified architect, was long sought. In 1843 the Central Society of French Architects endeavoured to ascertain what measures could be demanded from the Government to remedy the defect of anyone being able to call himself an architect and to practise as such. Three years later, in 1846, a commission declared for a compulsory diploma. The Government of Louis Philippe made several proposals with this object in view, but before anything definite was sanctioned the administration collapsed. In 1863 a decree for the reorganisation of the Ecole des Beaux-Arts was issued, and at the same time the protest of the Central Society of French Architects was taken up again, with the result that four years afterwards, on November 27th, 1863, a ministerial resolution instituted the Diploma. Administrative difficulties, however, arose from the very beginning, and it was only through the foresight of M. Eugène Guillaume, then Director of the Ecole des Beaux-Arts, that the Diploma was able to take a definite form. "Having to control the Architectural Section," writes M. Guillaume, "I did not experience much trouble in making the Administration understand that the instruction provided at the school was not to produce Prix de Rome, but architects; at the same time, before an architect commenced to practise it was necessary that he should have before him some proof to show that he had gone through a complete course of study. In brief, I asked that a new title should be instituted by the school, as an encouragement to work, as a guarantee of ability, and as an indemnification. This title was the Diploma." Such a title was granted, and then, in the early days of its existence, there began a fierce attack from without, by those who regarded the scheme as a mere school affair divorced from practice, and by those—Viollet-le-Duc among them—who were opposed to what they considered to be, not a professional guarantee, but the establishment of an official clique. However, the Diploma, though young, had plenty of vigorous supporters who did not fail to come forward,

MAIN ENTRANCE TO THE MUSEUM AT NIMES.
MAX RAPHEL, ARCHITECT.

and later a committee of influential members was formed to put forward the important request that holders of the Diploma should be employed for State works. There was no lack of opposition to this proposal also, but it was eventually carried. We now come to 1881. In that year the holders of the Diploma, numbering forty-four, assembled together for the purpose of considering the founding "of a society of purely friendly character, non-official, holding an annual dinner, electing a committee annually, and paying a fee of 5 francs per member." Such a society was then brought into being, and their first success, the appointment of one of their members, M. Jasson, as architect to the City of Nancy, was heralded with joy. This was certainly an advance, but the opposition to the Diploma still found voice, and trouble continued. However, matters improved little by little, and by the year 1890 it may be said that the Diploma was firmly established. From that time its progression has been steady, and to-day it is recognised as the highest mark of distinction in the profession. It is not obligatory, but furnishes evidence that holders of the Diploma have had a regular training in the Ecole des Beaux-Arts, and are to that degree qualified architects. Portraits of four leading members of the Society are here reproduced. M. Pascal, now in his seventy-fifth year, is the *doyen* of French architects, and has many fine buildings to his credit, including the additions to the National Library, Paris, the Faculty of Medicine and Chemistry at Bordeaux, and monuments to Regnault, Michelet, and Victor Hugo. M. Nenot was the architect of the new Sorbonne, M. Ch. Girault of the Petit Palais, and M. Laloux of the Gare d'Orléans, Paris.

THE DAWN OF THE
FRENCH RENAISSANCE.*

BY W. H. WARD, M.A. CANTAB., A.R.I.B.A.

NO country outside of Italy made the teaching of the Renaissance in architecture so thoroughly her own as France. In Italy this attempt to express contemporary requirements in a language of forms and proportions inspired by the study of ancient monuments was a native growth, a reversion to national methods temporarily disturbed by foreign importations. The causes which led to so ready and complete an acceptance of it in France, which had a native architecture of an altogether different character, form too wide a subject to be discussed now, if time is to be left for a survey of its consequences.

In the fifteenth century, France rose from the anarchy and disorganisation of the Hundred Years' War to a new era of prosperity and consciousness of national life under the rule of a strong monarchy. This state of affairs found expression in the last or Flamboyant phase of her Gothic architecture, characterised by extravagant but graceful exuberances, immense technical dexterity, and excessive naturalism in sculpture. The bulk of the buildings of the time showed an intricacy of decoration and restlessness of line hitherto unreached. But signs were not lacking here and there of a striving after those ideals which everywhere

accompanied the Renaissance—the change from the striving and aspiring, the vertical and the mysterious in architecture, to repose, horizontality, and clarity. The elaborate tracery of the screens at Albi shows a return to the semicircular arch, and the courtyard of the house of Jacques Cœur at Bourges displays a tendency to horizontal treatment and regularity of setting out, though both works are wholly Gothic in detail. The way was thus being imperceptibly prepared for the great change to come. Definitely Classical detail first made its appearance in certain monuments carried out by Italians about 1480, under the auspices of the House of Anjou, which was closely connected with Italy—a chapel in the old Cathedral of Marseilles, tombs at Le Mans and Tarascon, a reredos at Avignon. They do not seem, however, to have made any impression on the French building profession, and during the following fifteen years the movement was at a standstill, till the enthusiasm for Italian art aroused in the minds of the French King and his Court during Charles VIII's campaign of 1495 set it going once more. Italian craftsmen of various descriptions, stone and wood carvers, painters and majolica workers, cabinet makers, bronze-founders, and garden designers were engaged to work in France. Close intercourse with Italy was kept up for the next thirty years by the foreign policy of the succeeding reigns, and the almost incessant wars in different parts of Italy which it involved. During this period troops of Italian craftsmen spread throughout France, the valley of

the Loire, Normandy, the Ile de France, and the neighbourhood of Toulouse being the chief centres of activity. The result of their presence manifested itself at first principally in the appearance of ornament and detail, occasionally of entire features in the Italian manner, in buildings otherwise of a Gothic character, such as the wing added to the Castle of Châteaudun in the first years of the sixteenth century [shown on the screen]. The same mingling of motives is seen in individual features such as the chimney-piece from the same building.

By the time Francis I. came to the throne on January 1st, 1515, Renaissance forms had become acclimatised. Though Italians were still frequently employed, the French builders had acquired some skill in the new style. The result was that a number of buildings began to arise which have been characterised as French construction in Milanese dress. The well-known example of Francis I.'s work, the Château de Chambord, is a case in point. The castle plan, the moat, the round towers, the spiral stair turrets, the steep roofs, the 'chemin de ronde,' the picturesque and irregular sky-line, are essentially French; but the pilaster treatment of the elevations, the decoration of the dormers and chimney-stacks, and the detail and ornament throughout, are drawn from the repertoire of the North Italian Renaissance, so like in its exuberance to the native Flamboyant Gothic, while the soberer work of Brunelleschi and the early Florentines, and of Bramante in his Roman manner, found little

FACULTY OF MEDICINE AND CHEMISTRY, BORDEAUX. JEAN LOUIS PASCAL, ARCHITECT.

echo at this period in France. The qualities which charm in this style, the style of Francis I., as it is called, which prevailed roughly from 1515 to 1540 or 1545, are its picturesque and somewhat haphazard grouping, its ingenious use of Italian motives to clothe native building forms in a delicate embroidery of ornament, as in the entrance bay at Azay-le-Rideau [shown on the screen], or in the great staircase at Blois. This reproduces the mediæval type of which the classical example was the staircase of the Louvre built by Raymond du Temple in 1365, while the adjoining cornice is a reminiscence of mediæval machicolations. The style is lovable, too, in the interior, where its rather minute scale is more appropriate, and where the fineness and variety of its exquisite arabesques can be more fully appreciated.

The middle years of the sixteenth century in France were a period of intense intellectual and artistic life, when amongst other activities Italian literature and art as well as classical studies were cultivated with enthusiasm, and, in every department of life, refinement was pushed to its furthest limits. The court and upper classes generally were both prodigal and discriminating in their patronage of all branches of art, and in particular in the building of splendid residences.

From this time onwards arose a new generation of men whose training was theoretical as well as practical, men like Philibert de l'Orme, Jacques Androuet du Cerceau, and Jean Bullant; men who read and travelled, and in some cases visited Italy and sketched and measured

buildings there. This brought about one side of the change. The other was due to the new sources of inspiration; for both the young French architects and the Italians whom Francis continued to attract to France were now imbued with the ideas of the mature or Roman phase of the Renaissance.

The effect was soon seen in schemes considered as a whole from the start, in a broader manner, a greater regularity and symmetry, in a more systematic use of the orders and a more scholarly treatment of detail, as well as in the shedding of much mediæval practice, particularly such as related to fortification. At the same time much that was both national and picturesque was retained. Round towers and spiral stairs, oriels and turrets, steep gables and flying buttresses, crockets and finials and open crestings, and the delicate arabesque decoration of surfaces fell into disuse. On the other hand the large mullioned windows and tall dormers and high-pitched roofs—one pitch to each block—remained, and the vertical character of design was thus maintained in elevations, as well as by the frequent rectangular pavilions, which replaced circular towers. There had thus been evolved an architecture which, if it still bears upon it both the faults and the charm of youth, may yet be regarded as having reached the first stage of maturity.

France, then, within the middle years of the sixteenth century had arrived at a style based on the Classic code of forms and composition, which suited her then requirements, and which eventually

proved susceptible, by a process of relatively small successive modifications and adjustments, simplifications or elaborations, of adaptation to the changing conditions of social life up to the Great Revolution. It was perhaps the more fitted permanently to satisfy a variety of French requirements in that the foreign element in its composition was itself of a twofold nature. The mature Renaissance was introduced from Italy at a time when it was already beginning to bifurcate into the twin-stream of Michelangellesque Baroque and puristic Palladianism.

A type of plan for the great house in town or country had by the time of Henry II. been evolved from that of the mediæval castle and became fixed for succeeding centuries. This is true, however, only of the general outline and massing, for changes in the habits of social life were to call for many modifications in the internal arrangements from time to time. In essence this plan consists of buildings surrounding an enclosed rectangular courtyard with the main block at the back, a screen in front containing the entrance, while the sides were either extensions of the main block or lower galleries. At each angle of the court was a rectangular pavilion somewhat higher than the adjoining buildings, with occasionally a pavilion larger than the rest in the centre of the main block. Subsidiary courts were also added on various sides, such as garden courts, forecourts, kitchen, and stable-courts. The tendency was for the main block to grow in importance at the expense of the remainder, becoming deeper and receiving pavilions

at each angle. The court came to be enclosed by nothing more than balustraded terraces, railings, or even merely lines of trees, while the moat, wet or dry, which enclosed the main court, persisted at least in occasional use down to the Revolution, as also did the wholly or partly detached pavilions at the angles and entrance of the Court.

If, besides the plan, we examine many of their features specially associated with a particular style we shall find that they were already present at least in embryo in the sixteenth century. The characteristic high-pitched roof derived from the Middle Ages never at any time up to the present day ever went out of use, even in the most classicising periods. It is a striking fact, for instance, that at Versailles itself the chapel which so sadly mars the symmetry of the palace is the only executed part of a scheme to re-roof the whole vast building with high roofs. Again, two forms of steep roof so characteristic of French practice in the seventeenth and eighteenth centuries, the so-called Mansard roof with its broken slope, which every schoolboy knows—and knows wrongly—to have been invented by François Mansart, had already been employed by Lescot at the Louvre, and the curved hipped roof or square dome familiar at the Pavillon de Sully, the Palais de Justice, and elsewhere, occurs frequently in the drawings of Jacques Androuet du Cerceau. Further the flat balustraded roof so often censured as a fad of the age of Louis XIV. occurs as early as in Francis I.'s building at St. Germain.

Again, the brick architecture with rusticated stone coigns and bands typical of the reign of Henry IV. is foreshadowed in some of the designs for Charleval illustrated by Du Cerceau and in the outer pavilions at Anet by Philibert de l'Orme; and persists as late as the Chateau of Ménars built by Madame de Pompadour about 1760; while the accompanying feature of windows grouped in vertical lines by coigns or pilasters is traceable not only to the style of Francis I.—we have seen an instance of it at Blois—but to late Gothic buildings, as, for instance, the episcopal palace at Evreux. Much the same may be said of decoration as of architecture. All later styles of decoration in France derive much, if not all, from the stock of ideas already possessed by France in the Middle Ages or acquired by the time of Henry II. Not to multiply unduly, I may instance one detail of ornamentation usually associated with the Louis Seize style—the oval medallion over which a garland with pendent ends is draped—as occurring as far back not merely as 1665 on Perrault's Louvre but as 1565 on Lescot's Louvre.

Renaissance architecture in France may thus be said to have reached in the mid sixteenth century a stage of at least incipient maturity, not only as regards the character of its buildings *per se*, but because it already contained, either in germ or fully developed, nearly all the elements which went to the making of subsequent styles.

The author illustrated the further progress and development of the Renaissance in France by describing the influence of the revival of classical studies in the seventeenth century, and the work of Salomon de Brosse, the Mansarts, Louis le Vau, Jacques Ange Gabriel, and other makers of the Renaissance, due attention being given to the details of the interior design and decoration, as well as to the developments of style in the elevations.

THE NEW KING'S COLLEGE HOSPITAL.

The site of the new King's College Hospital at Denmark Hill, which was the objective of the fifth spring visit of the Architectural Association on Saturday last, comprises about twelve acres, and was presented by the Hon. W. F. D. Smith, the chairman of the Hospital Committee.

The urgent needs of the adjacent poor districts will be served by the new hospital.

Building operations were commenced in the year 1908, and by next year the outpatient and administration departments, six of the nine ward pavilions, operating theatre blocks, isolation block, pathological wing and medical school, and the chapel and central station, with their accessories, will be complete, and, it is believed, will constitute one of the most notable hospitals in the world. The remaining ward blocks and other extensions will be deferred until financial conditions of support justify their erection and equipment.

In the wards, 372 beds are provided for in the first portion, and are contained in six pavilions. The block on either side of the central station (now in carcass) is three storeys in height; the remaining pavilions are of two storeys. The blocks are similar in plan, each floor consisting of a main 24-bed ward, 108 ft. 1½ in. in length, with two single-bed wards and rooms for clinic, sister, duty-room, linen, etc., and a day-room for patients. In the completed scheme the whole of the south front of the hospital will be occupied by wards, enjoying the pleasant outlook over Ruskin Park.

The main corridor is 800 ft. long, and is the spine of the hospital, connecting the various buildings. The eastern part of the corridor is now in course of erection to provide direct access from the outpatient and other departments, together with the receiving room to the hospital wards.

The administration block comprises the official matron's and nursing departments, and is a building of six storeys. The nurses' home and servants' department are self-contained in the upper floors.

The present accommodation is for two hundred nurses, which in the future will be extended to three hundred. It is also hoped to provide accommodation for fifteen sick nurses on the first floor of the west wing.

Ferro-concrete on the Hennebique system has been adopted throughout for floors, stanchions, beams, staircases, and in the case of the roof to the kitchen in the basement.

The nurses' dining hall, accommodating 150, is a feature of the east block, being served directly from the kitchen in the basement below.

The board room, 42 ft. by 27 ft., is to seat forty members, and is approached by lobbies off the central corridor.

The central station is accommodated at a lower level between the two central ward blocks. Three Lancashire boilers, 30 ft. long, are provided for the supply of steam. An interesting feature of the station will be the Diesel oil engines—used, it is believed, for the first time in a hospital—for driving the electric dynamos.

The chapel and the linen department are situated at the rear of the administration block, between the two central ward blocks. The chapel is to seat 250, with wide aisles for wheeled chairs. It is arcaded and vaulted, and will have

characteristic qualities in which ferro-concrete occupies a place. The approach is by a low vaulted cloister.

The accompanying illustrations, including the Centre Plate, show the outpatients' department. The materials indicated are Lawrence's red bricks, stock bricks, and Portland-stone dressings. The turrets are covered with lead, and the arms (in lead) have been modelled by the Bromsgrove Guild.

The architect is Mr. William A. Pite; the consulting engineer Professor D. S. Capper, M.I.C.E. (of Kirkland and Capper); the sanitation is under the direction of Mr. Charles T. Walrond, A.M.I.C.E.; the contractors are Messrs. Foster and Dicksee, Ltd.; the clerk of works is Mr. Thomas Simpson, M.C.W.A.

IN PARLIAMENT.

(By our Press Gallery Representative.)

King Edward Memorial.

Captain Murray has addressed to the First Commissioner of Works further questions with regard to the King Edward Memorial. Mr. Wedgwood Benn, representing the First Commissioner, stated that the Executive Committee met on March 7th, and inspected a sketch model of the memorial which it was proposed to erect at the Piccadilly end of the Broad Walk, Green Park. The model would shortly be placed in the Tea Room of the House of Commons, with a ground plan showing the site suggested. Captain Murray asked whether the Shadwell Park scheme had had any influence in the recommendation. Mr. Benn replied in the affirmative. He added that if the Shadwell Park scheme was to be proceeded with the Broad Walk scheme must be approved.

Westminster Improvements.

Mr. John Burns has promised Mr. Fell that he will communicate with the First Commissioner of Works and the London County Council and see what can be done in the way of laying before the House a plan and description of the improvements between the Victoria Tower and Lambeth Bridge.

New Government Offices.

Mr. Wedgwood Benn has introduced a Government Bill to make provision for the acquisition of a site for public offices in Westminster, for the acquisition of land for the further extension of the Patent Office and for purposes in connection with the Record Office, to amend the Public Offices, Sites (Extension) Act, 1908, and to make provision for certain other public purposes.

Life of Timber Structures.

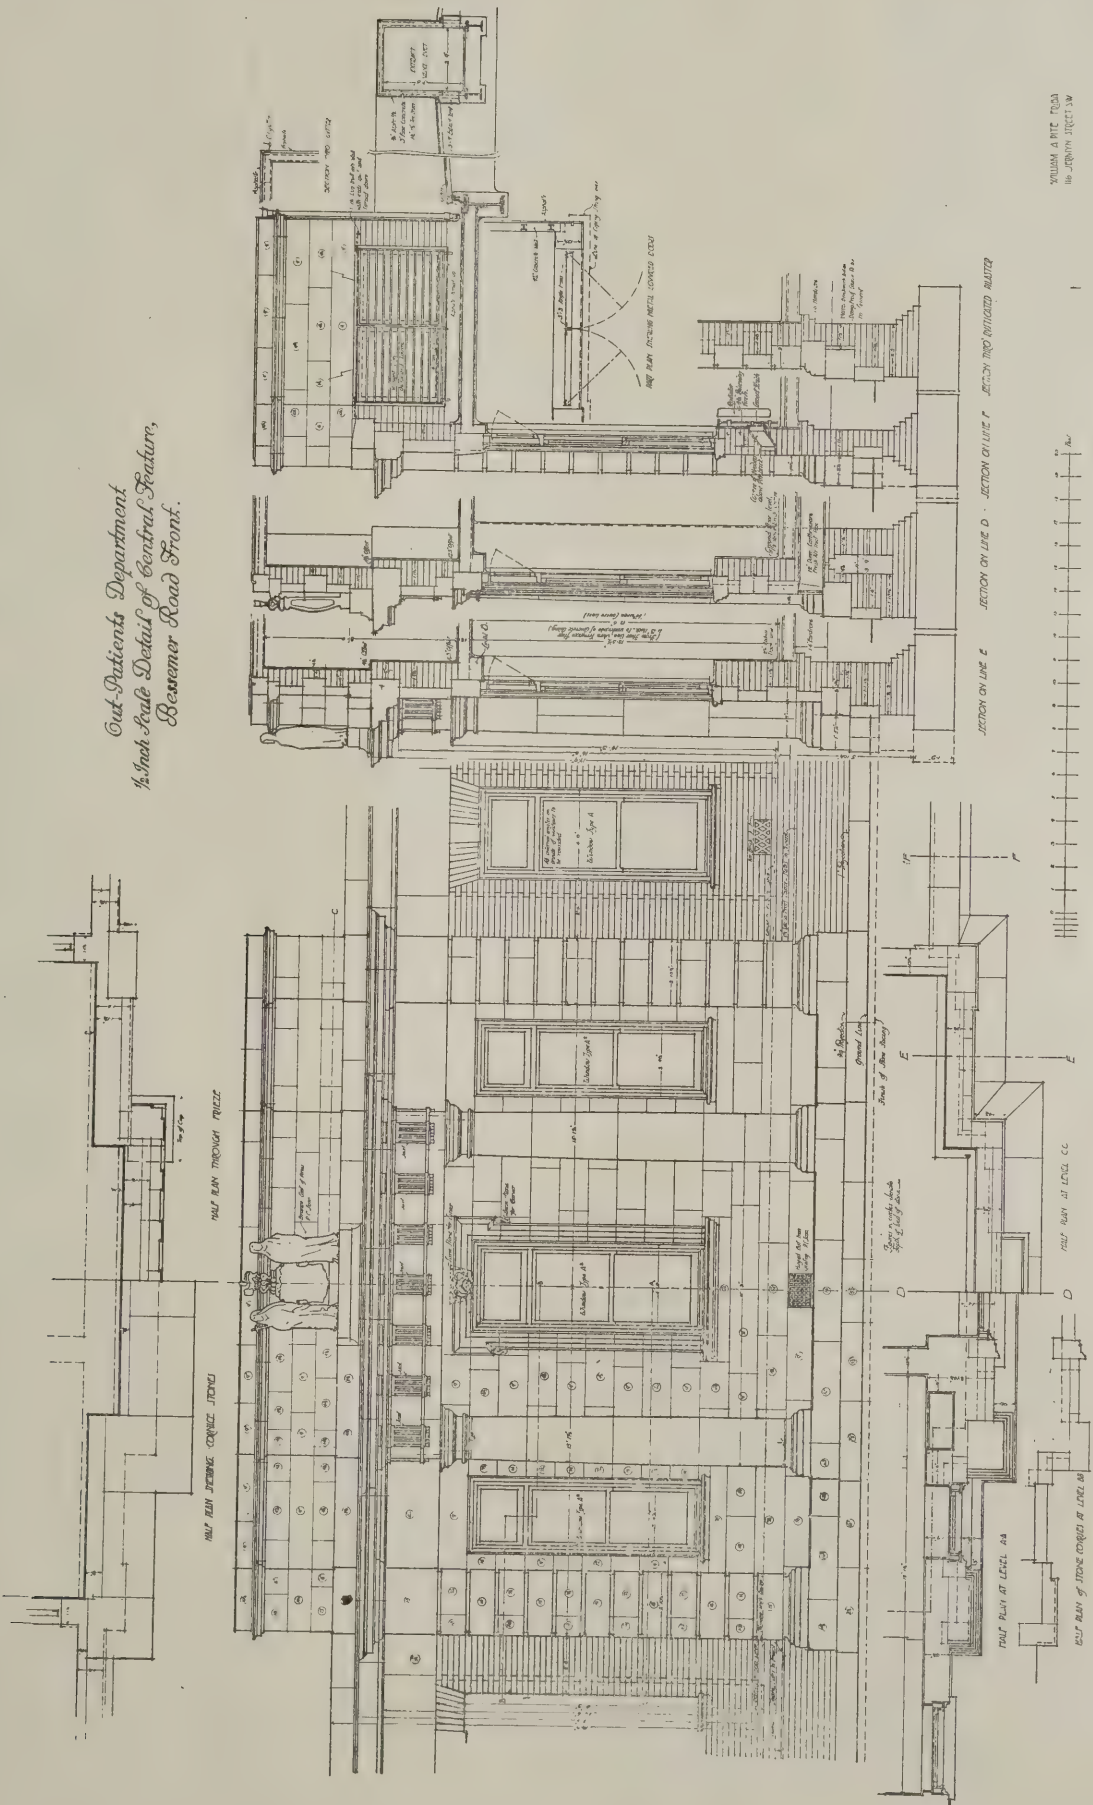

Mr. Bathurst last week made an effort to persuade the President of the Local Government Board to reduce the repayment periods for loans for timber buildings and fencing under the Small Holdings Act. He said that for fencing creosoted under pressure a term of fifteen years was allowed, and for wooden buildings chemically treated under pressure, situated upon a brick floor and with a proper roof, twenty years was allowed. In his own experience he knew of buildings made of creosoted timber which were put up thirty years ago, and were as good to-day as they were then. If wood was properly creosoted under pressure it ought to last from thirty-five to fifty years without danger of decay. The life of a building roofed with corrugated iron depended on whether the iron was properly painted with red oxide or some other preservative to ensure protection against oxidation. The life of fencing,

Architectural drawings of the University of Pennsylvania Library, including a half plan at ground level, a half plan at the first floor level, and sections A-D and C-D. The drawings show the building's facade with a large arched entrance, a series of windows, and a central tower. The half plan at ground level shows the layout of the building, including the entrance, a large hall, and a series of rooms. The half plan at the first floor level shows the layout of the upper floor, including a large hall, a series of rooms, and a central tower. The sections A-D and C-D show the building's structure, including the walls, floors, and roof. The drawings are labeled with dimensions and notes.

DETAILS OF KING'S COLLEGE HOSPITAL, DENMARK HILL, LONDON, S.E. WILLIAM A. PITE, F.R.I.B.A., ARCHITECT.

Out-Patients Department
1/4 inch scale Detail of Central Feature,
Beverly Road Front.

DETAIL OF KING'S COLLEGE HOSPITAL, DENMARK HILL, LONDON, S.E. WILLIAM A. PITE, F.R.I.B.A., ARCHITECT.

he said, must be at least thirty to thirty-five years, and if it were tarred or painted its life would be quite fifty or sixty years. He could not understand how all those structures were grouped together regardless of the actual material and the measures taken for protection and preservation. By the exigencies of debate, Mr. Bathurst was left without a reply.

Ancient Monuments.

Lord Southwark has introduced in the House of Lords a Bill for the protection of ancient monuments. It may be recalled that the Prime Minister, in the House of Commons, promised that the First Commissioner of Works would shortly introduce legislation for this purpose.

Public Works and Buildings.

The Civil Service Estimates for the year 1912-13, which have just been issued, include a sum of £3,638,080 for public works and buildings. This shows a net increase of £171,384 compared with 1911-12. For labour exchanges and insurance buildings a sum of £215,300 is asked, as against £140,000 in 1911-12. The estimate for the Houses of Parliament Buildings is £50,800. This includes £550 for providing the granite base and setting up Rodin's bronze figures "Burghers of Calais" in Victoria Tower Gardens. The expenditure of new works, etc., under this head is £2,525, as against £4,335 in 1911-12. For warming, ventilating, lighting, etc., £27,860 is required, and for furniture £3,600. For the alterations to the roof of the British Museum, with a view to better protection from fire a sum of £3,500 is to be expended during the year, the total revised estimate of the work being £9,500. Of the £25,000 required for the new Spirit Buildings at the Natural History Museum £8,000 is to be voted in 1912-13. Of £20,000 for the acquisition of property for the extension of the Royal Scottish Museum £5,000 will be required during the year. A great deal of new work is provided for in connection with post office and telegraph buildings throughout the country, and £1,000 out of the provisional total of £20,000 is to be taken for the erection of the Home Office Industrial Museum at Westminster. Of the original estimate of £95,000 for the new west wing of the Law Courts, another £35,000 will be taken during 1912-13.

The Unionist Housing Bill.

On Friday last week, Sir A. Griffith-Boscawen moved the second reading of his Housing of the Working Classes Bill, which was met by an amendment for its rejection, moved by Mr. Wedgwood. Briefly, the Bill proposes to consolidate the housing Acts already in existence and strengthen their operation. A special department of the Local Government Board is to be set up to supervise the operations of local authorities under the Housing Acts, and where local authorities neglect their duties the Local Government Board may step in and carry out the necessary reforms at the expense of the local authorities concerned. Grants from the National Exchequer amounting to £500,000 for the relief of overburdened rates for housing are contemplated. Any local authority will be empowered to pay compensation to a landlord whose slum property is destroyed on condition that he agrees not to rebuild on the same site without the sanction of the local authority. Local authorities are also given power, when a slum area is cleared, to build new dwellings in suburban and outlying districts wherever facilities for

cheap travelling enable working men to live at some distance from their work. Mr. Burns, it is to be noted, spoke strongly and humorously against the Bill, declaring that when the proposed Housing Commissioners came into the Local Government Board, he would walk out but in spite of Mr. Burns's opposition to the Bill, the amendment for the rejection of the Bill was defeated without a division, and the second reading was thereafter agreed to. The Bill, therefore, will in the ordinary course be considered by a standing committee.

NEWS ITEMS.

Newport Master Builders' Association.

Mr. W. Richard Pitt has been elected president and Mr. J. J. Partridge vice-president of the Newport and District Master Builders' Association.

The Waygood Athletic Association.

The Waygood Athletic Association held their 21st annual concert at The Horns Assembly Rooms, Kennington Park, S.E., on Monday evening, February 11th. An excellent programme was given, which was accorded a hearty welcome from a most appreciative audience.

The Design of Street Gullies.

At the Institution of Municipal Engineers, 39, Victoria Street, S.W., on Tuesday, March 26th, at 7 p.m., there will be an open discussion on "The size and design of street gullies and weirs." Members are invited to bring to the meeting drawings and, if possible, models of any street gullies or weirs which have come under their notice.

Marylebone Town Hall.

On Thursday last the Marylebone Borough Council approved the design of Mr. Edwin Cooper, F.R.I.B.A., for the new Town Hall, with the exception of the tower, which was referred back to the committee for further consideration. In accordance with the plans submitted, the estimated cost of the building is £61,913, the tower requiring £1,900. The site of the new Town Hall, is on the south side of Marylebone Road, by Gloucester Place.

The Proposed Mural Painting Exhibition.

The committee of the forthcoming Exhibition of Designs for Mural Paintings and for the Decoration of Schools, etc., have now issued a final circular containing full particulars of the competitions offered to artists and of the exhibits which it is hoped to secure. The exhibition will be opened at Crosby Hall, Chelsea, on Saturday, June 1st; and a number of definite offers of wall-spaces to be decorated and of funds to bear the expenses have already been secured. The circulars will be sent to anyone interested on application to the Hon. Secretaries, Mural Decoration Committee, Crosby Hall, S.W.

Auctioneers and Estate Agents' Institutes Amalgamate.

The amalgamation of the Incorporated Estate Agents' Institute with the Auctioneers' Institute of the United Kingdom (Incorporated) was formally agreed to at an extraordinary meeting of the Estate Agents' Institute at Hanover Square recently. Mr. Howard Frank, the president, was in the chair, and there was a large attendance of members, including Mr. James Boyton, M.P., who is a

past-president of both organisations. It was resolved to wind up the Estate Agents' Institute voluntarily, Mr. W. H. Wells and Mr. W. J. Taylor being appointed to carry out the formalities.

Business Memoranda.

Claridge's Patent Asphalte Co., Ltd., 21, Surrey Street, Strand, W.C., announce that they have now been connected to the telephone service, number 8836 City. A notice of this firm's products was given at p. 223 of issue for February 28th.

Lock Woven Mesh reinforcement (Messrs. George F. West and Co., Caxton House, Westminster) is being used in connection with the Windsor Castle water supply, for covering the new reservoirs, by H.M. Office of Works.

Messrs. John Tanner and Son have been entrusted with the whole of the reinforced concrete floors, with fibrous plasterwork and decoration in conjunction, at Longton Town Hall, Staffs., the architect of which is Mr. T. J. Beckett, of Longton.

Changes of Address.

Mr. H. Guicharde Todd, F.S.A. (Scott.) M.S.A., architect and surveyor, has moved from 6, Cheapside, E.C., to Southampton House, 317, High Holborn W.C. Telephone: Holborn 627.

The Atmospheric Steam Heating Co. (1907), Ltd., announce their removal to more central premises, 22, Broadway Westminster, S.W. The new telephone number is 5833 Victoria; telegrams to "Metro, London," as usual.

As from March 15th the offices and warehouse of the Yale and Towne Co. (from which only a wholesale business is conducted with the trade) are removed to 17-20, West Smithfield, London, E.C. Telephones, 7660 City; 7661 City. Telegrams, "Yaletowne, London." At the new premises, considerable additional accommodation has been provided for the firm's constantly increasing business to facilitate the handling and despatch of all orders, and a comprehensive stock of Yale products (patent locks, etc.) will be held to meet all demands.

The Prudential Assurance Company.

In presenting the sixty-third annual report of the Prudential Assurance Company, on March 7th, the chairman stated that the total income of the company was £15,252,937, being an increase of £370,961. The company, he said, provided for all classes, accepting premium yearly, half-yearly, quarterly, monthly or weekly. Applications from industrial policyholders who desired to discontinue payment of premiums and accept for policies were 4,570 less than those received during 1910. £500,000 had been applied to writing down ledger values, securities and increasing the investment reserve fund. The total surplus was £3,469,908, and there was an increase in bonus in both branches. Industrial branch—5 per cent. to 50 per cent. on claim during the forthcoming year (in 1911 £6,760,000 has up till now been distributed by way of bonus and increased benefits amongst industrial policyholders). Ordinary branch bonus—36s. per cent. There had been a decreased rate of expense in both branches—Industrial branch, 33 per cent. on income; Ordinary branch, 6 per cent. on income. Increase in interest yield was recorded; and there was every probability of increased bonus rates in the future. The company, it was announced, are forming an approved society for the purpose of working the National Health Insurance Act.

oured to forget it as quickly as possible. But this does not obtain. He will advertise his misdeeds without compunction side by side with other works of his own of which he may reasonably be proud.

Another element which militates against much real progress is the growth of specialists. Not only do the ordinary structural specialists flourish on every hand, but they will go beyond their European prototype by contracting to carry out an architect's small-scale design, with detail and ornament of high technical and perhaps artistic merit, without the architect in the multitude of the other concerns of his profession having to trouble himself too much on this head.

Execution.

The American architect appears to have wider responsibilities than the architect here. This is more particularly true in the case of the larger works. There is a very general understanding that each man should rule his own roast. The architect will be expected to produce a satisfactory result without having to be guided except on general lines by the client. It may be that the client is only building as an investment, and knows nothing of good or bad work.

In such circumstances the architect will probably find himself with an absolutely free hand.

This will demand from him close attention to rule and convention. Any hostile criticism of eccentricity of design will shake the faith of a purely commercial speculator, and so we find a certain amount of restraint upon originality and genius.

Building Regulations.

Another restraining element is the fact that in most of the large centres there is a very rigid building regulation which demands the production of full plans, details, and calculations for inspection by the local authority in order that a building permit may be considered. The omission of essential information will delay the permit being issued, and the work itself will be consequently retarded. Novelties or variations from customary procedure will, as may be expected, be looked upon with suspicion by the building officials, and cause possibly lengthy explanations and inquiry.

When his building permit is obtained there is the risk of objection by the building inspector if variations from the approved plans are attempted.

In this position the architect will also feel compelled to work upon safe lines. He cannot have the luxury of watching his building develop and of making alterations and improvements in the design as the work proceeds.

Of course, the splendid generosity of wealthy patrons frequently affords the architect an opportunity of exhibiting his genius free from all such trammels as have been referred to above.

I venture to suggest, however, that these isolated cases do not represent the main stream of architectural life in the country.

Further Restrictions.

Remember, too, that native artisans are practically non-existent. The architect may even find it necessary to have his work executed here in England or on the Continent. This cannot conduce to progress.

The crude native sculpture on some Celtic monument is still more highly regarded than the careful carving by the contemporaneous workmen in the streets of Rome of ornament and design copied from the Greeks.

Do not let us forget that we are here discussing American architecture, and I make the distinction between a native effort towards an ideal which shall be characteristic of the land and its marvellous people, and an architecture which may largely consist of careful adaptation of European models, but which shows no real ground for hope of progress in the near future.

Education.

Whatever I have said which seems to criticise adversely modern methods must be discounted in considering future prospects. Architecture will be safe from degeneration if continued effort is made on proper lines to train the coming generations. Not only will it tend to develop the art of architecture, but it offers a restraining influence upon the eager but unqualified who press into the profession.

A high standard of education is becoming more and more essential. The tremendous interests, both public and private, which are at stake in many of the large undertakings demand a high degree of technical skill. I think that public sympathy is strong on the side of rigorous examination and qualification for all practising architects. This, of course, is a hopeful sign, and the universities are alive to the necessities of the case. Harvard, for instance, offered a five years' course. There was an entrance examination which included English, French, German, Physics, Drawing, and Histories of Greece and Rome. The student had the advantages of a hall of casts, painting-room, exhibition-room, modelling-room, library, photograph dark-rooms, etc. The first year's course included the Technical and Historical Development of Ancient Styles, Drawing in Line and Colour, Mathematics, Languages, and Physics. In the second year Design, Perspective, Statics, Resistance of Materials, Mediæval Renaissance, and Modern Styles were added. In the third year Building Construction, Theory of Design, Masonry and Foundations, and Mineralogy were taken. In the fourth year, in addition to general topics, two special subjects had to be taken from a list which included Design in Painting, Sculpture, and Architecture, Greek Art, Fine Arts of the Middle Ages and of the Renaissance, Classical Archaeology, Private Life of the Romans, Life in Ancient Greece, Landscape Design, Æsthetics, Bridges and Buildings, Health and Ventilation. The average gross cost to the student for residence and education was only £100 per annum.

There was a somewhat similar programme given in connection with Washington University, and at a somewhat similar cost.

The Massachusetts Institute of Technology at Boston gave a very full five years' course with a continuous training in design for three years' Freehand Drawing throughout and one complete year in the Life Class. A feature of these college courses is the Summer Schools. I have a note of one which was in the form of a tour to Europe particularly for the study of the work in the northern towns of Italy, finishing with a bicycle excursion from Genoa to Paris.

The University of Pennsylvania offered three separate courses—namely, a four-year course leading to the degree of Bachelor of Science in Architecture, another course leading to the degree of Master of Science in Architecture, and a shorter two-year course. There was an

additional three years' course in Interior Decoration.

The Syracuse University provides almost equal facilities for the student. These are but illustrations of the numerous facilities for study and preparation for the profession.

The total result is generally seen in the fact that the majority of the young men in the offices of practising architects are college men with a college degree. Incidentally, there is a minimum of the mechanical drudgery which in many London offices is handed over to inexperienced youths who may possibly grow up to exploit the special features of the work done by their employers.

If one may venture into the realm of prophecy, it must be to express the belief that there is a bright prospect for architecture in America.

Education of Public Taste.

The question as to whether this will be realised in the near or distant future depends upon one main factor—namely, the education of the public taste for the beautiful. As matters stand at the present time, art may be degraded and good taste may be corrupted by being compelled to follow on the heels of those who act on the principle that just as in some commercial undertaking wealth and power can demand a rigid obedience, so in the realm of art the artist must follow the lead of his employer, provided he can purchase his compliance at a princely price.

The good time would be brought within measurable distance by a period of commercial depression. Architects might then find time to turn their attention to the everyday affairs of the community. A tenement house would not then be recognised as now, as a ghastly imitation of a factory, or the ordinary suburban dwelling as something very much akin to a wooden barn.

Architects might even find time to raise protests against the desecration of the public streets by hideous advertisements and encroachments upon the public convenience by corporations whose only concern is for the dividends of their shareholders. There would then grow up a corporate sense of what is good and that a man should not have a free hand to offend the good taste of his fellow citizens, even though he may be a successful business advertiser.

"In Truth and Beauty."

In conclusion, may I again venture prophecy that if we are anxious to make real progress we shall do so only on the lines adopted with success in the States. Registration is a futile procedure if it results only in shutting within a rind fence the good and the bad. We must begin where all real progress begins—in the school and in the workshop, in the public press, in the common affairs of life. When the authorities who are responsible for the bridges across our rivers and the lamp-posts in our streets, when the factory and the mine proprietors who can and does blast the landscape and ruin our buildings by the reek of their works, when the workman, as in days gone by, recognises that it is as easy to make a beautiful thing as it is to make an ugly thing, when the community at large expects that the little things of life shall be presented in a true and beautiful form, we shall have no cause then for anxiety for those larger works which have too long been looked upon as the only and proper sphere for the architect and artist alike.

PENNSYLVANIA STATION, NEW YORK: FAÇADE TO SEVENTH AVENUE. McKIM, MEAD AND WHITE, ARCHITECTS.

II.—MR. C. C. BREWER.

The chief characteristics of American architecture to-day seem to me to be vigour, competence, singleness of purpose. All these are, of course, the outcome of the national spirit, the amazing commercial activity, and the climatic conditions. A country progressing at the speed of America to-day has crying need of a race of competent and vigorous architects, and forces them to the single purpose of erecting the best possible building in the shortest possible time. It leaves them no leisure for the "Hopes and Fears for Architecture," or "Philosophic Doubts." Do not let me be misunderstood. I am not suggesting that haste is apparent in the best building of America of to-day, for I hold strongly that the architects are rising, with almost incredible success, to meet not only the commercial and practical needs of the community, but to work out artistic problems with a certainty, a dignity, and a breadth the equal of which it would be hard to find in any other period. Indeed, I believe the history of architecture of

mean than in most European countries, for the Americans are dealing with big schemes and new ideas even in advertising, and mean buildings grow less mean when set in the ample suburbs of American cities.

Pennsylvania Railway Station.

As an example of what I mean by big ideas, even in advertising, I would instance the new Pennsylvania Railway Station in New York. A new station becoming necessary, the idea that the finest and largest station in the world might be no bad advertisement seems to have occurred to the directors, and their next step was to employ an architect of large and fine ideas; their choice fell luckily upon Mr. McKim. He seems not only to have entered into their scheme, but surely his enthusiasm must have carried them on till the undertaking grew almost in the spirit of cathedral builders. The result is a temple to the glory, not only of the Pennsylvania Railway Company in particular, but of well-ordered and swift transport. You have probably all seen photographs of

office buildings, and banks. Can the Americans be learning the market value of repose in the midst of their strenuous life?

It may be argued that there is no real newness in this great Pennsylvania Station—that the hall is a mere translation of the Baths of Caracalla on, I believe, a larger scale; that the detail on this and most other buildings of the same type in America is directly taken from Italy or Greece.

Evolution of National Style.

This brings me to the wider criticism of their architects which is so often made by Americans to-day: that they are not evolving a national style. It is surely difficult for contemporaries to judge whether or not a style is being evolved in any art, and it is probable that the same critics, had they lived in the seventeenth century, in Italy, would have been chiding the architects for being mere copyists of the Romans.

I cannot believe that men who are approaching architectural problems with the freshness, vigour, and clearness of

UNION STATION, WASHINGTON. D. H. BURNHAM AND CO., ARCHITECTS.

the last twenty years in America will be read almost as a fairy story by future generations.

Rush and Hustle.

Mr. Daubney has hinted at the conditions of rush and hustle under which these buildings are produced, and has not—could not—exaggerate it; nor should it ever be forgotten in judging the results. It is, indeed, a matter for amazement and admiration that even skyscrapers, for which the working drawings of a completeness undreamt of in England are said to have been made in a period which could barely suffice with us for the preliminary sketches, do not more often shriek aloud to the world the horrid tale of the speed of their conception, labour, and birth.

In judging the works of architecture in any country to-day I hold, of course, that it is only fair to put out of court perhaps 75 per cent. of the buildings. We must judge by the large public buildings, the railway-stations, the office blocks and stores, and by the thoughtful and more serious domestic work for either the rich or poor.

An international comparison of cinematograph palaces, public houses, and the domestic vulgarities of the newly rich on the one hand, or the meannesses of the jerry-builder on the other, would be neither to the point nor profitable; the first are merely a form of pictorial advertising, and the jerry buildings are merely temporary structures within the meaning of the Act. In America, however, I believe that there is a smaller percentage of both the blatant and the

this wonderful building; but no photographs can give an impression of the effect which its vastness, orderliness, and completeness produce on coming to it out of the turmoil of New York.

Imagine an entire railway station with fittings and furniture, even to the spittoons, designed by the architects; a railway station so planned and so contrived that there is no noise nor bustle, where no porters intrude with luggage, and where it has even been thought worth while to forgo the profits of the bill-sticker that all may be well ordered and dignified. This last was the culminating stroke of genius, for the effect of a station where even the notices are subdued and where the direction signs are of bronze set upon marble tablets and advertisements are not, upon the mind accustomed to walls, ticket offices, and lamps covered with lettering and pictures of every size and shape is one of almost bewildering calm. It is as if the directors had said: "We will startle the public, not with glare and noise of our money-making, but with dignity and repose." And so to-day the conception of a railway station as a dignified thing seems to have taken hold of the Americans, and we have the big Washington Station and others in the same spirit. Comparing these with the three latest termini in London—the Great Central and the two at Victoria, which had not even the sense to be one—we weep for London.

The Dignity of Enterprise.

This idea of the dignity of commercial enterprise seems growing upon the business men and showing itself in the stores,

thought of the Americans of to-day will not leave behind them something worthy to be called a national style, even if they are content, for the while, to use and reuse the language of the past.

Speed and hustle are the natural parents of copying in architecture. The man, set face to face with enormous problems to be tackled at great speed, turns naturally to the text-book for his details, and I am not sure that, given speed as one of the conditions, the results do not gain in the process, for the architect has the more time for mass and the big idea.

The Trend of Architectural Training.

Certain it is that the trend of architectural training in America is to this end—to train competent architects and competent assistants, not thinkers and writers on architecture. The man who knows where to find chapter and verse in those wonderful libraries which seem to be a *sine qua non* in every large office, and how to use the matter when found with a competent good taste and discretion, is the man to help the designer of big schemes. And I must admit that one rarely sees a draughtsman on the architectural side of a big office without a great folio of Renaissance or Classic art at his elbow.

A word as to training. Mr. Daubney has given a rough sketch of the curriculum in vogue some ten years ago, but has said no word as to the influences at work within the schools themselves. That this is entirely French no one will deny. At the time of my visit Harvard was preparing to celebrate the arrival of a French-born, French-speaking, and French-trained Pro-

fessor of Design, and Harvard was the last college to hold out against the Beaux-Arts tradition. All the others had already either Frenchmen or Americans trained in the French manner as their guiding spirits. Harvard and Boston architects had long fought for training on more English lines, but the force of the Beaux-Arts movement, as evidenced by the roll of students in their own and other colleges, counselled surrender.

French and Italian Influence.

In the face of this it is a matter of surprise to me that American work is not showing even stronger evidences of the French fashion. This may be somewhat accounted for by the great influence of McKim, who, although French-trained, yet drew most of his inspiration for his later work from Italy. But I hope the reason is rather the growing strength of a tradition of their own, a strength fostered by the individuality of the American character, and their brilliant qualities of self-reliance and rapid, straightforward thought.

As to the influence of their own colonial style, this seems to me for the moment under a cloud. Much that has been perpetrated by the jerry-builder under cover of the word colonial has swung the pendulum of fashion a little far from New Zealand and Virginia, and, although many men of taste and

culture are using the vernacular in their domestic work, one is a little sorry to find that development along these lines does not seem likely.

The Growing Feeling for Gothic.

The lack of mediæval building in America itself, and latterly the Beaux-Arts training, no doubt account for the poverty as a whole of the ecclesiastic and domestic work. The wave of the Gothic revival can only have been a feeble ripple by the time it reached the States, for it left behind it a trail of thin and wiry buildings of unimaginable meanness.

Richardson, with his strong if at times somewhat clumsy hand, left his mark upon the town halls and churches of his day, and was followed by less strong men, who, by their eccentricities, soon brought his manner into disrepute. His influence seems to linger, to-day only in the West, where the work of that brilliant architect and contriver of clever detail Mr. Louis Sullivan still shows signs of early Richardsonian influence. The success of Cram and Goodhue's Gothic scheme in the competition for the rebuilding of West Point, and the masterly manner in which they are carrying it through in the face of much adverse criticism, is evidence that there is now a finer feeling for Gothic work. The French and Classic tide is not quite sweeping all

before it, and there still remains a small but faithful band of thoughtful men—"the Englishmen," they sometimes call themselves—who are fighting against it. The little leaven of their work may not be without good effect upon the lump, especially in the one quality in which American work of to-day seems lacking.

Shams.

On my return to England our work, at all events in our towns, had a very depressing effect on me. It seemed mean and muddled, and with an uncertainty and a hesitancy about it, as if we had been for many years without a goal. But we seemed, especially in the country, to have one quality which American work had not; I mean the right and truthful use of material. In the States one's sense of decency and honesty is constantly being hurt, and one's nerves jarred by shams so cleverly carried out as to deceive the eye if not the hands. I could quote instances without number, but one must suffice. There is at West Point a charming memorial hall by McKim; the interior has many bronze ornaments—some are cold to the touch, others, more difficult to reach, are warm. The entrance to the large hall is through a screen of caryatid figures, ostensibly of bronze; but the discovery of a horrid wound of plaster where two toes have been kicked off seems to take away any value the

PENNSYLVANIA STATION, NEW YORK: MAIN WAITING HALL, WITH EXIT TO THIRTY-THIRD-STREET.
McKIM, MEAD AND WHITE, ARCHITECTS.

building may have as a memorial. The use of stucco for stone, of plaster painted, and most cleverly painted, as oak, would seem not to be confined to the music-hall and the saloon, or to the work of vulgar men: such things are surely unworthy of so great and rich a nation. In England, even in our poverty to-day, we have one great heirloom from our Gothic past, a certain love of honesty in materials, which gives even the weakest of us a sense of shame in their wrong use.

If I might borrow a little American confidence to sum up what seems to me the strongest characteristic of their race, I would say, "Knowing what they want and getting it." When the architects realise that besides vigour and certainty, competence and dignity, delicacy and brilliancy, they want also honesty, they will get that too, and then American architecture will come to its own.

DISCUSSION.

Mr. H. M. Fletcher, proposing a vote of thanks, remarked upon the extraordinary singleness of purpose of the Americans. Town planning was to them a very real thing, and schemes were being produced in amazing numbers. In no other country had so many great plans been produced within the last few years. They included schemes for Chicago, Cleveland, and Washington, which last city it was proposed to convert into a whole series of vistas. New York, of course, was not a fine example of city planning, and never could be, because of its restricted situation on an island. The Americans in their architecture, he continued, were giving all their attention to mass, grouping, and the big features; detail either went all to pieces, or was taken bodily from other buildings. An undoubted advantage was that the rich men of the country were anxious to have big schemes carried out.

Mr. A. G. R. Mackenzie, seconding the vote of thanks, and recalling a few impressions of his visit to the United States five years ago, said he met Stanford White, and saw some of his older work. Of the distinguished partnership to which he had belonged, White was rather the archaeologist. He periodically visited Europe and brought back with him quantities of material, including ceilings, tapestries, and even whole rooms. He did a great deal in the education of public taste in America; and it was owing to public interest in architecture that the progress there was so great. In America they talked about architecture as our public here talked about sport and the theatre.

Mr. W. H. Ward regretted the lack of originality and the absence of a national style in American work, but perhaps it was too early to expect anything of that kind. For future progress he was confident in the present methods of education; and he thought that, working through a European style, in the course of a half-century or so a national style would be evolved. They had made many experiments in various styles; but their Gothic, as represented by the New York Cathedral and the Roman Catholic Church on Broadway, did not impress him very favourably. One would find there, also, examples of every branch of Renaissance work in every country. It was in America three years ago, and when the Colonial style was the latest thing in domestic work. Apparently this had now been abandoned in favour of something else, thus illustrating the uncertainty of architectural opinion.

Mr. T. M. Whitelaw commented upon our inferior methods of education.

Mr. Arthur T. Bolton said he had not been to America, but had met a number of American architects. When at Seville, the speaker said he had drawn the attention of an American architect to the tower there, but he only replied, "I have an office in Madison Square, and I look out on that tower every day." [Mr. Brewer had previously shown, side by side on the screen, illustrations of the tower at Seville and its American reproduction by White.] Referring to the comparison, Mr. Bolton said that White had not been particularly successful in copying the original. In the case of this particular architect to whom he had referred, the rush of life in New York had completely knocked him out and destroyed his nervous system. Americans travelled very largely, of course, usually with an eye to business, and thus gained an interest in architecture which, with a large amount of money at their disposal, they were able to gratify to some purpose. It was said that too much attention generally was paid to old work; but if a new people in a new country did this there must surely be some reason for it.

Mr. Gerald Horsley said he was rather surprised that, in an account of American architecture, more was not said about Richardson and Hunt. Those two men were really the founders of modern American work, and they were both Englishmen. For some years past an American friend had kindly sent him the "Architectural Record," a publication which gave one a full insight into the progress of modern architecture in America.

Mr. Daubney, in reply, said that in America an architect was able completely to exhaust himself on his work. There was not so much of cramp as in England, and fewer limitations. There was not the necessity to grapple with difficulties in order to get round a problem. He could not help wondering whether the architecture of America would not be greatly advanced by a commercial catastrophe; for then the architect would be compelled to do more thinking.

Mr. Brewer, in reply, said the Americans were not mere hustlers; they were as keen as, if not keener than, we are in the appreciation of fine architecture. Over there the public were quite familiar with architects' names, and would discuss architects and what they were doing just as the same class of people here would discuss pictures. Referring to a question by Mr. Horsley, the speaker said the reason why little attention had been given to Richardson and Hunt was because of the large number of buildings existing which were mere caricatures of the work of the two men. Almost every town in America had a clumsy copy of some work by Richardson, and his style was one which did not lend itself to copying. They would not, perhaps, find delightful detail in American work, but there was nearly always an absence of muddle. The best shops and business places no longer employed big unsightly lettering for names on the fascia board; indeed, it was largely the practice to use a small neat letter on a metal plate, as had been done in the case of the Selfridge Store.

During the course of Mr. Brewer's lecture a large number of recent American buildings were shown upon the screen, many of which had been illustrated in our *Edition de Luxe*, 1909. With regard to the Municipal Office Building, New York, designed by McKim, Mead, and White, and illustrated on page 288 of this issue, Mr. Brewer supplied a few interest-

ing particulars. For this building, he said, more than 260 working drawings had been prepared by eight men in six months. These drawings, which were worked out to the minutest detail, were subsequently photographed down to a small scale, lithographed, bound up into volumes, and distributed for use. Two tramways and two tube railways run immediately beneath the building.

LAYING OUT THE NEW CAPITAL OF INDIA.

The Secretary of State for India has, at the request of the Government of India, appointed a committee of experts to advise the Government of India as to the site of the new capital at Delhi, and the laying out of the same. The committee will consist of Captain George Swinton, Chairman of the London County Council; Mr. John A. Brodie, C.E., City Engineer to the Corporation of Liverpool; and Mr. Edwin L. Lutyens, F.R.I.B.A. Mr. H. V. Lanchester, F.R.I.B.A., who is at present engaged in work in India, will join the committee. The committee will assemble at Delhi about the middle of April, where it will find materials ready for consideration, and will have the assistance of the Department of Indian Public Works, and of other Departments of the Indian Government. It will act under the instructions of and report to the Government of India. Its work, which will be of a general and preliminary nature, and will involve no questions of detailed planning or architectural design, is expected to occupy four or five months.

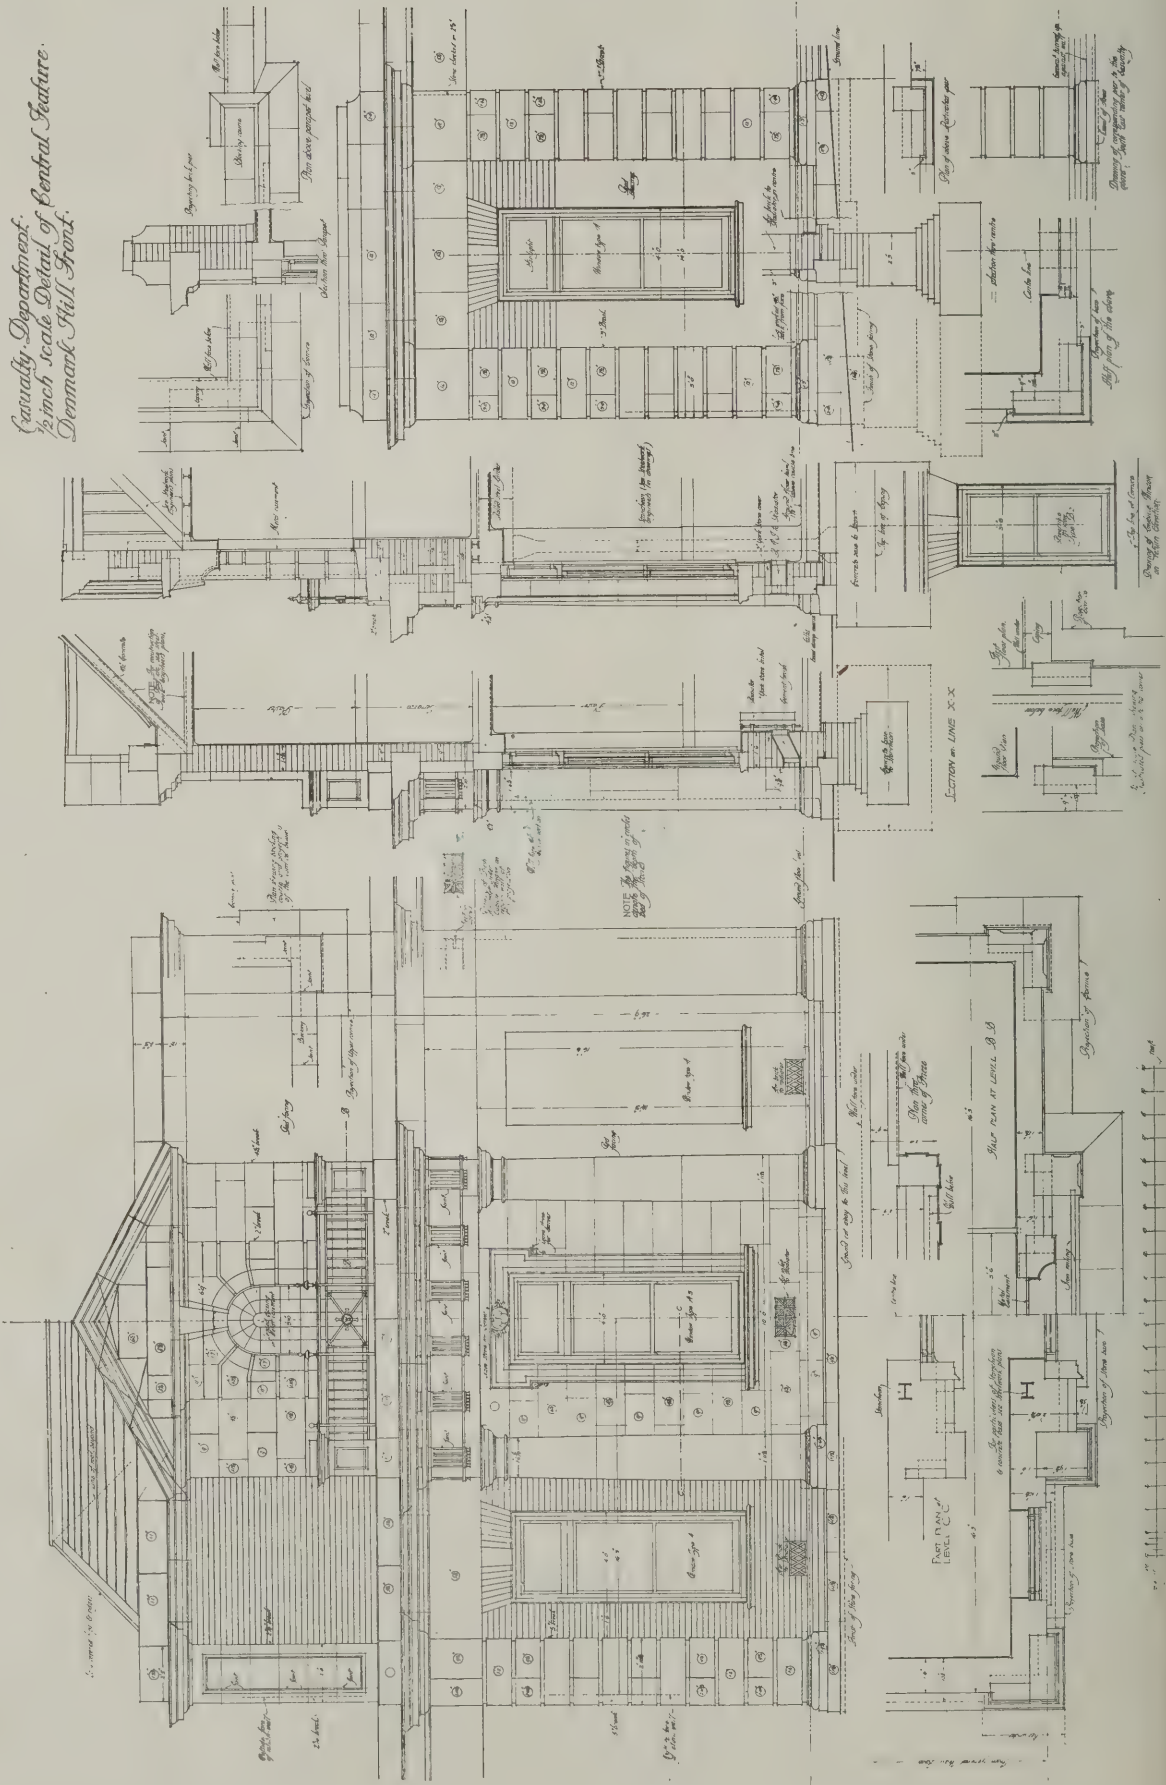

For the temporary accommodation of the Government of India during the five years the building of the new capital is expected to occupy, an area has been selected along the Alipur Road, between the present civil station of Delhi and the Ridge, where there are to be temporary offices and residences. The architecture and method of construction will be similar to those adopted in the exhibition buildings at Allahabad in 1910; but the buildings are expected to outlast the transitional period for which they are intended. They will subsequently be an asset of some value, the site they occupy becoming a suburb of the capital.

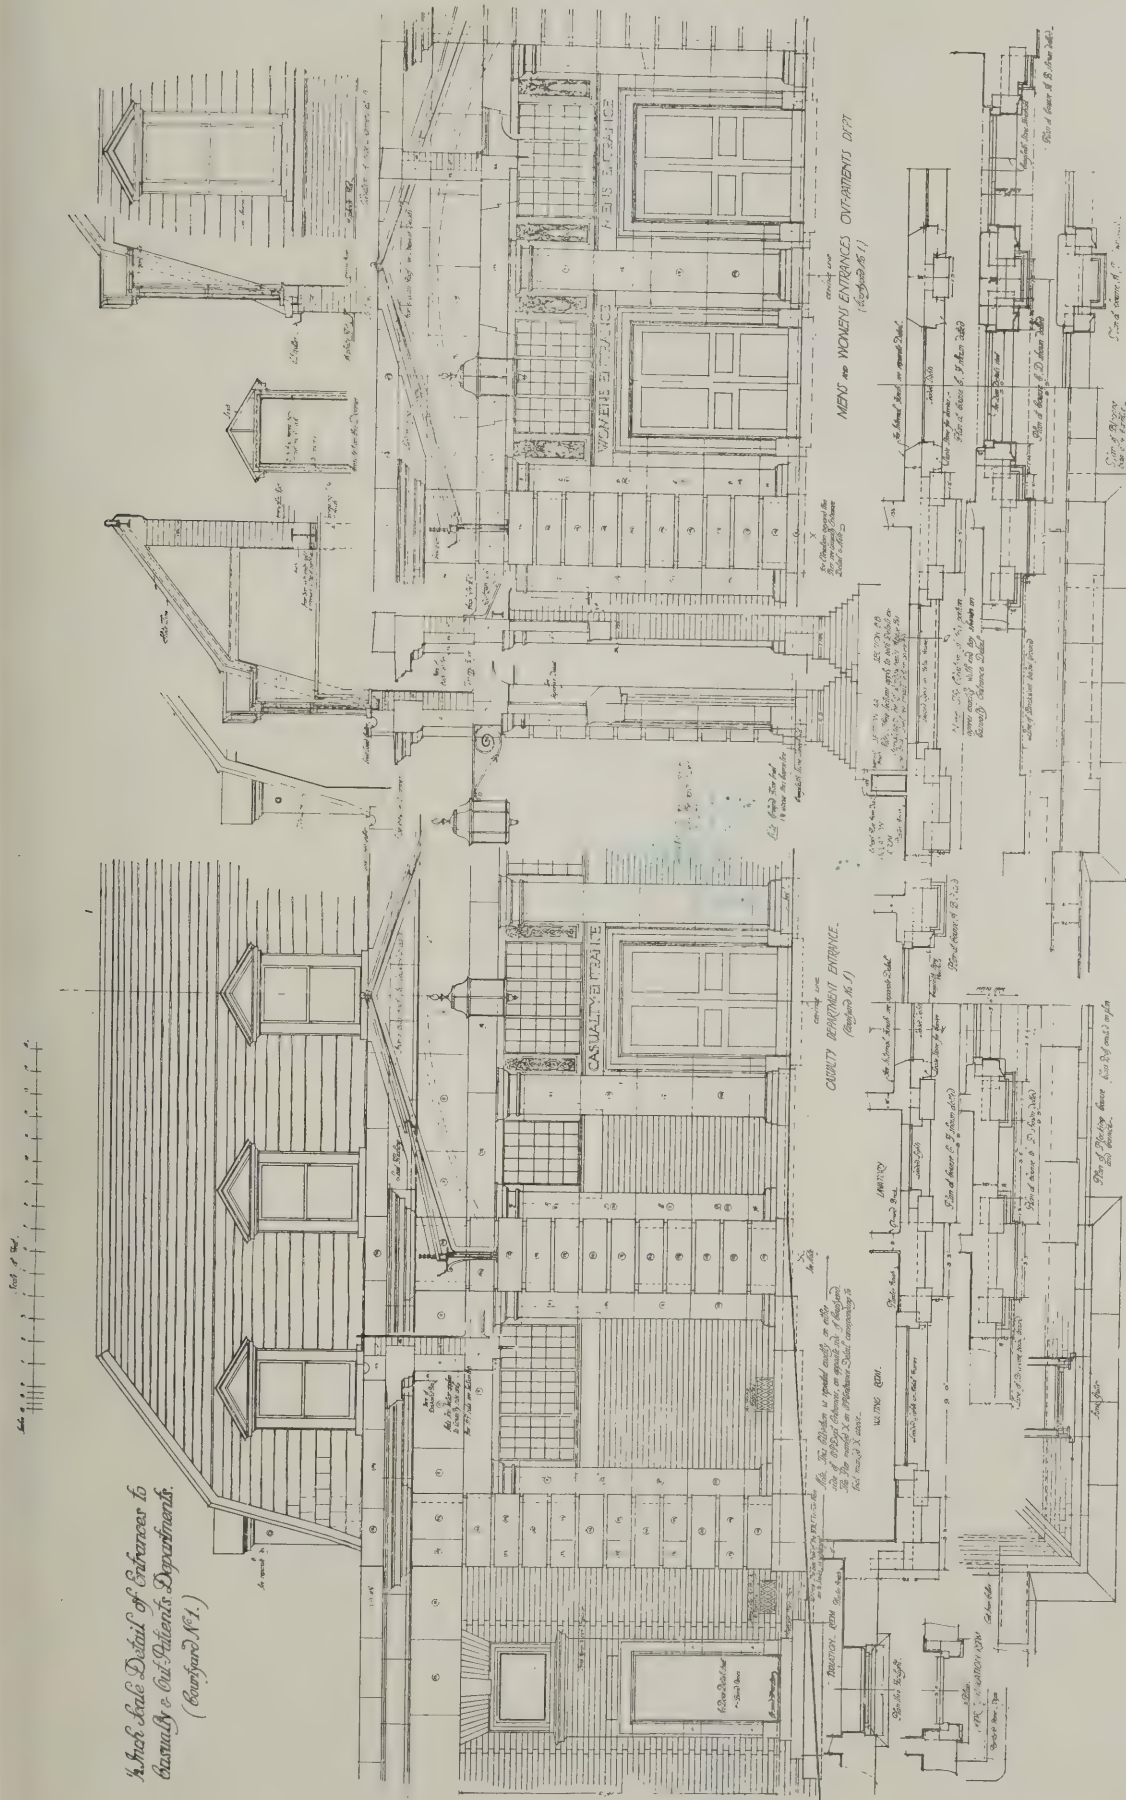

The offices to be built along the Alipur Road will form three sides of a square, and will be flanked on either side by lines of offices for the secretariat clerks, etc., and a temporary Council Chamber will adjoin the line of offices. Temporary houses for the registrars and European clerks may be erected near the Ridge, probably in the vicinity of the Khaibar Pass.

The late Mr. John Kershaw.

Mr. John Kershaw, whose death recently occurred in London, was for some years connected with the Great Indian Peninsular Railway, and also with the firm of Sharp, Stewart, late of Manchester, and with the Oldbury Carriage Works, near Birmingham. For the success of his superintendence of the G.I.P. railway at the famous Bore Ghaut, he received the thanks of the Indian Government. Mr. Kershaw was a member of the Institution of Mechanical Engineers and of the Royal Society of Arts. His only brother, Mr. S. W. Kershaw, F.S.A., who survives him, was for some years connected with the Royal Institute of British Architects.

DETAILS OF KING'S COLLEGE HOSPITAL, DENMARK HILL, S.E. WILLIAM A. PITE, F.R.I.B.A., ARCHITECT.

ELEVEN-INCH CAVITY WALLS.

BY EDWIN GUNN, A.R.I.B.A.

↑ Cavity walls, consisting of two $4\frac{1}{2}$ -in. thicknesses, with a 2-in. cavity, are now being largely adopted in cheap building, owing to the sanction of this form of construction given by the latest Local Government Board model by-laws. While they are greatly superior to 9-in. walls, and sometimes even to 14-in. solid walls, in dryness and non-conduction of temperature differences, their structure requires more thought and care, if they are to be sound, than it sometimes receives, and there are certain qualities (both good and bad) which they possess that do not appear to have been hitherto dwelt upon. Dealing with these latter qualities first, they are:—

(1) Great rapidity of heat radiation when rooms are warmed and the cavity is freely ventilated from outside. In thicker cavity walls, where the inner wall is 9 in. thick or over, this is not noticeable; but the $4\frac{1}{2}$ -in. skin quickly becomes warmed from within in cold weather, and creates a decided up-current of air in the cavity, drawing in fresh cool air from below, and continually losing heat in this way. The method of ventilation described later goes some way to remedy this.

(2) Quick drying of walls owing to ready admission of air to mortar. This makes it possible to get buildings ready for healthy occupation in considerably shorter time than usual.

(3) Liability to attack by frost when building, owing to similar reason.

(4) Economy in facing bricks owing to absence of headers ; also possibility of use of brick five courses to the foot with ordinary four-course backing without disturbance of bond.

Footings.

The 11-in. wall contains no more bricks than a 9-in. wall, and places no greater load on the foundations. It is therefore reasonable to give its base no greater spread—that is, 18 in., allowing one course of footings to be absorbed by the cavity. As the inner wall carries the bulk of the weight, the full spread should be preserved on this side, but, in order to save cutting, the courses between top of footings and bottom of cavity may be built out as shown by dotted lines (Fig. 1). Where the floor joists require a bearing block, footings may be formed on the inner face (Fig. 2).

Damp Course.

The cavity is often stopped on the damp-course, and alternatively is sometimes taken down as far as the footings; both practices are faulty. It must be remembered that the *theory* of the hollow wall is that dampness may penetrate the outer skin, but must stop there, and the *fact* is that some amount of moisture does so penetrate. Its natural course is downwards, and should the damp-course continue through both thicknesses moisture is there arrested in its downward course, and spreads to the inner wall or even to the ground-floor plate, which is usually bedded direct on the dampcourse. If, on the contrary, the cavity continues below the ground line, it may become charged with water percolating through from the soil. The best place to stop it is below the dampcourse, and at least one course above the ground, an angular cement fillet being formed and a few vertical joints left open for the escape of moisture (Figs. 1 and 2). A continuous bitumen dampcourse is best, as

slates $4\frac{1}{2}$ in. wide are too small to be economically suitable.

Openings.

Door and window openings must be built solid at the jambs, but the point of contact should be reduced as much as possible, which may be done by clipping bricks as shown (Fig. 3). Frames penetrating the cavity should be avoided when practicable, a workable treatment at jamb, sill, and head being shown. The frame is grooved on back, and grouted in with cement from above when the brickwork has been built up. The horns of sill and head are left on (cut back as shown), and by these expedients the frame is firmly fixed. At the sill a course of flat tiles bedded in cement closes in the cavity, and the head is covered by a concrete lintel cast in position, a tilted board or fillet being temporarily fixed to keep the lead strip over the window head in place and preserve the cavity while casting (Fig. 4).

Floors.

The inner wall carries most of the weight, and should not be weakened by building in wood plates to support floor joists, as the whole of the wall above must rest on them, and when shrinkage occurs will settle and probably loosen the ties. A stout hoop-iron bearing bar should be run continuously through the wall to receive joist ends (Fig. 5), every third or fourth joist being spiked to a breeze brick built in to receive it, to give the requisite tie. A still better plan would be to use an American "wall anchor" (Fig. 6), but I have not succeeded in getting these in this country.

Eaves.

At the eaves the two skins should be united by building solid for a few courses, which may be done here without bad results, as the outer surface is protected by the roof projection. This ensures the roof load being partially borne by the outer thickness. A simple oversailing

enables the work to be bonded without much cutting or waste. (Fig. 7).

Ventilation of Cavity.

It is now generally admitted that fresh air circulation through the cavity is desirable, but certain disadvantages frequently entailed by direct ventilation have been mentioned. If, however, the inlets to the cavity are formed from within, below the floor space, and the outlets at the top, just beneath the solid over-sailing, two purposes are thereby served. The upcast current produced in the cavity creates a pull on the air below the floors, and greatly assists the usually sluggish ventilation here, by drawing in air from outside through the air bricks communicating with the floor space; and the indirect and consequently slower circulation so set up considerably retards the degree of heat-loss from the rooms. The shafts conducting air from outside to the floor space should be sealed off from the cavity with slates and cement (Fig. 8); and if these are formed (as they usually are) under window openings and the inlets to cavities intermediately, in the piers or plain wall faces, the desired object is achieved.

MAGAZINES AND REVIEWS.

"The Art Journal" contains a copiously illustrated article by Mr. Jourdain on "The Works of Robert Adam: Kedleston"; nothing, however, is said about the house itself and its remarkable plan, only about the furniture it contains, which, it appears, has been carefully preserved. It is, however, a very motley collection, much of it saying little, or perhaps a great deal too much, about the taste of the designer and his time. Some of the things—such as the gilt four-post bed, with its realistic palm-trees at the angles, and the carved wooden *torchere*, with the stem formed of three twisted snakes, whose heads make a tripod at the foot—are atrocious; others, especially the fire-grate which figures at the head of the article, are admirable, both in taste and design, and seem to belong to a different world. The chamber-organ case also is very good. The impression one gets is that Adam had no central ruling principle in his furniture design; he designed in two styles, one of them as good as the other is bad, and his name cannot in the least be accepted as a guarantee of good taste in furniture design. Mrs. Stuart Erskine contributes an article on "Some Flaxman Relics," containing some interesting information as to the sculptor's life, and illustrations of some of his works not generally known, among them the model for a seated statue of Telford, with a bas-relief of the Menai Bridge on the pedestal. It appears that Wedgwood, for whom Flaxman did so much beautiful work, was not at the outset in the least conscious that he had secured the co-operation of a man of genius, and spoke with indifference about the engagement of the artist; but he seems to have appreciated him in the end. A curious incident is the story of his offer to Flaxman of a book written by an Italian and dedicated "All'ombra di Flaxman," under the impression that the sculptor was already dead. Flaxman accepted both the book and the apology, and died five days after. "Chimney-pieces of the Early Georgian Period," by Mr. Francis Lenygon, is the opportunity for the publication of some fine examples.

The "Burlington Magazine" commences with an article on "The Decorator as Artist," the intent of which apparently

Detail of Principal Entrance.

NEW COUNCIL HOUSE, KIEL.
D. HERMANN BILLING, ARCHITECT.

is to recommend the work of Mr. Robert Vigors, whose special aim is to modernise some of the typical styles of interior decoration—Elizabethan, Louis Seize, Adam, etc.—retaining their general spirit but treating them in a way to harmonise better with modern life and habits. This is a more reasonable treatment than mere imitation; and the illustrations of interiors which he has treated look well. "Rajput Paintings," with some illustrations, is part of the craze which is just commencing for the semi-barbaric pictures of early Chinese and Indian artists. This will probably go on for some time now, and we shall be asked to believe that these works are far superior to the benighted Western Art of the nineteenth and present centuries. Without countenancing any such exaggeration, one may find the examples given of much interest in an archaeological sense, and we also agree with the recommendation made in another article, by Mr. Lionel Cust, that it would be well if all the treasures of Oriental art in London were collected into one museum, where they could be studied together, instead of being distributed over the British Museum and two departments of the Victoria and Albert Museum. But the value of Oriental art consists in decorative work and applied art, not in naive attempts at picture-painting.

In the "Nineteenth Century" Miss Gertrude Kingston revives a very old demand, in the words "Wanted: a Ministry of Fine Arts." The suggestion has been made in print over and over again. Miss Kingston gives one crucial instance of what happens in the present state of things. She wanted to buy "some pillars and fine old chimneys and fan-lights" that were being carted away from the houses in Great George Street, demolished by order of the Government. But on applying at the Office of Works (which she incorrectly calls the "Board of Works") she was told she must apply to the house-breaking contractor, as they were his perquisites. As she says, truly: Can one imagine such a thing occurring under a properly equipped Ministry of Fine Arts? Of course, we know that such a piece of negligence is a trifle compared with the far greater and more serious mistakes that are made in connection with London architecture, for want of there being a competent and constituted authority to look after them; but the incident is a very characteristic one, and was worth relating.

In "Scribner," under "The Field of Art," Mr. Bashford Dean writes an article on "The Armourer and his Art," which calls attention to the important position held in the mediæval and early Renaissance period by the armourers; and he draws attention to the fact that it was not only the business of the armourer to decorate the armour richly, but that he was to produce beauty in it without in any degree losing strength.

The "Moderne Bauformen," published at Stuttgart, occupies its February number entirely with illustrations of the new Council House at Kiel, of which Herr Billing, of Karlsruhe, is the architect. There is a great deal of merit in this building, though the architect seems to have made a too defiant attempt to be original by refusing all the usual refinements of an architecture based on Classic—putting square stone piers, with only a mere hint of a capital, in place of Classic forms. This avoids imitation no doubt, but produces a rather bald and uninviting architecture. We give two illustrations of the general view and the main entrance.

The "Architectural Record" includes a good article by Mr. M. Stapley on "The most excellent master Baldassare Peruzzi," an architect of the Italian Renaissance who hardly got the opportunities or the fame which his genius merited, though his name is permanently connected with two beautiful Roman palaces, the Massimi and the Farnesina, of which the latter used to be credited to Raphael, but the consensus of architectural historians is now in favour of Peruzzi's claim to it. Perhaps, however, the Albergati palace at Bologna may not unfairly be classed as superior to either; it is more robust and logical architecture than the Farnesina, the very flat pilaster Order on which is, after all, rather a conventional source of effect, while the Albergati depends entirely on the fine treatment of windows disposed symmetrically in a large surface of wall. An article by Mr. Cheney on "The American Academy in Rome" is of some interest as indicating the present feeling of the Americans in regard to the value of Roman study. The general conclusion seems to be that there are two centres of education for American architects—Paris for technique, Rome for culture—and that the intellectual culture of the architect has been hitherto rather neglected in America. In that case the new Academy at Rome may be a means of supplying this deficiency.

JOTTINGS FROM PARIS.

The Palace of Agriculture.

The proposed new Palace of Agriculture will probably not be built on the site of the Halle aux Vins, in virtue of the energetic protest of a mass meeting of about six thousand persons interested in the wine industry, who naturally hold that the demolition of their hall will be "deplorable from all points of view."

Organisation of Apprenticeship.

The subject of apprenticeship has been very earnestly discussed at a meeting of the Congress of Commercial and Industrial Groups. The view generally expressed was to the effect that the problem of apprenticeship should be taken in hand by chambers of commerce and other commercial and industrial associations, with State subventions, and that local and professional conditions should be respected.

African Army Monument.

The competition for designs for a monument to celebrate "the glory of the armies of Africa," to be erected at Algiers, has been decided in favour of M. Monestel, architect, and M. Maurice Favre, sculptor, who will work in collaboration. The jury consisted of MM. Cauvy, director of the Ecole des Beaux-Arts; Fourquet, professor at the same school; Rochegrosse, the painter; and Mulot, the sculptor.

M. Daumet's Successor.

The successor to M. Daumet at the Académie des Beaux-Arts is M. Edmond-Jean-Baptiste Paulin, who, born in Paris on September 10th, 1848, won the Grand Prix de Rome in 1875. He is, of course, a professor at the Ecole des Beaux-Arts, and an Officer of the Legion of Honour. He was awarded a *grand prix* at the universal exhibitions of 1889 and 1900, and for the former he designed the Chateau d'Eau and the palace of chemistry and mechanics.

International Housing Congress.

An international housing congress is to be held in Amsterdam in September, 1913. The programme, which has been recently adopted at a meeting of the permanent committee at Brussels, deals with town-planning, the housing of the working classes, and the sanitation of congested areas, etc., etc. On the proposition of the French delegates, the congress will collect information concerning the results obtained in various countries from experiments in municipal housing.

Mosaics at Montmartre.

Thanks to the bequest of 500,000 francs by an anonymous donor, an extensive scheme of mosaic decoration is to be applied to the chancel of the Church of the Sacred Heart at Montmartre. The work has been entrusted to M. Luc-Olivier Merson, who hopes to see its completion within about five years, which is perhaps rather an optimistic estimate in consideration of the fact that the surfaces that are to be covered represent 465 superficial metres.

Government Architects' Fees.

The French general Budget for 1912 provides that as from January 1st, 1913, the remuneration for architects engaged on works executed at the expense of the State shall not exceed five per cent. of

the cost of the contract. In cases in which the work is situated at a distance of more than twenty kilometres from the ordinary place of residence of the architect, expenses incurred in travelling and living away from home will be allowed. There are special scales for (1) works of maintenance and repair; (2) works of artistic character; and (3) works situated abroad.

Housing Betterment.

The housing question has become acute in Paris, and is receiving a good deal of attention. Accommodation for people of the clerk and artisan class is scarce, dear, and insalubrious, and the demand for cheap and healthy houses is becoming clamorous, and special legislation, empowering the city of Paris to build working-class dwellings is being demanded. It is at length realised that whilst in Belgium, England, Germany, and Italy, sanitary amelioration has made enormous strides, in France there has been absolute stagnation. The evils of overcrowding, and the insanitary character of old houses in which it takes place, are becoming painfully evident in the hospitals; and it is added that many of the proprietors of the slum dwellings are themselves poor, and lack the means of setting their houses in order, even where the will is good. Consequently the cost of reform is likely to fall upon the municipality or the State; and M. Brunet, municipal councillor, has demanded a loan of two hundred million francs (or not very far short of a million pounds sterling) for the construction of cheap dwellings, the designs for which, he proposes, shall be thrown open to competition. In the meantime, many industrious and ingenious persons are busying themselves with the old familiar calculations as to relative cost, rental, and accommodation; and already the fear is expressed that the necessity for cheapness may result in ugly buildings of monotonous uniformity of type when once the cheapest form of dwelling has been at length ascertained. A project that is being considered by the Chamber of Deputies provides for "the creation, in Paris and in communities of more than 100,000 inhabitants, of cheap dwellings." The interest on such schemes, as regards Paris, is to be limited to 2½ per cent., and that for provincial schemes is not to exceed 3 per cent.

Legislation and Labour Unrest.

Paris, like London, has its labour troubles. There, as here, in the spring the workman's fancy lightly turns to thoughts of strikes; and the masons, taking advantage of the busy period that is just coming into full swing, are demanding a nine-hours day and a revision of wages. The employers, for their part, are grumbling very heartily about the proposal that has been introduced into Parliament to limit the working day in certain industries to ten hours. In particular they point out that if in the building industry nobody is to be allowed to work for more than ten hours, that will, in some instances, necessarily imply a further reduction of two hours a day for certain classes of workmen, especially those employed in yards and workshops, whose output would otherwise be greater than could be dealt with in the reduced hours by those to whom the work passes on in due sequence. In the Chamber of Deputies, M. Vaillant has brought forward an amendment demanding an eight-hours day. It was defeated.

CORRESPONDENCE.

Ironwork in Holy Trinity Church, Sloane Square.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—I notice in your issue for March 6th a photograph of the chancel gates in Holy Trinity Church, Chelsea, with a note stating that the metalwork was executed by Mr. H. Wilson. This is incorrect. All the ironwork for the chancel, the pulpit stairs, and the electric light fittings were designed by Mr. Sedding and carried out by my firm, Longden and Co., under Mr. Sedding's directions. Mr. Wilson designed some ironwork later, in other parts of the church.

H. LONGDEN.

3, Berners Street, Oxford Street, W.

[The number of craftsmen who were engaged in carrying out Sedding's scheme has made it difficult to dissociate the work of one from the other; hence our error, which we are glad to correct. The ironwork which Mr. Longden says was designed by Mr. Wilson "later" is presumably the outside railing, already illustrated in our columns. Mr. Wilson was also responsible, we believe, for the fine metalwork that screens the organ pipes.—Eds. A. and B. J.]

"A Century of Building": St Matthew's, Northampton.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—In your report of a paper on "A Century of Building" (in your issue of March 6th), read by Mr. Maurice B. Adams, occurs a rather curious mistake which leads up to, somewhat interesting coincidences. Amongst the works accredited to J. L. Pearson is the church of St. Matthew, Northampton, but this was designed and carried out entirely by the late M. H. Holding, A.R.I.B.A., who, strangely enough, was a pupil and an assistant in Pearson's office, so that in this case the usual course of events is reversed, the master here getting credit for the work of his pupil, although the former was, I believe, deceased years before the work was started.

Another slight and excusable error is, in reference to Godwin's works, Canon's Ashby, which is the home of the Drydens, and most interesting from an artistic and architectural point of view, is given as belonging to the Marquis of Northampton. It should have read "Castle Ashby," where Godwin designed the entrance lodges. The Town Hall, Northampton, is also mentioned as his work, and this again brings up the late M. H. Holding's name; for, when the extension of this building was undertaken, the design submitted for the front by him was selected and carried out, and the combination of the work of the two men is most successful. There are other houses in this town designed by Godwin, and, taking Rhinefelden and one at Dallingington built for Mr. Shuttleworth, in composition and in the proper use of materials they are fine examples—the latter especially, the sketch for which I believe I am right in saying, was evolved on a sheet of notepaper and in a railway train on one of his visits.

I am sending this correction as to St Matthew's as an old pupil of, and in fairness to the reputation of, the late Mr. Holding. I can vouch for the accuracy of my statement, as I had the pleasure of helping on the actual drawings. HERBERT NORMAN, Licentiate R.I.B.A.

PICTURE EXHIBITIONS.

The Dowdeswell Gallery.

For the exhibition of "gardens and other watercolours" by Miss Beatrice Parsons, at the Dowdeswell Gallery in Bond Street, criticism is out of place; there is no room for any feeling but enthusiasm. This is either the second or third exhibition of Miss Parsons's work at this gallery, and her treatment of garden scenery, whether in regard to foreground detail or general pictorial effect, is simply perfect; we do not think anything could go beyond it; and it is hardly necessary to name any particular examples when all are so beautiful. The only difference between this and former exhibitions is that the artist has now for the first time, as far as we can recollect, made figures an important feature in some of her scenes. The Virgin and Child in the "Agnus Dei" picture forms a beautiful group; if the figures in the "Merrie England" picture are not quite so perfect as the garden scenery, they show every promise in this line of painting, a promise confirmed by two or three charming separate portraits of children. But as to the garden scenes there is no question that Miss Parsons is the first painter of the day in this class of subject. In the scenes in which portions of Winchester Cathedral come in the architecture is also very well treated.

The Leicester Gallery.

The modern tendency towards sketchiness in both landscape and figure painting receives more illustration than it generally does at the Leicester Gallery, in the two collections of work by Mr. F. Bramley and Mr. Peppercorn respectively. Mr. Bramley is, of course, an artist of no ordinary powers. Although the collection as a whole rather suggests sketches in oil, some of them are very effective as far as they go; "The Road," for instance, as a landscape, and the study of "Nelly" with her head nearly turned away from the spectator, seen against a background of foliage; there are other interesting landscape studies. In the exhibition of Mr. Peppercorn's works, "Evening near St. Just" is the best, and there is a fine sentiment in it.

The Goupil Gallery.

The owners of the Goupil Gallery have had the happy thought of making up a memorial exhibition of works by the late James Aumonier, one of the finest English landscape painters of our time, who certainly ought to have been elected a member of the Royal Academy, an honour which has been conferred on landscape-painters who, though more popular, are by no means his equals. It appears from the prefatory notice in the catalogue that his name, about the middle of his career, was down as a candidate for election at the Academy, but the honour was so long delayed that in 1902 he, with a very natural feeling of self-respect, withdrew his name from the list of candidates. The Academy have been unfortunate more than once in their neglect of landscape-painters who merited higher consideration, and it is not creditable to their judgment that Aumonier should have been left outside. The exhibition at the Goupil Gallery contains a great number of his smaller watercolour studies of landscape, and some, though perhaps not quite the best, of his larger and more important oil-paintings; the one which represents his art at its best, among those in the exhibition, is "Farm at Shepreth," a landscape exceedingly French in style;

PNEUMATIC SPRAYER FOR INSECT-DESTROYING SOLUTION BY R. SUMNER AND CO., LTD.

but there are other very fine oil paintings on a smaller scale. Aumonier, it appears, commenced his career as a designer for calico printing, his first attempts in painting being studies of foreground flowers; yet he never lapsed into being a foreground painter in landscape; on the contrary, his mature works are remarkable for their breadth of style and fine sense of landscape composition. He was a member of the Institute of Oil Painters, and was one of the small group of landscape painters, originally six in number, who used to give an annual exhibition of their works. He obtained a gold medal at the Paris Exhibition of 1889.

TRADE AND CRAFT.

Exterminating Insect Pests.

Builders very often, and architects occasionally, are required to deal with insect pests which, while they sometimes infest houses to such an extent as to render them positively uninhabitable, are always more or less of a disgusting nuisance, to which hitherto it has not been easy to oppose an effective remedy. To meet this difficulty, Messrs. R. Sumner and Co., Ltd., manufacturing chemists, 50A, Lord Street, Liverpool, have introduced a solution that instantly kills insects, and, what is equally important, they have devised an effective means of applying it. If bugs, fleas, cockroaches, etc., were not inaccessible in their lairs, their extermination would present no difficulty; but they cannot be got at by ordinary means, and so, behind woodwork, and in other concealed nooks and crannies, they increase and multiply in defiance of all ordinary efforts to dislodge them. Messrs. Sumner have devised a sprayer of pneumatic action, and having a special nozzle, with a star-shaped flow, from which liquid radiates for a distance of 5 ft. in all directions. The liquid, known as solution D, is said to consist of certain synthetic derivatives of coal-tar in combination with volatile and mineral oils. It is proved to be absolutely fatal to all forms of insect life; it destroys not only the insects, but their eggs. Wherever an insect can go the spray from this pneumatic instrument can follow; and on board ship, where the nuisance from

insect pests is often intolerable, it has been found entirely efficacious to bore a $\frac{3}{4}$ in. hole in the woodwork of an infested bulkhead and, by inserting the nozzle of the sprayer, reach every part of the interior with the insecticide, and thus free the otherwise inaccessible interior from every trace of vermin. The fluid is strongly disinfectant, and by means of a small tap its discharge can be regulated from a light spray to a strong stream. It should be of special value in hotels, hospitals, and similar institution. The fluid, it is stated, is harmless to woodwork or upholstery.

The Installation of 'Phones.

The Western Electric Company, Ltd., North Woolwich, London, E., have issued, as their "booklet 107," a set of most useful "Instructions for Installing Westophones, Interphones, and Single-line Telephones," illustrated with ten clearly and carefully drawn diagrams, showing complete details of all arrangements for connecting-up, etc. These are accompanied by directions which are set out in the simplest possible language, every operation, with the reasons for it, being fully and lucidly explained, as well as the working of the instruments after the installation has been completed. The booklet will be found invaluable to architects who wish to inform themselves upon every point in the installations which they specify, as well as by the specialists entrusted with the actual work.

A Hertfordshire Bacon-Curing Factory.

The preliminary arrangements in connection with the formation of a bacon-curing establishment at Hitchin have been completed, and the plans and specifications for the new undertaking, which have been prepared by Mr. Loudon M. Douglas, F.R.S.E., of 3, Lauder Road, Edinburgh, who is technical adviser to the society, are now ready, and will be issued forthwith to the various contractors who are desirous of tendering for the work of construction. The undertaking, which owes its initiation so largely to Lord Lucas, will be known as the Herts and Beds Bacon Factory. In ordinary circumstances the factory should be completed in about six months' time.

SOCIETIES AND INSTITUTIONS.

ARCHITECTURAL ASSOCIATION,

House List.

The following are the Council's nominations for the House List for the Session 1912-1913.—President, Gerald C. Horsley; vice-presidents, W. Curtis Green, Maurice E. Webb; hon. secretary, H. A. Hall; hon. librarian, W. H. Ward; hon. editor, A.A. Journal, P. Cart de Lafontaine; hon. treasurer, Arthur Keen; council, A. T. Bolton, C. C. Brewer, H. P. Burke-Downing, F. C. Eden, G. L. Elkington, Stanley Hamp, A. G. Horsnell, Geoffrey Lucas, Winton Newman, T. Fyfe, W. G. Newton, A. G. R. Mackenzie, W. J. Tapper, A. Gilbert Scott, J. Alan Slater.

DEVON AND EXETER ARCHITECTURAL SOCIETY.

Annual Meeting at Exeter.

The annual meeting of this society, which embraces the counties of Devon and Cornwall, was held at the Half Moon Hotel Exeter the President, Mr. James Jerman, F.R.I.B.A., of Exeter, in the chair.

The annual report was presented by the hon. secretary, Mr. Allan J. Pinn, and the balance sheet by the hon. treasurer, Mr. S. Dobell. The retiring president, Mr. James Jerman, having been thanked for his address and also for the able manner in which he had discharged the duties of his office during the past year, the meeting then proceeded to elect the officers for the ensuing year, as follows: Mr. E. Coath-Adams, M.S.A. (Plymouth), President; Mr. J. A. Lucas, A.R.I.B.A. (Exeter), Vice-President; Messrs. J. M. Pinn, L. F. Tonar, T. A. Andrews (Exeter), R. H. Arthur (Plymouth) to fill vacancies on the Council of those retiring, as well as those remaining in offices—viz., Mr. H. L. Thornely, F.R.I.B.A., Mr. Sampson Hill (Redruth), and the two past presidents, Messrs. W. H. May, M.S.A. (Plymouth), and James Jerman, F.R.I.B.A. (Exeter), Mr. S. Dobell, hon. treasurer, and Mr. Allan J. Pinn, A.R.I.B.A., hon. secretary.

Subsequently the members lunched together, and during the day the visiting members were conducted round the city, among the places visited being the Rougemont Grounds, the Law Library, the Bishop's Palace, the Cathedral, College Hall, Guildhall, and several churches and mediæval buildings.

In the annual report it was stated that after the removal of six names, one by death and five by resignation, the roll of members now stands at eighty-four. It is recorded that when the new by-laws for the city of Exeter were adopted, the City Council gracefully acknowledged the services rendered by members of the Society in their revision. The president and several members of the society were present at the ninth International Congress of Architects, which was held at Rome last autumn.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

Scottish Renaissance Architecture.

A general meeting of this society was held on March 7th at the Leeds Institute, the President (Mr. Sydney D. Kitson, M.A., F.R.I.B.A.) in the chair. A lecture on "Scottish Renaissance Architecture" was given by Mr. Laurence Weaver, F.S.A., Hon. A.R.I.B.A. A series of slides showing plans of houses and castles, illustrated the fact that the towers formed their keynote—unlike the English plan, which developed from the hall. It was pointed out that the Scottish Renaissance

was entirely based on French influence, owing to the political connection between the two countries; whereas in England the influence of Italy and the Netherlands was general. The Scottish Renaissance was much later than the English, and the tenacity of the Old Baronial style is remarkable.

NORTHAMPTON ASSOCIATION OF ARCHITECTS.

This association was formed in March, 1911, and has now become allied to the Royal Institute. The first annual general meeting has recently been held, when the treasurer was able to present a satisfactory balance sheet. After a vote of thanks for past services, the president, Mr. J. A. Gotch, F.R.I.B.A., the vice-president, Mr. Sidney F. Harris, F.R.I.B.A., and the council and hon. secretary were re-elected. During the past session monthly meetings have been held, when papers have been read and afterwards fully discussed. It is proposed to organise a few summer excursions, and to re-assemble for the monthly meetings in the autumn.—HERBERT NORMAN, Hon. Secretary.

YORK AND YORKSHIRE ARCHITECTURAL SOCIETY.

A paper on "Sketching" was read before the above Society last week, by Mr. William Whitehead, A.R.I.B.A., of Leeds. Mr. Whitehead, in dealing with the subject, divided it into the following sections: The uses of sketching, the mediums and styles, composition, and what to sketch. There were times, he said, in everybody's life when they desired to put some of these impressions and ideas into more material form. Something more than mechanical draughtsmanship was necessary to delineate the very numerous and varied detail of modern times for the guidance of craftsman and workman. To attain this degree of proficiency in the various mediums, nothing was more helpful than sketching. Other advantages to be claimed for sketching were familiarity with proportion, detail, and construction and perspective.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.

"Architects of the Stuart Period" was the title of a lecture delivered to the members of the Birmingham Architectural Association last week by Mr. Mervyn E. Macartney, F.R.I.B.A., F.S.A., architect to the Dean and Chapter of St. Paul's Cathedral, and to Durham Cathedral.

International Smoke Abatement Exhibition.

An exhibition will be opened on Saturday, March 23rd, at the Agricultural Hall, Islington, N., under the auspices of the Coal Smoke Abatement Society. The exhibition will comprise all the latest appliances for the use of smokeless fuels both in the home and in the factory, and there will be a large and attractive display of gas appliances for cooking; for hot water supply; for the heating of houses, shops, factories, churches, and other public buildings; and for furnace work. Every afternoon and evening demonstrations of cooking by gas will be given, with practical hints in the economising of gas, and in the most effective utilisation of cookers, grillers, hot-plates, etc. Tickets of admission will be supplied by the Gas Light and Coke Company to any of their consumers who will apply at any of their offices.

COMPETITIONS.

LIST OF COMPETITIONS OPEN.

MARCH 25TH. SCHOOL, COLCHESTER.—The Borough of Colchester Education Committee invite architects practising within the borough to send in Competitive Plans for a School for about 750 children to be erected on a site in Hamilton Road, Colchester. Plans must be delivered by 12 o'clock noon on March 25th. Apply to Ernest H. Bultitude, Clerk, Education Offices, 8, East Stockwell Street, Colchester.

MARCH 31ST. NEW PARLIAMENT BUILDINGS, WINNIPEG.—The date formerly announced for the close of this competition has been extended to March 31st.

APRIL 20TH. BIRMINGHAM BLUE COAT SCHOOL.—Competition strictly limited to Birmingham architects. In a preliminary competition, three designs will be selected, and the authors will be paid £50 each to develop and redraw their plans to a larger scale, showing further details. In the event of the Governors failing to proceed with the second competition, the authors of the three designs will be paid £25 each. Assessors, Mr. G. H. Hunt, F.R.I.B.A., of London, and Mr. Charles E. Bateman, F.R.I.B.A., hon. consulting archt. to the Governors. Drawings to be delivered by mid-day of April 20th to Mr. William E. Bolton, Secretary, The Blue Coat School, Birmingham.

MAY 1ST. PUBLIC BATHS, WOMBWELL, YORKS.—Wombwell U.D.C. invite designs for swimming-baths to be erected in Hough Lane. Premiums, £40, £30, and £20. Stamped and addressed foolscap envelope to W. Quest, surveyor to the Council, Town Hall, Wombwell.

MAY 15TH. COUNCIL OFFICES, PORTLAND.—Portland U.D.C. offer premiums of £50 and £10 respectively for first and second designs. Particulars (deposit 10s. 6d., returnable) from R. A. Colenutt, Clerk to the Council, Offices, New Road, Portland. [The date has been extended from that formerly announced.]

JUNE 28TH. TOWN PLANNING. HALE.—Premiums of £50 and £25 are offered for a town-planning scheme.—Address Council Offices, Hale, Cheshire.

JUNE 1ST. INSTITUTE, NETHERTON DUNFERMLINE.—Cost not to exceed £7000. Premiums, £20, £15, and £10. Assessor Mr. E. A. Jamieson. Apply, Secretary Carnegie Trust, Abbot Street, Dunfermline.

JUNE 30TH. MUNICIPAL BUILDINGS PADIHAM.—Designs for town hall, baths etc., are invited. Premiums of £40 and £20 are offered. Address, J. Gregson A.M.Inst.C.E., Surveyor's Office, Padiham.

AUGUST 30TH. THE HENRY SAXON SNELL ESSAY.—The Henry Saxon Snell prize of fifty guineas and silver medal of the Royal Sanitary Institute is offered for an essay on "Suggestions for Improvements in the Ventilating, Lighting, Heating, and Water Supply Appliances and Fittings for an Operating Room and its accessory rooms for a General Hospital of 400 Beds (no Students)." Essays (in which two competitors of different professions or crafts may join) to be delivered before 4 p.m., August 30th, to the Secretary Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., from whom full particulars may be obtained.

THE ARCHITECTS' & BUILDERS' JOURNAL

WEDNESDAY,
MARCH 27th, 1912.

Volume XXXV.

No. 897

DETAIL OF AN OLD HOUSE IN BROAD STREET,
HYTHE, KENT.

[Photo: News Illustrations Co.]

MODEL OF THE KING EDWARD MEMORIAL, TO BE ERECTED IN THE GREEN PARK, LONDON.

BERTRAM MACKENNAL, A.R.A., SCULPTOR. E. L. LUTYENS, F.R.I.B.A., ARCHITECT.

THE ARCHITECTS' & BUILDERS' JOURNAL.

MARCH 27th, 1912.

CAXTON HOUSE, WESTMINSTER.

VOLUME 35. No. 897.

NOTE : *The List of Contents will be found on page IV. of the front advertisements.*

The King Edward VII. Memorial.

HE site for the memorial to King Edward VII. was definitely fixed at the meeting of the Memorial Fund Committee held on March 21st. The site bordering on Piccadilly, with the memorial facing southward towards the Queen Victoria Memorial, was agreed upon with only four dissentients, and the architect and sculptor are to be commissioned to carry out the work according to the design shown in the model, of which we give an illustration on the opposite page. The result, however, was not arrived at without a good deal of adverse criticism, some of which was not without point.

One of the objections was that the whole monument, while placed near to Piccadilly, would turn its back to that main thoroughfare. The objection, as put by Sir Squire Bancroft, that the statue of the King was turned with its back to Piccadilly, was a little over-stated, as the monument will not have that effect; the architectural erection which forms its centre will be the background to the portrait statue, and one of the accessory groups of sculpture will face Piccadilly. The monument is, in fact, and all-round one, with an important sculptural group on each face. We quite agree that, as it is to be placed in that position, the statue of the King should face towards the Queen Victoria Memorial. Another objection made to the site is that the space is not adequate, as to appearance, for a monument on so large a scale. The whole erection will be 43 ft. high, 21 ft. wide, and 16 ft. deep. For a monument on that scale there ought to be a fairly large square space, treated in a decorative manner, surrounding it. For this some amount of land would have to be taken off the Green Park. It was intimated that any proposal to do this would be likely to meet with opposition in Parliament, as an encroachment on the rights of the public. Mr. Lawson, while in opposition to the scheme generally, made light of his objection, saying that "in this curious House of Commons there would be an objection to anything," which is probably true. But the idea of objecting to take some pace from the green of the Park on the ground of public rights is absurd; it would not be ground taken from the public enjoyment, it would only be ground differently treated in order to give the best effect to the memorial; and that would surely be an addition to the public enjoyment, not an interference with it. And to get the best effect of so large a monument that ought to be done; otherwise it will look too large for its position. A monument on that scale requires some open space round it.

Though the objections to the site have been exaggerated, it must be admitted that it is not entirely satisfactory. It is spoken of as facing the Queen Victoria Memorial, but to face the front of one monument towards the flank of another is not a true form of axiality. We are still of opinion that the finest and most suitable site would have been at the east end of the Victoria Memorial Road, facing west towards the Victoria Memorial and on the same central axis with it. The new building at the east end of the Road would then have formed a fine architectural background to the monument, and there would have been a suitability, both of architectural effect and of association, in having the two monuments facing each other on the axis of the road. The

roadway is quite wide enough for that position, both in an artistic and in a practical sense, and we can only regret that this site has not been adopted.

As for the monument itself, as far as one can judge from a model, it appears to deserve nothing but praise, and it is to be hoped that after its exhibition we shall not hear any more of the ignorant grumbling that has been made as to the appointment of one of the ablest sculptors of the day, of whose works and of whose claims to respect his amateur critics appeared to know nothing. And the satisfactory character of the design is partly due to the fact that in this case at least the Government have adopted the practice, always adopted for public monuments in France, of appointing an architect to collaborate with the sculptor and to design the architectural basis of the work. The treatment of the pedestal, and of the architectural centre with which the figures are grouped, is a very important element in the total effect of a monument, and it is one which few sculptors understand. Had the same course been taken with the Queen Victoria Memorial the result would probably have been much more satisfactory than it is.

The idea, in a monument to an eminent person, of accompanying the portrait figure by emblematical figures symbolising certain qualities or ideas having relation to the central figure is an essentially French one, and has been constantly employed for public monuments in France for many years. Generally speaking, the French artists content themselves with a portrait bust only, and thus avoid the difficulty of representing modern costume, which is so unsuitable for sculpture; and they are then free to treat the subsidiary symbolical figures in a purely abstract and sculptural manner. Thus, in M. Larche's charming monument to Corot, we have only the bust of the painter on a pedestal crowned with a wreath presented to him by a nude nymph who seems to symbolise the spirit of his own woodland scenery. This method of treatment has been adopted in one beautiful English work, Mr. Gilbert's monument to Fawcett, which stands in a dark corner of the nave at Westminster, where few people ever see it. This consists of a medallion head of Fawcett in relief, and a row of seven small bronze figures beneath, representing various virtues; both a poetical and a sculptural manner of treating a monument. We are rather inclined to think that both the Victoria and the Edward VII. monument designs would have been better if the portraits had been busts only; but in the case of the latter the sculptor has the advantage of the long ceremonial robe, which is capable of broad and effective treatment in sculpture; unlike the realistic frock-coat of ordinary modern dress, which is hopeless for sculptural effect, as many English memorial statues unhappily testify.

The idea of the design is to give the figure of the late King in front; on the right a seated figure symbolical of hospital work, and bearing the snake-wreath staff of Æsculapius; on the left a seated figure representing Peace, with appropriate emblems; at the back a bronze group representing "Arbitration quelling Strife," which one hopes may be symbolical of the future as well as of the past. No one will deny that King Edward VII. fully earned the right to these symbolical groups on his monument. The St. George and the Dragon, which makes an effective terminal group, one may suppose to refer to England at large, giving a specially national character to the memorial. Above the side figures are the Royal Arms in bronze and stone. The architectural

portion of the monument will be in Portland stone, the sculpture in bronze.

We may congratulate Mr. Lutyens on his pedestal, which is exceedingly well treated in a thoroughly masonic spirit, and the sculpture sits well upon its bases, giving an expression of unity and concentration to the whole work, which promises to be something far superior to the general run of public monuments in this country.

Cheap Cottages.

ANOTHER correspondent of the "Spectator," we are glad to see, has written a sensible and practical letter to protest against the proposals for tarred wooden cottages as country dwellings. He says, as we did, that in new buildings we should take advantage of modern knowledge as to fireproof materials and reinforced concrete, "which last would enable us to build sound walls much less ponderous than of old." We may quote another passage from Mr. Robinson's letter:—

"As to the cottages of the future, where several are required a new departure should be made in their construction. The great enemy is the sloping roof with the vast quantity of timber it entails. A better way would be to build the cottages two storeys high, with fireproof floors and a flat roof, with a very gentle rise in the middle to throw the water off, and a low parapet all round, and each upper cottage with a separate entrance in the Italian way by means of an outside staircase. In this way we should secure in a not expensive way cottages fireproof, vermin-proof, rot-proof, and sanitary.

"The sloping roof of tiles and slates, unless done in the best way, which a cottage cannot afford, is a continual cause of trouble and expense."

This is the common sense of the matter, but, of course, the editor of the "Spectator" is "profoundly in disagreement" with the correspondent who, with evidently better knowledge, has presumed to condemn his suggestions.

Christchurch Priory.

IT appears that there is to be a rearrangement of the interior of the fine Priory Church of Christchurch, Hants, under the direction of Mr. T. G. Jackson, and that the stone choir screen, the removal of which to another position has been urged at different times, is to remain where it is, and to become the reredos of the parish church, a choir and sanctuary being formed between it and the congregation. It is not quite clear from the account in the "Bournemouth Guardian" what is to be done with the portion of the building east of the screen. We conclude that it is to be left outside of the ritual church and to remain merely as a piece of architecture unconnected with the use of the church for worship. The former proposals to remove the screen arose from the complaint that it shut out the east end of the church too completely from the congregation; so that to make it a reredos, without interfering with its position, is probably the best thing to do with it. It is stated also that the transept galleries are to be removed. There is (or was) a large and fine organ in the south transept gallery; what is to be done with that?

The Indian Victoria Memorial.

IT appears that Sir W. Emerson's great building, which was to be erected at Calcutta as a memorial to Queen Victoria, is proving a kind of white elephant which the authorities are now anxious to get rid of. There was some unfortunate trouble in the first instance with the foundations, which, as far as we remember, was by no means the fault of the architect; and apparently the building has never got beyond the basement storey. Now that the seat of the capital is to be removed to Delhi, it seems to be considered doubtful whether Calcutta can make any use of such an immense building, and whether the money required for completing it could not be better employed in the promotion of education. This may be thought to be common

sense, but it is a rather discreditable sequel to a great monumental scheme to treat it merely as an economical question; and it is not a way of doing honour to the memory of the first Empress of India. Surely it would be better, and more honourable to the Empire, to carry out the monumental building from the same design at Delhi; the new capital, and put up with the loss incurred on the foundations of the Calcutta site. There is something very inglorious in the idea of the Indian Government having begun a great monument to the late Empress, and being too parsimonious to complete it; and the incident is not calculated to raise our reputation with the native princes of India.

The Institute Prizes and Studentships : 1913.

THE scheme has just been issued of the students' competition subjects which will be adjudicated by the Institute of Architects at the close of the present year. We notice one important change in regard to the Essay Prize; instead of a special subject being appointed the prize is to be awarded for the best essay on a subject of architectural interest chosen by each competitor for himself. The essay prize has hitherto been rather a failure as regards the response to it; sometimes there has been no response, sometimes only one or two essays. Apparently it is thought that to leave the choice of subject to the competitors themselves may lead to a better response. Perhaps it may; often a young man has some subject which interests himself and on which he has collected some information and he may find it much easier and pleasanter to write an essay on that than on a subject chosen for him. The arrangement will rather increase the difficulty of making a comparison of merit; but in other respects it seems a good idea.

The subject for the Soane Medallion is "A Terminal Railway Station"; a very good subject, in the treatment of which it is to be hoped that some of the competitors may strike out some fine and effective idea for the architectural treatment of a large railway station façade—something which is obviously a railway station and could be nothing else, and which would architecturally symbolise the importance of a great railway line. The characteristic treatment of railway station façades has in practice been rather interfered with by the common requirement of a large hotel in connexion with a railway station, which is generally placed in front, so that the station façade becomes merely one more hotel, with little to differentiate it from an hotel in any other position.

For the Tite Prize the subject is "The Façade of a Royal Palace in a City," approached by a wide avenue, with three carriage entrances to an assumed interior courtyard; the façade to be 300 ft. long and four storeys high. Something fine ought to be made out of this.

The Grissell Medal (which is given specially for constructional work) is to be awarded for the best design for "A Riding School constructed of steel with the sides and roof partially glazed." The walls are to be filled in between the steel framing with brick or other fire-resisting material and the steelwork of the roof and walls to be exposed to view. There is room in such a scheme for experiments in design as well as in construction. If the competitors could get hold of illustrations of the "Palais des Arts Libéraux" in the 1889 Paris Exhibition, which was constructed much in the way here proposed, they would find a good deal of useful suggestion in the treatment of the same general problem by one of the ablest French architects of the day.

The Basilica Plan for Churches.

IT is rather a singular coincidence that, while we are printing in another column a paper ("Architecture Considered in Relation to Music") in which the basilica type of church plan is recommended as affording the best plan for modern worship, in place of the Gothic plan, wit-

the long chancel, an account reaches us of a church on that plan just about to be erected in Bradford, from the design of Mr. G. S. Nicol, of Birmingham. It is described as providing "a large uninterrupted space for a congregation, with no break in the architectural lines to distract attention from the altar, which is enshrined at the east end in a semi-circular and semi-domed apse." This appears to be practically the Latin basilica plan, only that the description does not say whether the nave is divided up by arcades or not. Nor does it state how the choir and organ are to be placed, which is a practical point of some interest in church planning. But we are rather inclined to think that this adoption of the basilica form of plan for modern churches is likely to be considerably extended in the future.

Iron versus Stone Bridges.

UNDER this heading a Cumberland paper publishes a report of a meeting of the Penrith Rural District Council, when the subject of new bridges in the district was discussed, with the contempt usually shown in such discussions for any considerations but those of immediate economy of construction. The Council wish to build iron bridges all over their district wherever new bridges are required; and in reference to a protest which had apparently been made by Canon Rawnsley on the subject, one speaker observed that "they did not care about pleasing artistic faddists or antiquarian cranks," the kind of compliments usually passed upon those who have some regard of the beauty of a district. The Council do not seem to be aware, and probably do not care, that in substituting iron for stone bridges they are taking the best way to disfigure the country. Nor is the boasted economy a real one, except for the moment, for a well-built stone bridge, besides looking much better in a country landscape than an iron one, will last a longer, and require no painting or repairs.

"No Right to Dictate."

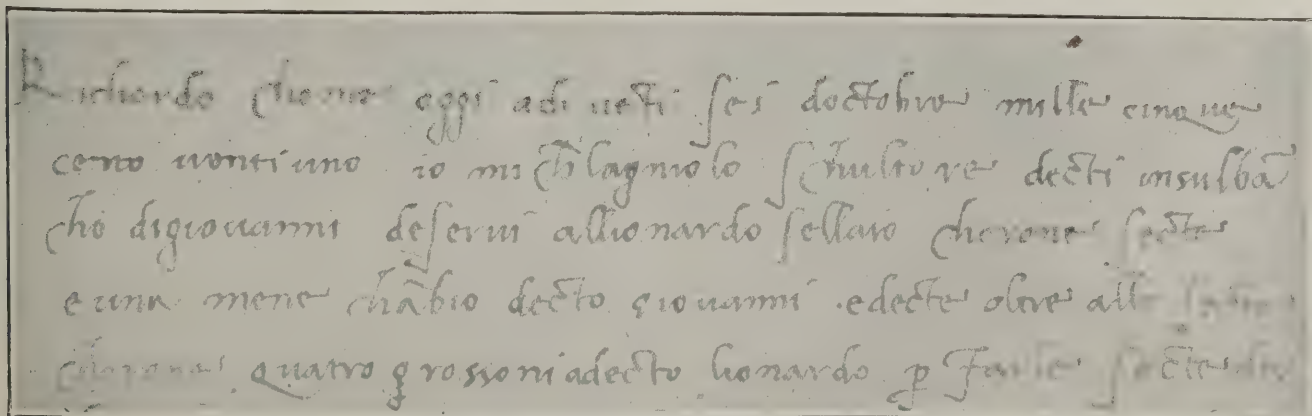

IN the conditions of the competition arranged by the Warrington Education Committee for designs for a new Council School at Oakwood Avenue, no provision was made for the appointment of a professional assessor. This serious omission was promptly pointed out by the Manchester Society of Architects, but the Sites and Buildings Committee declined to alter the conditions. When, last week, the minute relating to the case came up for discussion by the Education Committee, an amendment was moved to the effect that the matter should be referred back, "on the ground that non-compliance with the society's recommendations would debar the cream of the profession from competing." The chairman of the Sites and Buildings Committee said that "the society had no right to dictate to the committee as to what they should do," and the amendment was lost. These high-sounding and familiar catch-phrases are usually very deadly. Nobody thinks of analysing them, and so they pass for authoritative and, indeed, axiomatic truth, to which opposition is vain, if not wicked. Take this specimen—that "the society had no right to

dictate to the committee." What, precisely, does it mean? It involves several pure assumptions or insinuations; as (1) that the society had assumed a domineering attitude, and must be put in its place with the reminder that We, not ye, are the final authority in this matter; (2) that the society had ever assumed any right in this sense; and (3) that the society really had no *locus standi* in these high matters, and should not have the effrontery to intervene; (4) that the committee is too august a body to tolerate such interference; (5) that, even assuming, for the sake of argument, the possibility that the committee could err in tactics, the fact that the error was pointed out by the society was ample justification for persisting in it. As to (1) there can be no doubt that the society approached the subject with all due regard for the customary forms of courtesy, and did not make the egregious mistake of assuming a dictatorial air, or (2) any right to dictate or command. Regarding (3) it is surely superfluous to claim that the society has every right to safeguard the interests of its members, and (4) that no committee, howsoever august, should affect to be as unapproachable as the Grand Llama or as infallible as the Pope; nor (5) as stiff-necked and implacable as the Pharaoh of the plagues. The temporary gratification of the act of standing on one's dignity can be too dearly bought. The principle involved is well worth a struggle, and so generally recognised that it is surprising that at this time of day any public body should oppose it. The appointment of an independent assessor is as advantageous to the organisers of a competition as it is to the competitors, relieving the former of a weight of responsibility which, as ordinarily constituted, they can seldom or never safely assume, and to the latter giving assurance that their work will be professionally adjudicated upon. The "right to dictate" is not claimed; the right to protest is indefeasible.

Autographs of Great Painters.

AN exhibition of extraordinary interest is to be seen in the outer room of the Leicester Gallery at present, being a collection of a number of complete letters by eminent artists, from Pollajuolo to Millais; not mere signatures, but complete letters, some of them of great interest. Of twenty-one of the artists represented here, there is no autograph even in the British Museum.

One of course looks with considerable interest at the mere handwriting as characteristic of times and personalities. A general look through the collection shows at once that the Italians of the Renaissance wrote the finest and most artistic hands; the French of the later Renaissance come next, and the English painters of the eighteenth and nineteenth centuries are the poorest. The contrast between their writing and that of the Renaissance Italians is rather painful. In the latter we see the work of men who would make even a letter a work of art; in the English letters, mostly of later date, there is nothing to admire in the writing at all for its own sake; it merely gives the information required, and all one can remark is that some hands are more or less legible than others. Among the Italian

SPECIMEN OF MICHELANGELO'S HANDWRITING

etters the single example by Raphael is a perfect gem of delicate, finished, and artistic writing; with all its finish it is quite free and flowing, and seems to be the artist's natural style of penmanship, not a neat copy made for a special occasion. The contrast between this and Michelangelo's writing is curiously characteristic of the two men; Raphael's full of delicate grace, Michelangelo's robust, upright, decisive in character, and written with a much thicker pen than Raphael's. We show a reproduction of one of the Michelangelo specimens, from the catalogue, in which a good many facsimiles are given, so that it becomes a document of some value.

Two of the most interesting letters in the collection are two by Rubens, not remarkable for their calligraphy, but for the evidence they give of Rubens's general interest in contemporary life and politics; one would take them, in fact, to be the letters of a statesman rather than a painter. It is noticeable that both letters are in Italian; a letter by Nicolas Poussin, dated 12 years later than Rubens's, is also in Italian. Why do we find a Dutch and a French painter both writing in Italian? It looks as if, in the seventeenth century, Italian was the language [of intercommunication for artists, just as French has become the language of diplomatic intercourse.

One of the most interesting letters is one by J. F. Millet, dated June 1st, 1838 (he was then 22 years of age), in regard to his having been unsuccessful for the Prix de Rome, and having almost given up the idea of trying again, but he had reconsidered this: "Why should I renounce the pleasure of dreaming among those beautiful ruins where we shall see, walking in the twilight, the long-draped majestic forms coming again to think over the affairs of the Senate, with one of these forms conducting us?" This is accompanied by a sketch showing a long-robed Senator expounding the ruins of Rome to Millet and a fellow-student. He never obtained the Prix de Rome, having been told the next year (practically) that Roux was to have it, but that he would undoubtedly have it the year following. Millet did not care to go on competing for a prize which no doubt seemed to him to be too dependent on arrangement. Had he ever gone to the Villa Medici, probably his whole career would have been altered and we should never have had "The Sower" or "The Angelus"; but it is possible that we might have had something still better. Millet's little-known early pictures, before he took to painting rustic life, are artistically the best things he did. To return to the matter of handwriting, by the way, it may be observed that Millet's writing is exceedingly bad and untidy, and has not the slightest artistic character.

ARCHITECTURE CONSIDERED IN RELATION TO MUSIC.

BY H. H. STATHAM, F.R.I.B.A.

WHEN Mr. Worthington was kind enough to invite me to read a paper before the Manchester Society of Architects, he suggested as the subject "Architecture and Music." I thought that rather too vague, and I subsequently found the title was put down as, I think, "The Construction of Buildings for Music." That is a little too exclusively practical, and I prefer to regard my subject as "Architecture considered in relation to Music," as that leaves me the opportunity of saying a few words, to begin with, on the æsthetic resemblances between architecture and music. It is a parallel which must not be pushed too far, but there is really something of interest in it, not altogether uninteresting.

The most essential resemblance between architecture and music is that they are both arts which deal with abstract qualities of proportion and balance of parts, not with direct imitation of nature. That is the main element in which they differ from sculpture and painting. The objects of painting and sculpture go of course a great deal further than the imitation of nature, but they are based on that; they are the expression of design and of sentiment in terms of natural

forms, so that they may be said to be physical arts. Architecture and music are based upon qualities which underlie the physical forms, on line and proportion as abstract qualities, so that they may be called metaphysical arts. Music is line and proportion expressed in time; architecture is line and proportion expressed in space. The great difference in our appreciation of design in the two arts—and it is rather a curious one to consider—is that we can see and grasp the architectural design and its proportions at once, but we can only grasp the proportions of musical design by an effort of memory. If you can imagine a man with a good ear for tone but absolutely without memory, that man could never appreciate any musical composition at all, because he would only be conscious of the sound made at the moment. The musical compositions of the great composers are built up with as strict regard to the proportion and relation of the successive parts as an architectural composition is; but we are only conscious of that proportion, at any given moment of sound, by the recollection of what preceded it. It is as if you had to judge an architectural elevation by looking at it through a very narrow slit in a screen, and having the drawing slowly drawn past in front of the screen.

A quality which the two arts have in common is that of rhythm, the succession of impulses at exactly equal intervals, which can occur either in space or in time. But in music rhythm is a much more inherent quality than in architecture, for the very existence of musical tones depends upon the rhythmical succession of the vibrations. If you strike a table, say, with a hammer, if you could see the vibrations of air caused by the blow, which are in fact the sound, you would find that they form an irregular bunch, with no rule in their succession; but if you produce a musical sound by drawing a violin bow across a string, the vibrations will be in a regular succession of equally spaced periods. There is no phenomenon similar to that in connection with sight; but there is a comparison possible between music and architecture, and an instructive one, if you compare rhythm on a larger scale. All musical compositions which are stately and grand in expression are marked by a regular recurrence of accent at equal periods of time; and the same is true of architecture; stateliness and monumental expression can hardly exist in architecture without symmetrical spacing of parts at equal distances in space.

There is another point in regard to which music and architecture may be compared in a sense which is not generally recognised. The distinction between concords and discords in music is entirely a matter of numerical proportion in the rate of vibrations. Two notes form what is recognised by our ears as a concord when their rates of vibration per second are in comparatively simple ratios. In two notes an octave apart, which is the most complete concord there is, the respective vibrations are as 1 to 2; in the interval of a fifth, which is the next most complete, they are as 2 to 3; in the interval of a third they are as 3 to 4. When you get to less simple ratios than that, the combination ceases to be regarded as a concord. All people have not naturally the perception of the minute differences of pitch which mark off a complete from an incomplete concord—those are the people who cannot sing in tune; but the perception may be very much improved by practice; pianoforte tuners, for instance, who are always at it, develop an exceedingly sensitive ear for intervals. Most eminent musicians have the perception of pitch very completely. One of the most remarkable instances ever heard of was related of the late Sir Frederick Ouseley. He had been abroad for two or three months, and on revisiting the organ, I think at York Minster, which he had been in the habit of playing on, as soon as he touched it, he said to the organist—"What have the tuners been doing here? The organ is an eighth of a tone sharper than it used to be." A tuning fork was produced, and he proved to be right. What has this to do with architecture? Well, this: we know that the Greeks attached great importance to the proportions of parts in their buildings, and it has been argued sometimes, with considerable show of reason, that there could be no value in minutely adjusted proportions as to which the eye could not well judge whether they were strictly accurate or not.

But is it certain that the Greek eye could not judge of them? Is it not possible that the Greeks had so cultivated their sense of proportion in things seen, that a proportion of parts which was not in the right ratio of measurement affected their eyes disagreeably, just as a wrong proportion in sounds affects the modern musical ear disagreeably? We have no proof of it, but it is quite possible it may have been so, and that the impression of perfection we get from the best-preserved remains of Greek architecture may be due to the fact that the Greeks had cultivated the sense of sight as the modern musician cultivates the sense of hearing. Perhaps the corollary might be that we might do wisely to cultivate more carefully our own sense of proportion in things seen by the eye.

The sense of proportion in masses comes into music just as it does into architecture. When Beethoven wrote the third of the four experimental overtures to his one opera—that now known as *Leonora No. 3*, which is quite the finest of the four—his friends told him it was too large in scale for the Opera, which is only a two-act one. They were quite right, and he admitted it by writing the fourth and lighter one. The other one would have been like an entrance lodge that is too large and pretentious for the house. This sense of proportion of parts runs through all the works of the great composers; Mozart's and Beethoven's symphonies are models of the subordination of detail to the leading idea. There is a curious parallel, too, between the two arts, in the method of leaving off. Every composition ends with what is called the common chord of the key it is written in; that is, the most harmonious combination of keynote, third, fifth, and octave; but a big composition is never snapped short off with one sounding of the chord; it has to be repeated several times, sometimes many times, to make an adequate stop. Just so we dominate an important building by a strong horizontal cornice, to cut across the lines of composition and make a decisive finish. And you will find lighter compositions, like Chopin's waltzes and some of Mendelssohn's *Songs without Words*, end with a rippling flourish running up to finish on a high note, like a pretty summer-house that ends in a spirelet or a pinnacle.

Both music and architecture can express character, which is a lighter element than beauty or grandeur; character sometimes arises as much from what is left out as from what is there. The difference between the two is that music can express or symbolise human character and events; architecture can only express artistic character. A good example of characteristic music is the symbolising of the village merry-making in Beethoven's "*Pastoral Symphony*," with the rough dance tune and the bassoon player who can only play two notes. It is just like one of Teniers's pictures of boors dancing; but it is not the best part of the work in a musical sense. Whether in music or architecture, if you want character, which is a half-playful quality, you have to give up something of the higher elements of the arts. One of the best pieces of character I have seen in architecture was the *Pastellistes' pavilion* in the 1900 Paris Exhibition. I knew there was a *Pastellistes' pavilion*, and was looking for it, when I suddenly caught sight of it, unmistakable from its character. Pastel is a kind of lighter and more playful treatment than oil painting, in a slighter medium; the pavilion was a light and playful treatment of Classic architecture; the colour too, a light green and white, helped the expression; it seemed to suggest pastel tones. It was one of the cleverest pieces of character in architectural design I have ever seen.

Now I have done with my æsthetics, and we will come to the practical side; the construction of buildings for music. Opera-houses are purposely left out of my scheme; they are concerned also with spectacle, and form a subject by themselves; we are concerned now only with buildings for hearing music. It is remarkable that many important buildings of this class have been erected without the slightest thought of their suitability for their purpose. St. George's Hall at Liverpool is a notable example. Liverpool used once to have triennial musical festivals, held inconveniently in a large church. It was decided that Liverpool must have a large hall for such purposes, and a competition was advertised for a building to contain such a

hall and the Law Courts. It was won, as you know, by Elmes, a real genius in architecture, who produced what is at once one of the finest halls and probably the worst interior for music in the world. The principal reason why it is so bad will be referred to later, but it may be said at once that Elmes scoffed at the whole idea of thinking of the music, and was even angry that there would be a large organ in the Hall; it would spoil his architecture. We have got a little further than that now; yet I saw a very recent accepted design for a large concert hall where the approaches were admirably planned, but the orchestra was badly placed, and too small, the space for the organ much too small in area; and as there was no height for the large pipes, they were to be carried up in a sort of tower, so that they would be practically out of the hall. It seems to me that when there are competitions for concert-halls either an assessor should be appointed who knows something of music, or that an architect and a musician should be appointed as joint assessors.

New concert-halls are almost always, on the part of the promoters, commercial rather than artistic speculations, and one of the first things generally thought of is the capability of letting the hall for other purposes than concerts. That generally means a flat floor, and after that any idea of making the best possible building for hearing music is at an end. The only thing one can say is—if you must have a flat floor, do not have a solid wood-block floor, on concrete. That is supposed to be the orthodox floor for a public room now, but it is bad for music. You need a boarded floor with a space underneath, to act as a resonator. It is all very well to talk about danger from fire; but one cannot have everything, and if a building is to be the best for music that risk has to be run.

In constructing the best possible building for music we have three main points to consider: (1) efficient production of sound; (2) avoidance of echo; (3) placing the audience in the best and most convenient way for hearing. In regard to the point of production of sound, the orchestra must be built of wood and lined either with wood or with fibrous plaster; materials which sympathise with sound without absorbing it. Textiles absorb sound; there should be no curtains or upholstery about the orchestra. On the other hand, there should be no hard polished surfaces; they do not assist sound, but they may have the result of imparting a hard metallic clang to it. The walls of the orchestra should widen somewhat towards the auditorium, and the ceiling slope gently upward from back to front; and the ceiling should not be higher than can be avoided, as we do not want the sound up there—we want it driven forward towards the auditorium.

The avoidance of echo is a question partly of the materials used and partly of the shape of the room. In regard to material, all substances which reflect light sharply will reflect sound sharply; polished marble and hard polished cements should be avoided. It is those which render St. George's Hall so bad for music; the interior is all marble and hard cement, and the echo when an elaborate composition is played on the organ is such as to confuse the whole thing. It is an extraordinary fact that the late Mr. Willis, who built the organs both at St. George's Hall and the Albert Hall, advised the Albert Hall Committee to pave the floor with tiles and line the walls with hard polished cement; in other words, to repeat in the building the very defect which injures the effect of the St. George's Hall organ. The reason was probably this: a single chord sounded on an organ in a building with much echo, or a piece of slow music played on it, gets a kind of fine rolling effect of prolonged tone; but we want not only tone, we want clear definition of music; and the echo, though it may add an effect to tone, blurs all definition. The moral is—never take the advice of an organ-builder on such matters; organ-builders know how to make mechanism and to voice the pipes, but they know nothing else. The best material for lining walls is fibrous plaster, or a wooden dado with fibrous plaster over it. It is probably due to the employment of that material that the Albert Hall, considering its size, is remarkably free from disturbing echo. There should never be plate-glass windows in a concert room; they

form sharp reflectors of sound; windows should be in small panes with wooden bars, not metal. When the Albert Hall was first built, the echo from the concave glass roof was something distracting; now they have hung a "velarium" under it, and the echo is all gone, swallowed by the velarium; a good example of the effect of textiles in deadening sound, in this case with a beneficial result.

Then we come to the shape of the room as affecting sound and echo. Now on this subject it must be understood that there is no science of acoustics worth speaking of. Acoustics can give us positive information as to the manner in which sound is produced, its rate of travel, and so on; but there is no scientific law which will enable us to predict exactly what sound will do in a room of a certain size, shape, and material. It seems to depend on a number of circumstances which are beyond definite analysis. Of course we know that in the report accompanying a competition design for a concert hall we always read—"The question of acoustics has been carefully considered"; but the statement hardly counts for much. All that we really have to go upon is a certain degree of experience, which shows that some shapes and some materials are to be avoided, as being likely to produce bad results. There is no exact science about it; success depends on experience and observation only, coupled with common sense.

In Roger Smith's little book on "Acoustics" it is stated that a right-angled meeting of walls, if sound is produced near the angle, leads to a noisy repercussion from side to side, which gets repeated at the opposite angle; I have not tested this, but I think it is very likely to be so, and that therefore it is better to have the meeting of walls, and of wall and ceiling, broken by a plane at an angle of 45° ; or, what would probably be still better, by a convex angle screen. A concave surface focusses echo, if there is any; a convex one spreads and disperses it. Then, smooth flat surfaces on walls and ceiling should be avoided. A flat end wall, in a large concert-hall, is almost certain to send back disturbing echoes; its surface must be broken up in some way; for this reason a gallery across the end, besides adding to the seat-room, is sometimes an acoustic advantage. If the side walls are quite smooth, it has been found that sound produced at one end of the hall will tend, when it strikes the wall at each side, to run along the wall and be echoed back from the end. The smooth wall is the cause of the effect in what is called the "whispering gallery" at St. Paul's; a man speaks against the wall, and as the wall is perfectly smooth the sound runs round it and is heard at the other side; if the wall were broken up by pilasters there would be an end of the joke. For the same reason, if in a hall with a circular end and quite smooth walls a sound were produced at A (Fig. 1), I expect that a hearer stationed at B would hear that sound doubled; he would hear it first by the shorter route across the hall, and a fraction of a second later he would hear the wave of sound that had run round the curved end and up the other side. But there would be no such effect if the wall were broken up by pilasters. Generally speaking, however, concave surfaces, either in wall or ceiling, are better avoided; they tend to focus an echo on the centre of the curve, and this should be noticed, because there is a tendency at present towards circular plans for concert-rooms. Echo may be prevented in them by judicious use of materials and wall treatment; but there are various instances of circular rooms in which a whisper at one side is heard plainly at the other side. As reference has been made to the effect of textiles in deadening sound, it may be said that textiles, curtains for instance, at the opposite end from the orchestra, may have rather a good effect in preventing any return echo, though they should not be used prominently in any other part of the room.

We now come to the question of the best way of placing the audience, and the first thing to be remembered is that the audience should "face the music." For this purpose the circular form is very bad. This is shown in the upper

part of Fig. 2, which is the half-plan of the Albert Hall. The plan is, in fact, a perfectly absurd one for a building in which music is to be performed by an orchestra at one end, as it is an imitation of the Roman amphitheatre plan; a plan specially constructed for the sight of a spectacle in the central arena.

FIG. 2.

This might do fairly well for instrumental music only, if the band were placed in the arena, but would be impossible for choral music. So the orchestra is erected on the smaller curve of the ellipse. The result is that the part of the audience seated to the left of the dotted line have the sensation of sitting, not facing, but side by side with, the performers; they can only see them sideways, and they hear one side more than the other. The seats might be arranged as shown in the lower half of the diagram, but it is a very awkward form of plan to arrange seats on. The Queen's Hall is a semicircle facing the orchestra, merging into a piece of straight gallery on each side, running towards the orchestra. This again is bad, for in these straight portions the audience are again quite on one side of the performers, not facing them. The Liverpool Philharmonic Hall, in many aspects an exceedingly good room, with no echo, is a long rectangle in which all the audience on the ground floor face the performers, and for this part of the room it is about as good as a flat-floor concert-hall can be, and the approaches are admirably arranged. The mistake is up above, where there is a series of side-boxes above the ground-floor corridors, and above them long side-galleries on a considerable slope. Both these are bad places for hearing, except in the front row; and even there it is inconvenient to be sitting sideways to the music, for however it may be said that we hear with our ears and not with our eyes, there is always the wish, half-unconscious, to see the performers at the same time. I say, therefore, that side galleries in a concert-hall are a mistake.

The best plan for a concert-hall is a parallelogram about twice as long as it is wide, exclusive of the orchestra—or perhaps the proportion of width might be a little greater—with the floor rising from front to back, not quite in a straight section, but in a slight curve, becoming rather quicker in its rise towards the back, and set out so that the back row of listeners should be about on a level with the half-height of the orchestra. The seats should be all across the width of the room, facing the orchestra. The reason for having the seats raised on a slope or curve is that, however one may think theoretically that it ought not to be so, it does seem to be the fact that sound tends to rise more than fall from the point of production, and anyone seated at the back of a large flat-floor concert-room has the impression that some of the sound is over his head. That this is not a mere impression is proved by the fact (to which I can testify from experience) that at the Handel Festivals at the Crystal Palace one hears the total effect far better in the transept galleries than on the ground floor. The ceiling of the room should not be a very high one, because the area where no one is listening means wasted sound; we want to confine the sound in the direction of the listeners. And that implies another objection to the circular form for large concert-halls. Such a hall leaves a wide central air-space where sound wanders about uncontrolled, and the sharpness of detail is lost. I have been strongly conscious of this in listening to orchestral music in the Albert Hall. You lose musical detail in so large a space. And on this account I would raise a protest against the tendency to

FIG. 1.

FIG. 3.—SECTION AND PLAN [FOR A NEW CONSTRUCTION OF THE ORCHESTRA.

increased size in our concert-halls. I do not believe it is possible for more than 2,500 people to hear music satisfactorily in one building, and I should prefer to limit it to 2,000. The Queen's Hall seats 2,650, and is, in my opinion, too large for the most perfect enjoyment of music.

There is, however, one class of concert-room in which the circular form might be well employed; in rooms on a small scale for chamber-music. When you come down to small dimensions you are not much troubled about echo; there is not space for it to develop. String quartet music in large halls is a mistake; the scale of the music is too small for the building; it is like a cabinet picture in a gallery intended for large pictures. In the chamber concerts of the Musical Union in London, which were given in the old St. James's Hall, the room was specially arranged for the occasion; a temporary platform was erected in the middle of the floor, and the seats placed facing towards it on all sides. This was much better than having the players on the platform at one end; but still the hall was too large for the music. But a small circular concert-room, with a platform in the middle for the players, might be very good for chamber music concerts, and a charming room might be made of it architecturally. It would not, of course, do for vocal music, where the singer must face the whole of the audience; but it would be perfectly efficient for instrumental music, and would enable a fair number of persons to be seated without any of them being far from the performers.

I have now to make what I believe is an entirely new suggestion for the construction of the orchestra for the combination of band, chorus, and organ. At present there is no structural division between band and chorus; they are crowded close up together so that the back row of the instrumentalists is close up to the front row of the singers. There is a double disadvantage in this. The band is imme-
